Mr. Ritchie, President of the Board of Trade, returned from the Whitsun holidays with a sprained ankle which he got while cycling in the country. He was only able to walk into the House with the aid of two stout sticks, and when the Light Railways Bill, which is under his charge, came on and divisions were frequent the Speaker made a dispensation in his favour and allowed him to record his vote at the table instead of going to the division lobby each time.

HOUSE OF COMMONS.

MONDAY, JUNE 1ST.

The Snowdon Railway Accident.

In reply to a question Mr. Ritchie, President of the Board of Trade, stated that the engineers were of opinion that the accident on the Snowdon Railway was caused by the locomotive mounting the rack, probably in consequence of a subsidence of the permanent way due to the melting of snow in a cutting. As the line was not constructed under any statutory authoritery the provisions of the Railway Acts as to inspection did not apply, and the Board of Trade had no power in the matter. On the recommendation of the company's engineers no passenger traffic had been carried since the date of the accident, and none would be carried pending the adoption of certain additional precautions suggested by the engineer to prevent the engine mounting the rack.

TUESDAY, JUNE 2ND.

Diseases of Animals Bill.

A large part of this day was devoted by the House of Commons to the consideration in Committee of the Bill of the Government to make statutory the present regulations prohibiting the importation of live cattle from abroad, and while a great number of amendments were proposed not one of them was carried, and the measure consequently proceeds to the third reading stage in exactly the same form as it was introduced.

Mr. Sydney Buxton, Under-Secretary for the Colonies in the late Administration, put forward an amendment enabling the Board of Agriculture to exempt from slaughter at the port of entry cattle arriving from any of the British colonies. He laid special emphasis on the case of Canada and said that the experience of three and a half years went far to prove the Canadian contention that if disease existed at all in Canadian cattle it was not contagious pleuro-pneumonia.

Mr. William Allan (Gateshead) said that the Canadian cattle were free from disease when shipped, but sometimes on board ship they caught what was called a "sea chill," which produced inflammation of the nostrils corresponding to human catarrh. From this they recovered after being a few weeks in this country.

Mr. Walter Long, President of the Board of Agriculture, in resisting the amendment, said that at the request of his predecessor in office an exhaustive inquiry into the question of the health of Canadian cattle was held by Sir Henry James and Dr. Burdon Sanderson, and anyone who read the evidence taken by those gentlemen must come to the conclusion that it was clearly established beyond all doubt that contagious pleuro-pneumonia existed amongst cattle imported from Canada. He was confident that the Canadian Government did their best to save their herds from infection; but their great difficulty was that they had a frontier thousands of miles in extent, and that on the other side of that frontier, in the United States, pleuro-pneumonia existed, as the Canadian Government admitted. The Canadian Government did their best to protect themselves from the importation of the disease from the United States; and the Government of the United States took exactly the same view of the action of the Government of Canada as the Canadian Government took of the action of the Imperial Government—namely, that contagious pleuro-pneumonia did not exist in their country and that the prohibition of their cattle was unnecessary and harsh. But it was not the fact to say that there had been no cases of the disease discovered amongst Canadian cattle since 1893, when the inquiry was held. Eight cases were discovered in 1893, six in 1894, and two in 1895. There could be no doubt whatever, from the evidence of the scientific advisers of the Board of Agriculture, that the disease found amongst the cattle was not, as the Canadian Government asserted, simple pleuro-pneumonia or transit pneumonia, as the hon. member for Gateshead contended, but contagious pleuro-pneumonia; and that being so, it was impossible for the Agricultural Department, in justice to the stock owners of this country, whose interests they were bound to safeguard, to accept the amendment.

When the amendment was taken to a division 57 members voted for it and 140 against it.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ALEXANDER, B. ADOLPHUS, L.D.S.R.C.S.Eng., has been appointed Dental Surgeon to the Western Skin Hospital, Great Portland-street, London.

BLABER, P. L., L.R.C.P., M.R.C.S., has been appointed Junior Obstetric House Physician to St. Thomas's Hospital.

BLOUNT, G. B. C., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Electrical Department at St. Thomas's Hospital.

BROMET, E., M.A. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Physician to the Hospital for Women, Soho-square, W.

CHANING-PEARCE, A., M.B., B.S. Lond., has been appointed House Surgeon to the Kent County Ophthalmic Hospital, Maidstone.

CONFORD, G. J., B.A., M.B. B.Ch. Oxon., L.R.C.P., M.R.C.S., has been reappointed House Surgeon to St. Thomas's Hospital.

CROUCH, H. C., L.R.C.P., M.R.C.S., has been reappointed House Surgeon to St. Thomas's Hospital.

DE SANTI, PHILIP R. W., F.R.C.S., has been appointed Lecturer on Aural Surgery to the Westminster Hospital Medical School.

DIXON, C. A., M.R.C.S., L.R.C.P., has been appointed Junior Anæsthetist to the General Infirmary, Leeds.

DURRANT, C. E., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Ear at St. Thomas's Hospital.

DYBALL, B., L.R.C.P., M.R.C.S., has been reappointed Assistant House Surgeon to St. Thomas's Hospital.

FRAZER, W. D., L.R.C.P., M.R.C.S., has been reappointed Assistant House Surgeon to St. Thomas's Hospital.

HANWELL, G. L., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

HARTLEY, J., M.B., B.Ch. Vict., L.R.C.S., L.R.C.P. Edin., has been appointed Junior House Surgeon to the Ancoats Hospital, Manchester.

HAYNE, LOUIS B., M.B., B.C. Cantab., has been appointed House Physician to the Victoria Hospital for Children, Chelsea.

HICHENS, P. S., M.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.S., has been reappointed House Physician to St. Thomas's Hospital.

HILL, R. A. L., L.R.C.P., M.R.C.S., has been appointed House Surgeon to the Chichester Infirmary.

HODGINS, WALTER W., M.D., B.S. Durh., M.R.C.S., L.R.C.P., has been appointed Honorary Medical Officer to the Holloway and New Islington Dispensary.

JONES, MABEL, M.D. Lond., has been appointed House Surgeon to the Victoria Hospital for Sick Children, Hull, vice Miss D. Cox, M.B., resigned.

KENT, P. W., L.R.C.P., M.R.C.S., has been reappointed Assistant House Surgeon to St. Thomas's Hospital.

KNOCKER, W. D., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Electrical Department at St. Thomas's Hospital.

LAING, J. A., M.B., C.M. Edin., has been appointed Surgeon and Medical Officer to the Akaroa Hospital, New Zealand.

LAMBERT, P., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the No. 3 Sanitary District of the Newbury Union, vice F. H. Lyon, resigned.

LIGHTFOOT, CHAS. L., M.D., C.M. Edin., M.R.C.S., has been appointed Surgeon to the Northumberland, Durham, and Newcastle Eye Infirmary, vice H. W. Davies, resigned.

LYONS, EDWARD, M.B., B.Ch., B.A.O. Dubl., L.M. Rotunda, has been appointed Senior Resident Surgeon to the Jervis-street Hospital, Dublin.

MAUNSELL, JOHN, L.R.C.P., L.R.C.S. Irel., has been appointed Government Medical Officer at Enslow, Western Australia.

MORRISON, A., L.R.C.P., L.R.C.S. Edin., has been appointed Vice-Chairman of the Board for the Protection of Aborigines, Victoria, Australia.

NASH, E. H. T., L.R.C.P., M.R.C.S., has been appointed House Physician to St. Thomas's Hospital.

OLDFIELD, C., M.B. Lond., M.R.C.S., L.R.C.P., has been appointed Junior Anæsthetist to the General Infirmary, Leeds.

PALIN, E. W., M.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.S., has been reappointed House Physician to St. Thomas's Hospital.

PATERSON, W. H. J., L.R.C.P., M.R.C.S., has been appointed House Physician to St. Thomas's Hospital.

Digitized by Google

POTTER, E. FURNISS, M.D. Brux., M.R.C.S., L.R.C.P. Lond., has been appointed Acting Anæsthetist to the London Throat Hospital, Great Portland-street, W.

PRAIN, J. L., L.R.C.P., M.R.C.S., has been reappointed House Surgeon to St. Thomas's Hospital.

PRIDEAUX, C. S., L.D.S. Eng., has been appointed Honorary Dental Surgeon to the Dorset County Hospital, Dorchester.

RICHARDS, L. W., M.B., B.S. Durh., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

ROLSTON, JOHN R., L.R.C.P. Edin., M.R.C.S., has been appointed Honorary Surgeon to the Plymouth Royal Eye Infirmary, vice W. Square, deceased.

RUDDLE, R. G., M.D., Ch.B. Melb., has been appointed Medical Officer of Health for Mount Franklin Shire, Victoria, Australia.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

L.S.A. Lond.—The origin of the violation of Mr. Anderson's rights as a Licentiate of the Society of Apothecaries of London was that he attended Mrs. Marshall of Tobago both as a surgeon and as an apothecary. On being treated rudely by the husband Mr. Anderson retired from attendance on the case, which is one of necrosis of the inferior maxilla. For this retirement the patient and her husband brought an action against Mr. Anderson for £15 damages for negligence. It was proved by medical witnesses on both sides that there had been no negligence, that the patient had sustained no injury by the retirement, had recovered entirely through Mr. Anderson's treatment, and was nearly well when he retired. For the retirement from the case the judge gave damages of £10 and costs, made Mr. Anderson's charges for three months' attendance a counter claim, and deprived him of them on the grounds that a medical man has no right to refuse his services or to stipulate for payment for his services, or to retire from the case without the leave of the patient under any circumstances. The judge in this case, therefore, has violated Mr. Anderson's right to charge and recover for his services, and has punished him by damages and costs for the exercise of his rights as an apothecary. This illegal judgment was enforced by a levy on his effects, by imprisonment, excessive bail, and other violent measures. It is now declared that for these injuries done by judges Mr. Anderson has no right of remedy—i.e., that in the presence of judges Licentiates of the Worshipful Society of Apothecaries have no rights under their charter. (*Q. E. D.*) For full information *vide* THE LANCET of Feb. 29th, April 18th and 25th, and May 9th and 16th for articles on the Origin, History, and Objects of the Civil Rights Defence Committee, the secretaries of which (5, Mitre-court, Temple, E.C.) will be happy to send the reports post free and to give every possible information.

J. Kirkby.—We are obliged for our correspondent's communication and enclosures, but we fear that to comply with his request adequately would require too much space. The fallacies that surround the question and the unfounded assertions that are made over and over again by those opposed to this beneficent practice are legion. No amount of evidence can alter the fixed ideas that have taken possession of some minds. Read McVail's "Vaccination Vindicated," and Edwards' "Small Pox and Vaccination."

THE WRIGHT DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—The following additional subscriptions have been received or promised for the above fund since the issue of THE LANCET of May 16th. This brings up the amount to £52 15s. As this is far short of the sum required, the Committee have decided to keep open the subscription list a few days longer and solicit further subscriptions. I have had many suggestions from those who have kindly sent subscriptions in reference to Mr. Wright belonging to a defence union. It is, of course, to be regretted that he was not a member of a defence association, for then in all probability the case would never have been heard of after the first lawyer's letter. The fact of two defence associations being in existence makes many of us careless in not joining any. If we could only have one large association with paid officers we should be able to work the lot for a subscription of 5s. per year, and then there would be no excuse for any one not joining. Thanking you for your cordial coöperation,

I am, Sirs, yours faithfully,

Wigan, June 3rd, 1896. WM. BERRY.

An Unhappy Victim has omitted to enclose his name and address.

M.R.C.S.—The public notice is not to be commended.

A DISGRACEFUL ADVERTISEMENT.

THE *Umpire*, a Manchester paper, of May 17th, 1896, contains the following communication in its advertisement columns:—

"INTERESTING LETTER.

"I, Dr. Daniel Sutherland, Surgeon to the New Medical Hall, 243, Sauchiehall-street, Glasgow, hereby intimate to all whom it may concern that I have long studied and treated Confidential Complaints and weaknesses as a principal part of my Practice, both here and in Edinburgh, though never formerly made known by Advertisement, and it is possible this notice may be construed as a breach of professional etiquette; but I think it very pardonable when I consider the number of gentlemen constantly consulting me with their Constitutions injured, and Complaints aggravated, after being for months and years the dupes of Quacks and Druggists. I consider it a righteous necessity in the Public interest to advertise the fact that a Member of the Profession proper devotes his time to the study and treatment of these special Complaints. Gentlemen are therefore inexcusable if they fall into the hands of empirical pretenders. I make free to assure gentlemen entrusting me with their confidence that they may rely upon the highest professional honour, and skilled, conscientious treatment whether they visit me at 243, Sauchiehall-street, Glasgow, or communicate with me by letter, which will have my immediate attention.

"I am, faithfully,

"DANIEL SUTHERLAND.

"Licentiate of the Royal College of Physicians, Licentiate of the Royal College of Surgeons; also of the Faculty of Physicians and Surgeons. For seven years Councillor and Trustee of the City of Edinburgh; and Manager of the Royal Maternity Hospital, Edinburgh; President of the Scottish Christians, Evidence Society; Medallist (Royal College of Surgeons) 1867; awarded Queen's Prize (Science of Chemistry, Kensington Museum, 1863; Public Honours (Royal College of Surgeons) 1869, &c., &c.

"Book free for six stamps on confidential complaints written by Dr. Sutherland as above."

A correspondent has sent us this extract, asking if the corporation to which Mr. Daniel Sutherland claims, beneath his signature, to belong, should not take notice of such a flagrant breach of etiquette. We cannot find any person of the name in the current Register, but a Mr. Daniel Sutherland was struck off on May 20th, 1885. This may be the offender.

W. G. M.—We do not recommend individual practitioners.

"THE TREATMENT OF PLEURITIC EFFUSION."

To the Editors of THE LANCET.

SIRS,—Referring to the query of "Ubique" in THE LANCET of May 30th upon the above subject I venture to suggest that in the case mentioned it would be advisable to make an opening in the chest and provide for permanent drainage. I should put in my self-retaining tube figured in THE LANCET of the same date. The object for providing permanent drainage is to allow of the contact of the visceral and parietal pleural surfaces. This by the pressure of contact would at first tend to lessen the amount of fluid thrown out, and later by adhesion to stop its formation altogether, after which the tube would be no longer necessary. This, I think, would be an improvement upon the repeated tappings which have hitherto been necessary, and the lung would not suffer from constant pressure of fluid.

I am, Sirs, yours truly,

Cardiff, June 2nd, 1896. CORNELIUS A. GRIFFITHS, F.R.C.S.Eng.

MILITARY MEDICAL RECOLLECTION.

To the Editors of THE LANCET.

SIRS,—During active service in the Straits Settlements in 1875, when stationed at Qualla Jumpole, I knew a soldier in the 10th Regiment who was keen to kill a tiger. Having heard from a native that his buffalo had been killed the night previously he hurried to the river of the above name, and after waiting for some time he saw a tiger on the opposite side of the river approaching the dead buffalo he had partially devoured the night before. The sight was too much for "Tommy's" nerves, and having discarded his rifle and ammunition he fled back to camp, about two miles away, went straight to bed, and was successfully treated by me for a typical attack of typhoid fever.

I am, Sirs, yours truly,

Newcastle-on-Tyne, May 24th, 1896. J. HOYSTED.

H. A. B. will be very ill-advised to complain to the General Medical Council of anyone unless he is able to *prove* the subject of complaint.

"THYROID FEEDING."

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent "P. W." I have had experience in thyroid feeding and would suggest as follows: That the quantity given in the first week should not exceed one fresh gland in divided doses. Thus, one-quarter of a fresh gland may be given as a start on alternate mornings. It is preferable, in my opinion, to increase the dose by diminishing the intervals rather than by increasing the amount of each individual dose. One-quarter of a fresh gland will be found a full adult dose for a start at any rate. For myself, I would recommend unless there are special reasons to the contrary, that one or other of the various preparations of thyroid gland be used in preference to the fresh gland, for the reason that patients then regard it more as a medicine and are far less likely to overdose themselves. If, however, the fresh gland is for any reason decided upon it should be obtained from the butcher with the trachea still attached, and, for at any rate the first time, be examined and separated by the surgeon himself, otherwise strange mistakes are apt to arise and various other organs or glands to be substituted. Having obtained and cleaned the gland it may be administered either raw or very lightly cooked. In the former case it is sufficient to finely mince the amount of gland to be administered, season it if desired with pepper and salt, and give as a sandwich between bread and butter. In the latter case an easy way to prepare the gland is to fry it much in the same way as kidneys are cooked for breakfast but, of course, to a very much less degree. A very slight amount of cooking does not appreciably diminish the activity of the gland. That there is danger in excessive doses cannot for a moment be doubted by anyone who has once seen a case. Thus a patient of mine, a woman aged forty years, stout but otherwise healthy (I hope shortly to publish an account of her case), contrary to explicit directions, started by taking an entire gland lightly cooked on three successive mornings, and, to quote her own words, "I had a fearful trembling inside, my knees trembled and I could scarcely stand, my hands shook, and I had a fearful headache the first thing in the morning which used to wake me in the night with the pain." She left them off, but again, about a fortnight later, without my previous knowledge, ate two small glands at once in the morning. They produced the same effect on the same day. She left off again but seventeen days later she commenced taking capsules, eight of them being equal to one whole gland. One capsule caused a feeling of faintness on the same day, the pulse being 64 and the temperature 95·2° F. I may perhaps mention that other patients who had not previously taken the raw gland have taken one or more capsules in the day without ill effects. Apologising for the length of this letter,

I am, Sirs, yours truly,

MURTAUGH HOUGHTON,

Late Resident Medical Officer, Manchester Consumption Hospital.

Ilford, May 25th, 1896.

ERRATUM.—The address of the Red Cross Germicide Co. is 61½, Fore-street, E.C., and not as stated in our New Invention notice of May 23rd. We are asked to state that the inhaler, which is the invention of Dr. Siemon, has been patented in England.

During the week marked copies of the following newspapers have been received:—*South Wales Daily News, Cromer Post, Bath Chronicle, Sussex Daily News, Leicester Post, Brighton Gazette, Northern Whig, Worcestershire Chronicle, Devon Gazette, Liverpool Daily Post, Bradford Observer, Epicure, Belfast News Letter, Eastern Morning News, Croydon Guardian, Bolton Chronicle, Yorkshire Post, Western Daily Mercury, Sheffield Daily Telegraph, Carlisle Express, Times of India, Birmingham Post, Liverpool Courier, Kingston News, Pioneer Mail, Mid-Surrey Gazette, Bristol Mercury, Builder, Preston Guardian, Leeds Mercury, Blackpool Gazette, Architect, Scotsman, Daily Chronicle, Lincolnshire Echo, Tit-Bits, Retford Times, Light, St. Mary's Hospital Gazette, Bradford Daily Telegraph, Formby Times, Reading Mercury, Local Government Chronicle, Weekly Free Press and Aberdeen Herald, Mining Journal, Hertfordshire Mercury, City Press, Nottingham Daily Guardian, Surrey Advertiser, Local Government Journal, Gloucestershire Chronicle, West Ham Herald, Dover Express, Coalville Times, Hemel Hempstead Gazette, Guernsey Standard, Worcester Echo, Evening Post (Jersey), Public Opinion, Rossendale Free Press, Kelso Mail, Civil and Military Gazette (Lahore), Dundee Advertiser, Thanet Guardian, Harwich Chronicle, Macclesfield Courier, North British Agriculturist, &c. &c.*

THE LANCET

SPECIAL SUPPLEMENT

IN SUPPORT OF THE

METROPOLITAN HOSPITAL SUNDAY FUND

Published in aid of the Appeal to be made on Sunday, June 14th, 1896.

THE HOSPITALS OF THE METROPOLIS AND THEIR CLAIMS ON THE PUBLIC.

ONCE more it becomes our duty to lay before the readers of THE LANCET and the general public, for whose beneficent consideration this Annual Special Supplement is as much prepared as it is for that of our customary professional audience, the claims of the Metropolitan Hospital Sunday Fund upon the sympathy and practical assistance of all London.

We have made this appeal for the Fund on ten previous years. Therefore, although we have approached the subject from different directions on different occasions, and have dwelt at length now on this and now on that phase in the history of hospital work in the metropolis, we feel that to many the subject has, perchance, become threadbare. It may even have lost its interest for them altogether through this familiarity, inasmuch as our main tale must always be the same. Vary the rendering of it how we will the gist of what has to be said in these Supplements is now what it has been on the previous occasions, and the following words will sum it up:—The hospitals of London do noble work; the amount done by them is out of all proportion to their incomes; the slender incomes, being derived mainly from fortuitous charity, are precarious and liable to fluctuations; London, the city of untold wealth, should be able to furnish not only adequate but regular hospital accommodation for its suffering poor; Hospital Sunday furnishes the inhabitants of the metropolis with a regular and annual opportunity of showing their appreciation of the splendid work done by these medical charities; therefore, Give, GIVE, GIVE.

We propose this year to ask our readers to consider the Metropolitan Hospital Sunday Fund in particular from the following points of view. The Fund is one of the most important sources of income that many of the London Hospitals possess. By the annual reccurrence of its benefits the good done by it is enormously enhanced, for the regularity of the donations adds to their value inasmuch as it imports a sadly wanted element of order into hospital finance. And we also submit that as the metropolis grows the Fund should grow with equal steps, constituting itself a kind of universal rate, given out of good will. More forcible appeals, and pleas more likely to attract the public compassion, could easily be put forward, but a mere perusal of the figures in the various tables will tell the tale of the merciful work done. We shall on this occasion confine consideration of the Fund to the limits just indicated, feeling that in this way unanswerable arguments will be supplied to all why the collection of 1896 should not be allowed to drop below the large sum collected in 1895.

THE PECUNIARY POSITION OF THE METROPOLITAN HOSPITALS.

The tables which are here incorporated show the statistics of hospital work in the metropolitan area during the year 1895, under the various heads of General Hospitals, Special Hospitals, Cottage Hospitals, Dispensaries, and Convalescent Homes. Of a great proportion of these institutions the same thing may be said—their income is not as large as their expenditure. In some, and these are the largest and best known, the disproportion is notable, regular, and increasing, while in others matters are not so dark in hue; but in all the life of the institution is carried on under a perpetual pecuniary stress. All the work of organisation and administration and all the work of ministering, alleviating, and healing, and all the work of teaching, are made wearisome by the dragging strain of poverty. Let us consider what this means. The labour that goes to the due organisation of a hospital is not light. When we see the same labour displayed in the management of a group of business houses or a few railway stations we give public praise to the men at the head of affairs and sometimes public honour. Yet in most of these cases the work is done in affluence and with the direct stimulus of greater wealth to be obtained in the future, while the work of the hospital official is done under the repression of a chill and apparently hopeless penury.

The stress of this poverty is more directly felt by the lay management of the hospitals, but the medical officers who are in many cases associated with the non-professional boards in the administrative work also fall beneath it—it not infrequently blights their efforts in behalf of their patients, while every medical school in London owns its cruel influence. Nor have we exhausted the disabilities under which hospital work is done beneath the eternal shadow of impending bankruptcy by pointing out how much the irksomeness is increased by the penury. Not only is the anxiety of the managers thereby enormously aggravated, but they are driven to expensive courses, which in their turn lead to still greater depletion of the exchequer. For what is more expensive than being poor and having a precarious source of income? It is universally allowed that uncertainty of income leads to irregular expenditure or rather that the expenditure of such incomes is apt to be regular enough in that it will be maintained steadily at the

Digitized by Google

rate warranted by the highest annual receipts: the irregularity is manifested in the proportion of the sums spent to the income in bad years. This is so well recognised that in certain classes of the community whose earnings are capricious a condition of general indebtedness to their fellow men is practically condoned which would be considered utterly discreditable to persons earning their livelihood in more methodical callings. It is also elementary knowledge that debt leads to debt and so prevents retrenchment. All schemes for economy that are intended to bear practical fruit pre-suppose in those who enter upon them more than an absolute freedom from debt; they include the possession from some source or other of a surplus wherewith to buy in the cheap market that is open to ready money and to carry out alterations—costly, perhaps, at first, but bound to be economical in the end. In such a scheme not only must all arrears be wiped out by payment or arrangement, but facilities for trading at a greater advantage in the future must be obtained.

The pecuniary position of our hospitals should be regarded in the same way. The counsel of perfection is that a sum of money should be obtained which would place all the institutions upon a sound working basis by freeing them from debt, and which should also be large enough to endow them to the extent which experience shows to be that by which their average annual income is disproportionate to their necessary annual expenditure. The Metropolitan Hospital Sunday Fund bears a certain relation to such a perfect and perfectly Utopian scheme. It is a source of regular income representing about a million of capital. It is a stop-gap, it is a makeshift, it is a jury-mast, but by its aid work goes on that would otherwise cease and the ship of medical charity is enabled to persevere on its storm-ridden course.

THE PROGRESS OF THE METROPOLITAN HOSPITAL SUNDAY FUND.

The Metropolitan Hospital Sunday Fund has apparently settled down to contribute a certain sum annually to the expenses of the metropolitan hospitals—i.e., £40,000 inclusive of donations. The following figures show the progress of the Fund, and some of the reasons accounting for the fluctuations are appended, the donations being separated off from the totals:—

Progress of the Hospital Sunday Fund.

Year.	Totals.	Donations.	Year.	Totals.	Donations.
1873	£27,700	£1844	1885	£34,320	[illegible]
1874	29,936	1505	1886	40,399	[illegible]
1875	26,396	1424	1887	40,607	[illegible]
1876	27,042	1339	1888	40,379	[illegible]

* We reproduce the term "General Hospitals" as employed by the Council of the Metropolitan Hospital Sunday Fund.

[5] Including legacy of £1003 14s. from the executors of the late Thomas Crouch, Esq.

[6] In 1891 donations of £5000 from the late Duke of Cleveland, K.G., and £1000 from Sir Savile Crossley, Bart., were received.

[7] In 1892 Sir Savile Crossley, Bart., gave a further £1000; and a legacy of £105 was paid by the executors of the late Dr. H. E. Pitt of Brighton.

[8] In 1893 Sir Savile Crossley, Bart., gave a further donation of £1000.

[9] In 1894 a legacy of £5000 (less duty) was paid by the executors of the late W. J. Whitaker, Esq.; and Sir Savile Crossley, Bart., gave a further donation of £1000.

[10] In 1895 Messrs. Barnato and Friends gave a donation of £1000; £3400 was received from the Stock Exchange through Messrs. Price, Vaughan and Co., and Messrs. Burdett and Harris; Lord Iveagh gave a donation of £1000; Sir Savile Crossley, Bart., gave a further donation of £1000; and Mr. J. B. Robinson gave £1000.

From these figures it will be seen that twelve years ago the Fund made a sudden leap to the point which it was to maintain for the next decade. In 1884, owing to a magnificent donation of £4500 from the managers of the International Health Exhibition, the sum received was advanced from £33,935 in 1883 to £39,329. Falling somewhat the next year, it was righted again by donations and has since

Digitized by Google

mained at an average figure of a little over £40,000. 1 1895 the fund took an enormous upward leap owing to the enerosity of the Stock Exchange and of a group of financiers eaded by Mr. Barnato. £13,000 was obtained from a few dividuals, Mr. H. C. Burdett, whose personal exertions ere responsible for this splendid result, being the channel rough whom this munificence reached the fund. Consquently the total reached over £60,000, being £15,000 in cess of the previous highest collection. It will be this year e earnest endeavour of all to spare no pains to prevent 1885. The increase of last year being due to individual benevolence, not to receipts from general offertories, cannot be counted upon, and it will behove all to work as if no such fortunate increment were again likely to occur. Secondly, there have been quite recently urgent appeals made on behalf of a few hospitals, and these appeals have been generously answered. Many persons having responded to the special calls will feel themselves quit of their liability towards medical charities for this year, so that the field from which the harvest is to be reaped will be found smaller if not less

ck-sliding. The executive of the Fund cannot be blind to e factors that will be working against them in their tempts to keep the receipts at the now high level. we glance back at the figures of eleven and relve years ago we see that the point of £40,000 was ached practically in 1884, almost exactly the same m being contributed as was contributed nine years ter—viz., in 1893—but this inflation was succeeded by little collapse, the receipts falling again to £34,320 in fertile. These are the chief two reasons why there must be no grave disappointment if the sum of £60,000 be not reached this year. Nor must there be any discouragement of future effort, and one more glance at the figures in illustration of the progress of the Fund will show why. When, twelve years ago, the Fund quite unexpectedly received a large augmentation a drop took place the next year from the high level reached; but this drop was merely the recoil precluding the forward spring, for in the following year—viz.,

Digitized by Google

886—the sum of £40,000 was for the first time reached, at which figure the receipts have since been maintained.

Year by year the admirable and eloquent appeals of the London clergy of all denominations are directed to the raising of this money. Year after year their appeals make clear to their congregations that in their opinion the claim of the hospitals upon the public is imperative and one to which no professingly religious person can close his or her ears. And they speak from knowledge. The figures we place before our readers to-day constitute in themselves knowledge, but most of our metropolitan clergy have a deeper, closer intimacy with the working of the medical charities of London than can be gained by the study of a wilderness of figures. They not only prepare themselves to urge the claim of the Fund by obtaining every information even to the smallest details with regard to the general and medical work of the hospitals, but, ungrudging of the draft upon their already over-occupied time, they personally visit the institutions in their neighbourhood and see for themselves the work that is done in them. The advocates of the Metropolitan Hospital Sunday Fund from the London pulpits are fitted in every way for their task. They know how good the cause is for which they speak. But in spite of all this year after year—in spite of the excellence of the case to be pleaded and the sympathetic skill of the pleaders—the sum subscribed remains approximately the same. It is true that last year a sudden spurt was taken and that the fund rose by nearly one half, viz., to upwards of £60,000. It should not be allowed to go down again, but, having regard to the source of the sudden influx of funds, we are bound to admit that we can hardly anticipate that the larger sum will be reached—we can only hope. For years certain congregations have made up between them a certain sum, and we cannot pretend to see any reason why they should this year elect to contribute more. They may, nay, we hope will, and we propose to furnish them in this Supplement with two main reasons why they should.

The first of these reasons is the absolute necessity of the various medical charities of the metropolis for a regular income. The second is the fact that the Fund performs many of the functions of a central board for the management of the hospitals of London, and that the formation of such a board is very generally considered to be the first step towards the solution of the immense financial problems that vex the souls of the managers of the hospitals. There are many other reasons which will appear to most people, and not unnaturally, more cogent. The cause of the sick is one that will seem to demand more stirring language, and the arguments founded on humanity and blessed charity will suggest themselves as a more suitable way of appealing for support to the Fund than our more practical if less sentimental request that subscriptions should be given to enable the management of the hospitals to do their good work in a more business-like manner. Need we say that we are fully aware of the claims of the suffering poor; that neither the bitterness of their sorrows nor the sanctity of all endeavour to alleviate them escapes us? But we credit our readers with similar knowledge and similar sentiments. We simply design to furnish information to prove that the support of the Metropolitan Hospital Sunday Fund which would be dictated by loving-kindness is also most clearly indicated by common sense and common thrift.

THE VOLUNTARY SYSTEM.

It will be seen that the two reasons which we have just given why the claims of the Metropolitan Hospital Sunday Fund should receive the deliberate as well as the generous attention of the public can only be advanced if we presuppose that the existent system of support by voluntary contributions is the right one. It is the system of which we are all exceedingly proud. The spontaneity of the large annual gifts and bequests to our hospitals stands out pre-eminent in a not unselfish age as a grand testimony to the right-thinking generosity of the people at large, as a proof not to be gainsaid that the sympathy of the rich with the poor and of the whole with the sick is not merely of the lip, but proceeds from the heart also. Yet it would be wrong to bolster up such a system, however morally splendid, if it were found to be unworkable in a practical world.

Most of the hospitals are practically at their wit's end for money. Now it may be asserted: If so, the voluntary system must have broken down. The endowed charities must have lost or misspent their endowments, and they, together with the unendowed which have ceased to justify their existence in the eyes of the charitable, must come upon the rates. We do not think so. This is not the place to discuss the problems of State-supported hospitals and the need for a hospital board and no attempt will be made to do so. But a few words more may be said to show that in the opinion of those who know the voluntary system is the best and that in many directions the Metropolitan Hospital Sunday Fund exactly fills the gaps which even those proudest of it feel to exist in that system.

In the year 1890 the House of Lords appointed a Special Committee to investigate the whole subject of hospital accommodation in the metropolis, and that Committee, after deliberation which extended over two years, during which it received the assistance of a large number of highly competent witnesses versed in the various branches of the subject, produced a report. Although dealing with a great number of topics this report was mainly directed towards proving how greatly the work of the hospitals would be expedited, how enormously it would be advanced, by improved organisation, by a knitting together, in fact, of all the institutions into one coöperative whole. In accordance with this view the Committee made a recommendation that a Central Hospital Board should be formed and should be empowered to receive and publish hospital accounts, to advise upon new schemes, and to act generally as the authorised representatives of the public in the way of observing and appreciating and criticising hospital management and work. This proposal, notwithstanding the high authority by which it was recommended, has at present borne no fruit. Yet there is, in fact, no other thing possible if we still continue to employ the voluntary system. State aid, which is looked upon by many who would willingly take another view as the only remedy that the future leaves us to expect, would be fraught with many grave evils. It is the boast of our country that her hospitals are supported by voluntary contributions and are consequently free from the meshes of officialism. No man can obtain appointments at our hospitals in return for services rendered other than medical; the influence of politics is unfelt in our treatment of pneumonia; and red-tape is not a ligature that is employed in our wards. Yet inasmuch as many of our hospitals are on the verge of bankruptcy, their efficiency being seriously impaired by their poverty, the voluntary system must be held to have to some extent broken down. The demands of the sick have increased and the sources of revenue have decreased. The irregularity with which the impulse to give must necessarily act deprives the voluntary tribute of half its value. The voluntary principal is an admirable one, but it is jealous of system and prefers to act locally, impulsively, and irregularly. If certain much-needed qualities could be introduced into voluntary hospitals, if they could be brought to regard each other as coöperating for charitable ends not merely competing with each other for public subscriptions, if they could be brought to realise certain common principles of administration, a new era of prosperity might be assured to them. In almost these identical words we have recently summed up certain phases in the career of the metropolitan hospitals, and said that for these ills one panacea has been proposed—the creation of a Central Hospital Board.

THE FUND AS AN ORGANISING BODY.

Now it is precisely as an economising agency that the Fund has achieved its greatest success. At present there is but little prospect of the creation of any such central board, but the Council of the Metropolitan Hospital Sunday Fund has been in a position to accomplish much by way of suggestion and criticism to advance the interests of coöperation among the various charities. Nor is this all. The Council, has exercised a gentle but by no means ineffective supervision over hospital expenditure, and by comparison and scrutiny enforces the doctrine that every pound of revenue must be represented by its equivalent in the form of service or of necessaries supplied to the objects of the charity. In this way it accomplishes what no private benefactor could do were he never so assiduous to the ungracious task of criticism. The Council speaks with the authority of numbers and is comparatively free from the suspicion of partiality in its strictures. In this way it effects what has never before been attempted, and in a very considerable measure it succeeds in a task in which success, though of vast importance, is singularly difficult of attainment. Its contributions thus have a double value. They aid in the support of the assisted institutions and they contribute very materially to the economy of the whole revenues from whatever source derived.

A FARTHING RATE.

There remains now but one thing for us to do—to plore the benevolent public to remember that as the size the metropolis increases, so the Fund should grow, if the ntributions are to be taken to represent a voluntary rate, meet the wants of our sick poor.

The recent census of London has shown that in the riod between 1891 and 1896 the metropolis increased in pulation to the extent of 221,000 souls. This is a number ual to the entire population of a very large provincial town. o assist the appreciation of the figures, we have prepared agrams showing by proportionate areas the proportionate agnitudes of Newcastle-upon-Tyne and New London, by hich last expression we intend to signify the addition which as been made to the population of the County Council's ondon within the past five years.

FIG. 1.

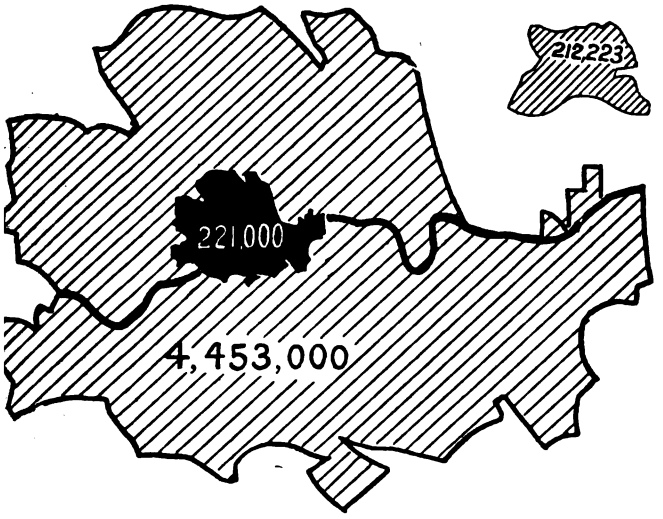

FIG. 2.

IG. 1.—The County Council's London: the dark patch represents "New London."
FIG. 2.—Newcastle-on-Tyne.

This great development has not been accompanied by any rresponding growth in our greatest charity—the Metro-olitan Hospital Sunday Fund. In point of fact, the annual llection shows no growth at all. From time to time the nount placed at the disposal of the Council of the Fund ceives a welcome augmentation from the bounty of some rivate individual, but the sum collected in the churches as actually less in 1893 than in 1884, and had it not been r private munificence the Fund would have been sadly ippled last year. It is worth while to make the attempt realise what the significance of this may be.

And first let us take the collection at its best and pportion it over the population of the metropolis. In 1890 ne amount collected by offertory was nearly £39,000 and the opulation nearly 4,200,000, so that the average contri-ution of every individual would amount to something *ss than one farthing*. For the purpose of this estimate is assumed that only the County Council's London is nterested in the hospitals of the metropolis. But that very far from the fact. Outside the official boundary es a densely populated zone inhabited by Londoners, lthough nominally appertaining to the adjacent rural istricts, and to this area are extended in no small measure he benefits of the metropolitat hospital system. Were the opulation of Greater London taken into account for the urposes of our present estimate the modest farthing would hrink considerably. Let it, however, suffice to assume, ithout refining upon the figures, that Londoners are pre-ared to support this great charitable work to the extent of n annual subscription of one farthing a head.

This is by no means an unfair way of estimating the result, or although it is quite true that a charge of whatever kind listributed evenly over the entire population in proportion to he number of heads would bear very unduly upon the poor, et if, on the other hand, the benefits conferred by hospitals re considered, it will, of course, be found that these are in preponderating measure realised by the most numerous and east wealthy classes of the community The families, including children, of the poor are no less dependent than the families of the rich upon medical attendance, and to a very large extent in the case of poor people this necessity is supplied by hospitals. An estimate of population, therefore, affords the best means of realising how the benefits of the hospital service are distributed, for no class is excluded from these benefits; and when it is realised that the return made in the form of the Metropolitan Hospital Sunday Fund works out at something less than one farthing a head it will, we think, be freely admitted that there is good reason for regarding it, not only as inadequate to the needs of the hospitals, but also as unworthy of the community which contributes it.

THE SMALL CONTRIBUTOR.

This is a view of the facts which should commend itself especially to persons of moderate or restricted means. To such the Metropolitan Hospital Sunday Fund affords a peculiarly fit opportunity of tendering support to the medical charities of London. A small subscription given in this way possesses both actually and sentimentally a value that it could not otherwise have. It is no small thing that the widow contributing her mite upon this occasion should be able to feel that it becomes part and parcel of a Fund large enough to form an indispensable part of the charitable revenues of this great city and yet drawn almost entirely from sources such as her own benevolence has opened up. Thousands of persons in London are so situated. The subscription list with its regulation guinea is not for them, and were it not for the recurrence of the Fund collections they would stand quite aloof, wishing well to their suffering neighbours, but being powerless to promote their well-being in any way.

It is from this class that the revenues of the Metropolitan Hospital Sunday Fund are chiefly drawn. Large contributions are the exception and rightly so. For although the Fund has claims upon the rich it has especial claims upon the poor, and the comparatively poor are so much the most numerous class that they preponderate by reason of their numbers, and must continue so to do as long as the Fund continues to command the general confidence and support of the people at large. It would, indeed, be a sad day when the struggling many withdrew from the support of this charity and left it to be carried on by the opulent few. The resources of the opulent are much more restricted than those of their poorer neighbours, and it is upon the sympathy of the many that any great undertaking must be built which, like that advocated to-day, requires ample and continuous pecuniary support. The days of "princely" munificence are past, the new word has not yet been coined, but the new order has appeared, and in due time we shall recognise by a suitable word that *the munificence of the masses* has in these later times replaced that of princes and has become the mainstay of all spontaneous movements upon a large scale.

THE GROWTH OF THE FUND AND THE GROWTH OF THE CITY.

The Hospital Sunday Fund, therefore, must as the first condition of success commend itself to the conscience and approval of the great public, and its success in the past affords strong evidence that it has not failed in this respect. But this is precisely the point at which it becomes difficult to understand why during the past few years there has been no regular increase in the annual collection. The growth above depicted imports growth of the need supplied, growth of the contributing community, and growth of the available resources. The enormous fact brought to our sight by these diagrams needs no insisting upon. In five years a town as large as Newcastle-on-Tyne has been added to London. In compensation for the additional responsibility that this increase of population has laid upon our hospitals proportionate subscriptions should have been added, and should continue to be added to the Fund. The £60,000 that was reached last year by a bound should now be easily forthcoming as a regular subsidy. But we cannot count upon this. We can hope for it and work for it, and even expect it, because of the justice of the expectation, but it may not arrive. The total subscriptions may recede again to £40,000, and lest it should so happen, let us consider the circumstances to which may be attributable the deficient interest in the objects of the charity.

One reason, and only one, affords a possible explanation.

Digitized by Google

The churches we know have not wearied in any measure of this good work, but that the public may to some extent lose sight of it is credible. The very fact that the collection comes round with the regularity of an anniversary makes it easy for it to slip into a matter of routine, and as such to lose more or less of the human interest in which it takes its rise. If we are right in this surmise then the remedy for the shortcoming which we have at present to deplore must be sought in bringing home with force the forgotten facts concerning the medical needs of London.

This is a task which devolves mainly upon the clergy of various denominations, and they will certainly not be wanting in its performance. Whether it may be possible for them to increase the urgency of their appeals is a question upon which we do not presume to offer an opinion. If it be so, then we doubt not that they will fill the position, feeling with us that the object is worthy of their best and greatest efforts. The great public needs to be aroused both to an apprehension of the facts and also to a sense of responsibility

were relieved, 57,796 were cured, and 6730 died. But, as we have implied, the sense of personal interest is a less worthy, and in this case we are convinced that it is a less influential, motive than the sense of sympathy with the sufferers, for whom our hospitals afford the only available refuge. That tale of 103,249 in-patients speaks of untold suffering and absolutely invaluable relief; the 6730 deaths mean what no words can express in the way of softening the death-bed sorrows of the poor. But what these figures do not in any way pourtray is the suffering borne without the aid of skilled attendance and the elaborate appliances which the hospitals afford. Great as is the work actually done it leaves much unaccomplished and even unattempted by reason of the starved condition of the institutions. This is the voiceless grief, which more than any words, appeals to those who know the facts. This, if it could be painted in such wise as to be understanded of the people, would evoke a response such as has never yet been made to the advocacy of the Metropolitan Hospital

for the support of the medical charities of London upon an adequate scale, and we venture, therefore, to submit a few considerations bearing on these points.

THINGS THAT THE PUBLIC SHOULD READ, MARK, AND LEARN.

The great public comprises a very wide range of classes and conditions of men, but none on whom the many-sided charity which comes to-day to the fore has not pressing claims. Of that largest class of all, distinguished neither by poverty nor riches, we have already spoken. To them the hospital is not simply a form of charity, but in a real and even an emphatic sense a resource, since in many emergencies they must and do resort to it for the relief of their own necessities. From this point of view the record of work done in the London hospitals during the past year constitutes an eloquent appeal. We take the following illustrative figures from the returns furnished to us by the hospitals:—In-patients treated 103,249, of whom 33,889

Sunday Fund. But if the materials for such an appeal are lacking experience is not wanting from which they could be supplied. Among the working classes there are but few persons of adult age who cannot tell of instances of cruel suffering patiently, and often heroically, borne in poverty and distressing circumstances which might have been greatly relieved if hospital accommodation had been available for its treatment. Such instances give point, and even poignancy, to the reflection that great as is the good work done by the hospitals of the metropolis it is unequal to the vastly greater requirements of growing London. And yet the Metropolitan Hospital Sunday Fund, as represented by offertories, does not grow.

THE IMPARTIAL WORK OF THE FUND.

No class of the community is beyond the reach of some claim on the part of the Metropolitan Hospital Sunday Fund. If the poor by special knowledge of the ways to which it administers have special reason to value

Digitized by Google

its ministrations, the well-to-do, upon the other hand, are under a peculiar obligation to contribute to its support. It must never be forgotten that rich as well as poor appear as patients in the hospital wards. In this respect no distinction is drawn between one class and another when it is a question of accident or unforeseen emergency. The club man struck down by a cab in Piccadilly is equally welcome with the labourer crushed by a crane at the London Docks, and to the one no less than to the other the prompt aid which the hospitals afford is at such a conjuncture a question of life or death. Nor should it be forgotten in this connexion that to rich and poor alike the benefit accrues of the great schools of medicine which find in the hospitals of the metropolis the unsurpassed instruments of clinical instruction. It is, therefore, not upon a *different footing* that the appeal is rested which is to-day made to the wealthier classes, as well as to the preponderating number of the poorer classes. The difference is rather a difference of knowledge and experience. To the poor the problem is familiar, its urgency and its extent are well known and easily understood, whereas the resources which are available for dealing with it are much less perfectly apprehended. The rich may have some difficulty in appreciating with what crushing weight the burden of sickness bears upon people of narrow means, but at least they know that a contribution of £40,000 a year is a mere bagatelle when drawn from the length and breadth of London, and that it does not in any sense represent what the churches of the metropolis would accomplish under a genuine impulse of the enthusiasm of humanity.

It may indeed be said that wealthy Londoners are accustomed to contribute largely to the sustentation funds of the various hospitals, and that their contributions to this particular fund amount only to a small part of their whole benefactions flowing in these channels. And this is perfectly true. By financial and personal help, as by service upon committees and the like, the laymen of London take a noble part in hospital work. And we should be sorry indeed to say a word in disparagement of that personal interest in the well-being of some particular institution which is happily so widely diffused throughout English society. But this notwithstanding, the Metropolitan Hospital Sunday Fund has very special claims to the consideration even of those whose interests are most deeply involved in behalf of this, that, or the other institution. None more than these persons feel the painful sense of inability to respond to all the deserving claims that come before them, and none more than they yearn for larger means of help or the power by a sound economy to make such means as they command go farther and effect more good. The Metropolitan Hospital Sunday Fund exactly meets such a want.

Give, Give, Give.

And that is our appeal on behalf of the Metropolitan Hospital Sunday Fund for this year.

The rich should give out of their bounty, and not only because they are rich, but because they are directly benefited by the hospitals.

The poor should give out of their poverty, and they need no reminding what the hospital means to them when they are sick.

To the benevolent-minded no scheme can commend itself as more worthy of their aid than a fund to benefit their suffering and poorer brethren.

In the eyes of the practical and inquiring, no less than in those of the benevolent, the Fund must find favour, for it represents order in the distribution of charity, while it strengthens the voluntary system of hospital support, of which we are all properly proud.

To all orders of mind, to all social grades, and to all creed alike the Metropolitan Hospital Sunday Fund must appear as a noble charity, splendidly directed, economically managed, justly administered, practical, and humane. Therefore, to all but one word remains to say—Give, GIVE, GIVE.

Audited and found correct, this 22nd day of November, 1895.

(Signed) W. H. PANNELL & Co., *Chartered Accountants*, Basinghall-street, E.C.

*** In the preparation of the voluminous statistics of hospital work which have been here digested and exhibited in collected form (and which have been specially supplied to us in response to our applications, and are quite independent of any returns made to the Metropolitan Hospital Sunday Fund Committee) we have been greatly indebted to a large number of secretaries and other officers of the various medical charities of the metropolis. To them we desire, as on many previous occasions, to tender our sincere thanks.—ED. L.

The Croonian Lectures:

A CONTRIBUTION TO THE STUDY OF THE BLOOD AND THE CIRCULATION.

Delivered before the Royal College of Physicians of London,

BY GEORGE OLIVER, M.D., F.R.C.P. LOND.

LECTURE II.[1]

Delivered on June 4th, 1896.

ANIMAL EXTRACTS.

MR. PRESIDENT AND GENTLEMEN,—Some preliminary observations with the arteriometer having afforded me evidence that certain of the animal extracts (such as those of the suprarenal bodies, the thyroid gland, and the brain-tissue) when administered to healthy subjects by the mouth modify the calibre of the arteries, I was led to avail myself of the resources of the laboratory in order to determine the matter. I had been particularly struck with the constrictive effect of suprarenal extract and the dilating influence of thyroid extract on the radial calibre. In this investigation I had the invaluable coöperation of Professor Schäfer.[2] The extracts employed were those derived from the suprarenal bodies, the thyroid gland, the spleen, and the pituitary body. They were prepared for the most part with water (in the earlier part of the inquiry with glycerine) and either from the fresh glands or from glands dried rapidly at 38° C. The suprarenal extract is the only one of the series which has been investigated in any detail; but as the effects on the blood pressure have been determined in a preliminary way in the others I will refer to them before describing more particularly the physiological action of the suprarenal extract.

We found that the intravenous injection of thyroid extract produced a marked fall in the blood pressure, although the beats of the heart remained the same in frequency and strength. Therefore, it may be inferred that the lowering of the blood pressure was the direct result of increase in the calibre of the arteries, an inference which derives support from the observation which had previously been made with the arteriometer. This direct action on the vascular system is, however, probably only one of the various physiological relations borne by the gland to the organism; but it may be connected with important functions, such, for instance, as the heat-regulating function. In support of this position it may be mentioned that animals on which thyroidectomy has been performed and the subjects of myxœdema are particularly prone to suffer from subnormal temperatures. Furthermore, it has been demonstrated by Lorrain Smith that thyroidectomised animals react to change of temperature with abnormal rapidity, as indicated by the shortening of the time required for the augmented emission of carbonic acid which follows exposure to a low temperature.[3] It is, therefore, not unlikely that in myxœdema the withdrawal of the internal secretion of the thyroid which acts directly in dilating the vascular system may in a measure account for the reduction of the temperature so frequently observed and for the development of other signs of lowered vitality. We are not, however, prepared to assert that this effect of thyroid extract on the arterial wall is specific, for we have found that a similar result is obtained by the intravenous injection of decoctions of some other glandular organs—i.e., the parotid and sub-maxillary glands of the dog.

We have observed that the intravenous injection of spleen extract produces a somewhat characteristic curve of blood pressure consisting of a preliminary fall succeeded by a gradual rise, and by as gradual a return to the normal. The significance of this curve has not been as yet investigated. On the other hand, the pituitary and suprarenal extracts were found to possess the property of exciting powerful contraction of the arteries and of raising the blood pressure to a very marked degree. The action of both these extracts on the vascular system is not only different in character from that of the thyroid and spleen extracts, but is more energetic. Moreover, though they possess the common property of constricting the arteries, they themselves present certain points which differentiate the one from the other, such as the following: (1) The pituitary extract, though the effect of it is well marked, is less active than the suprarenal, for a much larger dose of it is required to produce the same rise of blood pressure; (2) the pituitary curve of blood pressure rises more slowly and is maintained for a longer time than the suprarenal curve; the active principle is, therefore, less readily eliminated from the blood than that of the suprarenal; (3) the pituitary extract also differs from the suprarenal when injected into a dog with intact vagi in failing to inhibit the heart's action; and (4) the pituitary does not possess the characteristic action of suprarenal extract in accelerating the heart's action in an animal with cut vagi or when atropinised; on the other hand, it then generally diminishes slightly the frequency and at the same time augments the beats of the auricle and ventricle.

The action of the two extracts coincides, however, in the following respects: (1) the rise of blood pressure is the combined effect of (*a*) contraction of the arterioles and (*b*) augmentation of the heart's beats; (2) the effect on the heart and the arteries is direct or peripheral, for it occurs equally well with the cord cut or the bulb destroyed, and when added to Ringer's circulating fluid and perfused through the vascular system of the frog with the nervous centres destroyed the flow of fluid is greatly diminished; and (3) boiling for a short time does not destroy the activity of the extracts. The action of suprarenal extract on the circulatory system may be divided into that which affects the heart and that which affects the arteries.

(*a*) *The effects on the heart* have been derived from observation of the isolated frog-ventricle and of the mammalian heart, the former being brought under the influence of the extract by perfusion in Ringer's circulating fluid and the latter by intravenous injection. The heart of the common frog was tied in the usual manner to a perfusion cannula and fed through this with the circulating fluid in the apparatus elsewhere described.[4] It was observed that when the ventricle failed to beat the suprarenal circulating fluid invariably produced spontaneous contraction; that when the contractions only recurred after long intervals it accelerated and regulated the rhythm; that when successive groups of contractions (Luciani's groups) appeared with varying asystolic intervals it increased the number of the contractions in each group until the rhythm became uninterrupted; and that when the ventricle was beating feebly it tended to increase the strength of the contractions. Furthermore, it was found that with a certain proportion of the extract the time of the pause between two successive contractions is markedly reduced, and with a further proportion of it the pause may be entirely obliterated and the beats succeed one another without any apparent interval. A further stage in this action which obtains with solutions of still greater strength (1 per cent. and upwards) is that the beats begin to run the one into the other, one contraction succeeding another before the completion of the preceding diastole. The result is that the dilatation is imperfect and may ultimately be almost entirely or quite abolished, so that eventually the heart stops in systole. If now, however, the suprarenal circulating fluid is washed away with the ordinary circulating fluid the heart may completely recover and the same experiment may be repeated several times in the same fashion. The effects of the extract on the mammalian heart were observed in dogs, cats, and rabbits. The contraction of the auricle and ventricle were separately recorded by means of the apparatus described in the paper which has appeared in the *Journal of Physiology*.[5] The effects produced were found to be entirely different, according as the vagi are intact or are cut or paralysed by atropine. When the vagi are uncut the most striking effect is to slow or even to entirely abolish for a time the contraction of the auricles. Their action, after the period of latency necessary for the passage of the solution to the heart, is rapidly stopped in diastole; in other words, they are powerfully inhibited. But usually this inhibition of the auricles is preceded by a short period of augmentation.

[1] Lecture I. was delivered on June 2nd and published in THE LANCET of June 6th, and Lectures III. and IV. were delivered on June 9th and 11th respectively.

[2] The results of this research have appeared in the Journal of Physiology, vol. xvi., 1894, and vol. xviii., 1895.

Digitized by Google

When the auricles are inhibited the ventricle continues to beat with an independent slow rhythm. On the other hand, when the vagi are cut, or when the animal is atropinised, the effect of the extract on the heart is exactly reversed—namely, the contractions of the auricle and ventricle are markedly augmented and accelerated. Therefore, it is obvious that the inhibitory effect of the extract is not derived from a direct action upon the heart. It would seem, therefore, from these observations that suprarenal extract exerts a powerfully stimulant action on the heart.

(*b*) *The effects on the arteries.*—That contraction of the arteries and arterioles is a prominent effect of the extract has been abundantly demonstrated by the application of Mosso's plethysmograph to the limbs and of Roy's oncometer to the spleen and kidney, by perfusing Ringer's circulating fluid containing the extract through the arterial system of the frog after destruction of the nervous system and noting the result of the passage of the extract in altering the rate of flow through the bloodvessels, and by direct ocular evidence of the large and small bloodvessels. This contraction is so great as to produce an enormous diminution in the volume of an organ such as a limb or the spleen or the kidney, and in the case of the frog with its nervous system destroyed almost complete cessation of the flow of circulating fluid through the arterioles. Consequently the blood pressure rises very considerably, even though concomitant vagus action causes a great diminution in the rate of the heart's action. Though this increase of the blood pressure is large while the vagi remain uncut, it becomes enormous—it may reach four or five times its original level—when they are cut or when their cardiac ends are paralysed by atropine; then the arterial pressure becomes so great as to passively expand the larger sized arteries until they are seen to swell almost to bursting and to be proportionately elongated. The arterial contraction and the consequent rise of blood pressure are so decided that the strongest stimulation of the depressor nerve does not inhibit the contraction and reduce the pressure. Contraction of the spleen took place invariably and to a far greater degree than obtained with the limbs.[6] Though we were unable to record any plethysmographic observations on the intestines it may be fairly assumed that the great rise of the blood pressure which invariably follows the injection of the extract is in all cases due very largely to the contraction of the arterioles of the splanchnic area. We have proved that this contraction is not indirectly produced through the vasomotor centre, but is an immediate effect on the muscular tissue of the smaller arteries in mammals, for it occurs equally well after destruction of the bulb or section of the cord, or, in the case of the arm, after severance of the brachial plexus, and in the frog with the brain and spinal cord completely destroyed. In this sketch a portion only of the ascertained facts, the effects of the extract on the organs of circulation can only find place. It may, however, be further stated that we ascertained that the active principle is contained entirely in the medulla of the gland, is absent from the organ in advanced Addison's disease, is dialysable, and is not destroyed by boiling for a short time, or by acids, or by peptic digestion, but may be destroyed by long boiling or by alkalies, and that it is not neurine or a salt of neurine, as was supposed by Cervello[7] and Marino-Zucco.[8] It has so far eluded isolation. Mr. Moore has pointed out that it is probably identical with a substance which was first described by Vulpian[9] as peculiar to the medulla of the suprarenals (its reactions not being afforded by any of the other glands), the solutions of which assume a rose-red colour on exposure to the air or to oxidising reagents.[10]

We have observed that the intravenous injection of digitalis and ergot produces quite insignificant effects on the heart and the arteries by the side of those obtained from the smallest dose of the extract which we have employed. We have, however, found one substance which furnishes an effect practically identical, and that is nicotine. This fact is of some interest, because Krukenberg in 1885 described a substance which he obtained from the suprarenal bodies having a chemical formula almost identical with that of pyridine,[11] and nicotine may be regarded as a pyridine derivative. The active principle of the adrenals is, however, not pyridine, for the observations of Lauder Brunton and Tunnicliffe[12] have shown that the physiological action of that body is quite different from that of the suprarenal extracts, but it is not improbable that it may eventually be shown to be an organic alkaloid the nucleus of which is pyridine. Perhaps the most interesting and important fact in regard to the active principle of the adrenals is the extreme minuteness of the dose that is necessary to produce the results just described, and in this respect it undoubtedly agrees with what is known in regard to the potency of nicotine. Our experiments have shown that so small a portion of the extract as is equivalent to 5½ milligrammes (0·0055 gramme) of the dried gland will induce the maximum effect on the heart and the arteries of a dog weighing 10 kilogrammes, or ½ milligramme for each kilogramme of body weight. How infinitesimally small, therefore, must be the proportion of the active principle injected in such a diminutive dose of the gland will be apparent when deductions are made for the cortex (¾ of the gland in weight), which we have proved to be devoid of physiological activity, and for the proteid and other material (⁹⁰⁄₁₀₀ of the dried gland) which are not dialysable. So that it follows that a maximal effect is produced by not more than fourteen-millionths of a gramme of the active adrenal material per kilogramme of body weight—an infinitesimal dose indeed.[13]

Finally, the evidence which the arteriometer has yielded bearing on the effect of adrenal treatment on the circulation in man may here be very briefly quoted. That evidence entirely coincides with the physiological facts. It has been repeatedly observed that when circulatory compensation was impaired, as in anæmia and in other asthenic conditions, to which reference was made in the first lecture, the exhibition of the adrenal preparation was followed in a few days by restoration of the postural radial measurements, and this observation has been repeatedly checked by the different effects produced by omitting the treatment and by resuming it. The accumulation of a large number of concurring observations in which small doses of the dried medulla of the gland[14] have been prescribed in various forms of vasomotor (splanchnic) inadequacy has led to the conviction that suprarenal treatment in such cases is a useful addition to our therapeutic resources, and that it should be applied rather from this wider view based on its physiological action than merely from the exclusive one suggested by Addison's disease.

The foregoing observations tend to show that the ductless glands furnish to the blood certain materials of great potency which are necessary for the purpose of modifying in various ways the circulatory mechanism. It can, therefore, no longer be said that the whole of that office should be allotted to the nervous system. Doubtless the master-tissue exerts the dominant influence, and internal secretion derived from the ductless glands is but a comparatively subordinate agent. Though subordinate, it is, however, a modifying agent of some importance to the nutrition of the tissues and the well-being of the organism—a fact which becomes pathologically patent enough whenever one of these glands becomes the seat of degeneration. Inasmuch, however, as observation has shown that the activity of the products they elaborate is not destroyed by the digestive act an avenue is thus provided for the operation of the remedial power of physiological medicine.

MASSAGE.

It is agreed by all authorities on massage that the circulation of blood through the manipulated tissues is accelerated and increased. This fact has, moreover, been clearly demonstrated experimentally on dogs and cats by Lauder Brunton and Tunnicliffe, who determined the amount of blood which issued from the efferent vein derived from the group of muscles manipulated, the observation having been made immediately before, during, and at various intervals after the application of the massage. These observers established the following conclusions:—"1. During the massage of muscles the flow of blood through them is increased. 2. Immediately after the cessation of

[6] In a paper on the Rhythmic Contractility of the Spleen, read before the Royal Society last January, Professor Schäfer and Mr. Moore showed that suprarenal extract caused an enormous contraction of the spleen followed by an increase of the rhythmic waves.

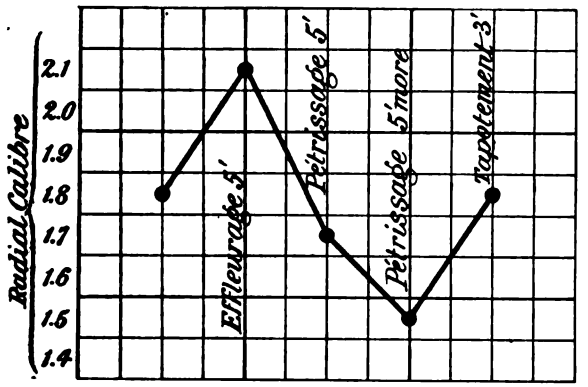
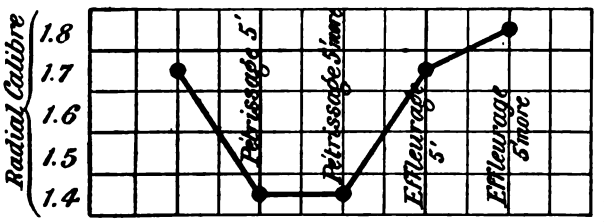
massage an accumulation of blood occurs in the massaged muscles; this is rapidly followed by an increased flow through the muscles. 3. The massage of a considerable muscular area causes first a slight rise in the general blood pressure; this is followed by a fall which in some cases amounts to one-fifth of the initial blood pressure.[15] The results of my observations in man coincide with these conclusions. The local effects on the radial pulse are easily learnt by applying the various forms of massage to the muscles of the forearm. Figs. 6 and 7 show that the lighter and superficial manipulations (such as stroking, effleurage) and vibratory movements or percussion (such as what is known as hacking, punctation, slapping, &c.) raise the radial blood pressure and calibre, and that the intermittent rolling and squeezing of the muscular tissue (pétrissage) reduce them. The immediate effect of all the forms of massage is to raise the blood pressure and to enlarge the calibre of the artery. This preliminary stage is maintained for some time while the more superficial and vibratory manipulations are being

FIG. 6.



Effects of different forms of massage on the radial calibre.

FIG. 7.

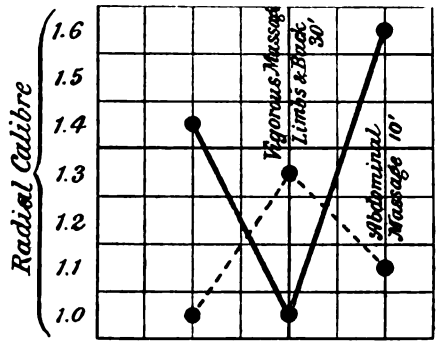


Effects of different forms of massage on the radial calibre.

employed, but it is very transitory indeed when that form of massage is applied which freely moves the muscular tissue and is quickly followed by a very decided and sharp reduction of the radial calibre.

From this it would seem probable that the first effect of massage in its various forms—and an effect which is, moreover, maintained throughout the application of the superficial and vibratory manipulations when limited in duration—is to induce vasomotor contraction in the terminal vessels, and thus to raise the blood pressure and the calibre in the intermediate arterial tubing between them and the heart. This may, therefore, be regarded as the vasomotor tonic aspect of massage, when that process assumes the forms of stroking, vibration, and percussion, which therefore raise arterial tension.[16] When, however, the muscular tissue is freely manipulated and rolled the vessels therein dilate, and the flow of blood through them is increased and accelerated by the rapid manipulations acting in the manner of a supplementary heart, and the blood pressure and calibre of the radial and other systemic arteries, being thus short circuited as it were, fall. This is the vasomotor relaxant effect of massage which reduces arterial tension. When the muscles of all the limbs are manipulated the radial calibre and pressure fall (see Fig. 8). There may be perceived a larger ictus after the manipulations, but it is unsafe to infer therefrom that the radial calibre is increased, for arteriometric measurement has shown that when the pulse tension is reduced the pulse-stroke generally feels larger, though the calibre of the vessel is actually diminished. How is this reduction brought about? The diversion of the blood to the capacious periphery located in the muscles is no doubt a leading cause of it. But there is some evidence that points to the conclusion that this may not be the sole cause. Figs. 8 and 9 illustrate this point.

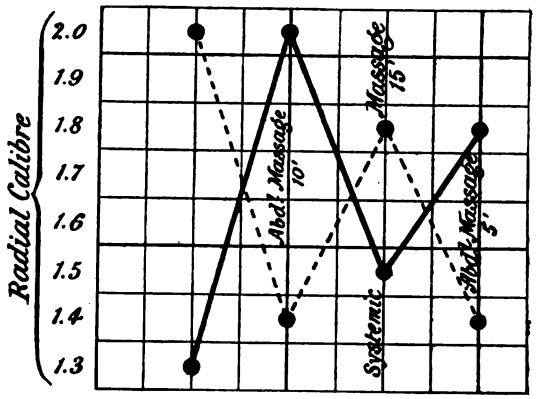
FIG. 8.



Effects of systemic and abdominal massage on the radial calibre. Male, aged thirty-nine years. General wasting. Recovered 1st. from rest, massage, and Swedish movements in three weeks.

It has been observed that when vigorous massage is applied to the limbs and the back for twenty or thirty minutes, the normal postural variations of the radial calibre and pressure are very apt to become—if they do not invariably become—reversed, so that they measure less in the sitting than they do in the recumbent posture, and when this happens it has been found that manipulation of the abdomen for eight or ten minutes restores the normal formula of the pulse. It would, therefore, seem probable

FIG. 9.



Effects of systemic and abdominal massage on the radial calibre. Male, aged twenty-five years. Neurasthenia.

that massage, when confined to the systemic muscles, disposes to the accumulation of blood within the capacious venous system of the abdomen. It will be observed that in Case 2 (Fig. 9), a neurasthenic subject, the normal postural radial measurements were reversed before the application of massage; that abdominal massage for ten minutes restored

[15] On the Effects of the Kneading of Muscles upon the Circulation Local and General. By T. Lauder Brunton, M.D. Edin., F.R.S., and F. W. Tunnicliffe, M.D. Lond. Journal of Physiology, vol. xvii., 1894. Klein also showed that kneading of the muscles of a rabbit's leg produced a fall of the blood pressure.—Skandinav. Archiv für Physiologie, Band i., p. 247, 1887. These observations have recently been confirmed by Reid Hunt, Journal of Physiology, vol. xviii., 1895, p. 389.

[16] Dr. W. Balfour eighty years ago wrote: "Percussion, instead of repelling, creates an afflux of nervous energy and sanguineous fluid to the part. Vessels in a state of atony are thereby roused to action and circulation is promoted."—Illustrations of the Power of Compression and Percussion in the Cure of Rheumatism, Gout, and Debility of the Extremities and in Promoting Health and Longevity, by Wm. Balfour M.D. Edin., 1816.

Digitized by Google

them; that the reversed postural formula was reproduced by massage of the systemic muscles; and that the normal measurements were once more restored by manipulation of the abdomen. In corroboration of the position that abdominal massage may raise the blood pressure there are also the observations of Glovetzky. This observer made a large number of experiments on men and dogs to show the effects of abdominal massage on the circulation. He found that the upper half of the body increased in weight after the *séance*, as shown by Mosso's balance, and plethysmographic measurements proved that during the sitting both the upper and lower extremities increased in volume, but returned to their normal size after the massage. The blood tension and the intra-cranial pressure invariably rose during the massage and the elevation lasted for a certain period afterwards.[17] While referring to abdominal massage it should, however, be remarked that though a short application of it may restore the normal contraction of the vessels supplied by the splanchnic nerves the continuance of it beyond a very limited period is apt to defeat the aim in view, for then it is not improbable either that the contractility of the vessels becomes exhausted and dilatation of them is thus favoured or the heart's action is lowered through reflex over-stimulation, so that it would seem to be best, as a rule, to apply massage to the abdomen in some of its vibratory forms and for a brief period only and after the general massage has been performed.

How far is massage comparable with exercise? It has been pointed out that in exercise—local and general—the volume of the limb is considerably increased from the afflux of blood, and probably also from the infiltration of watery fluid from the gorged vessels into the substance of the muscles. Volumetric observation of the arm has shown that massage when applied for a short time—e.g., for from seven to ten minutes—generally induces a slight diminution of the limb.[18] Therefore it would seem probable that any watery exudation that may flow from the blood during the manipulations is pressed forwards from the lymph spaces into the lymphatics. In the fourth lecture it will be shown there exists some evidence in favour of the view that in massage the blood does yield an effusion of fluid as in exercise, but that it is dispersed by the process as rapidly as it is exuded, and consequently the volume of the manipulated limb is not increased. This, then, is the only point in which it has been found that the local effects of massage differ from those of exercise.

The practical outcome of these observations, which probably coincide in the main with the teaching of general experience in regard to massage, seems to be the following. Massage should not be prescribed and performed in a mere perfunctory routine fashion, as is to be feared it too often is; but, like other therapeutic measures, it should be applied with due discrimination. The leading features of the circulation are the best indications for the selection of the kind of manipulations to be adopted, for the limitation of the time of their application, and for the distribution of them, whether mainly to the viscera or to the systemic muscles. When, for example, the vasotonic effects are sought for the manipulations should partake chiefly of the nature of vibration or percussion, and in those cases in which muscle-kneading is resorted to percussion should terminate the process. When, on the other hand, the aim is to reduce arterial tension and to relieve the ventricular effort the deep movements should be preferred throughout and should be applied only to the limbs and back, and the abdomen should not be manipulated.

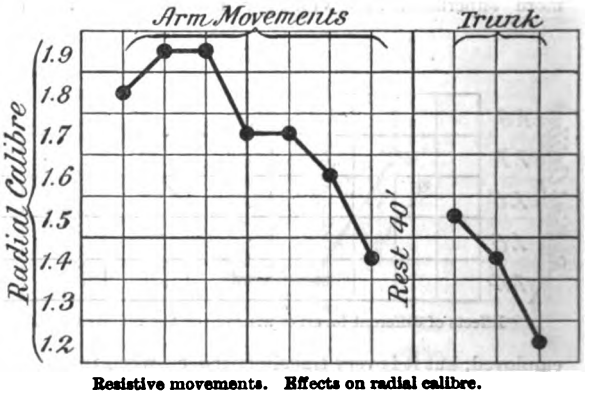
RESISTIVE MOVEMENTS.

It is scarcely necessary to remind you that for many years it has been known that certain exercises in which the operator offers resistance are of special value in the development of the muscles and in the acquirement of muscular tone and vigour. The system of exercises of this character to which I refer is known as the Swedish system. Nearly fifty years ago Saetherberg of Stockholm applied this method to the treatment of heart disease and reported his results some fifteen years later,[19] and following him one or two other observers have shown the value of resistive gymnastics in cardiac disease. But the method has only of late years acquired prominence as a definite therapeutic mode of treating failing compensation of the heart since the brothers August and Theodor Schott modified it in certain respects and applied it under proper restrictions either in conjunction with, or apart from, the baths administered at Bad Nauheim. The few observations to be adduced refer only to the physiology of these exercises, or, rather, as to how the results which are believed by some to be obtained from them are brought about.[20] Two somewhat conflicting theories are entertained. On the one hand, Dr. Theodor Schott ascribes it to reflex stimulation of the cardiac inhibitory nerves, causing the heart to beat more forcibly and more slowly; on the other hand Dr. Bezly Thorne,[21] Sir William Broadbent, and Dr. John Broadbent refer it to dilatation of the arteries supplied to the muscles.[22] I have merely to submit a few observations on several healthy subjects—ranging in age from thirty-two to forty-six years—which may be regarded as having a bearing on one of these views.

In one case, a healthy medical man aged thirty-seven years, the five arm movements were distributed over thirty minutes, the intervals of rest being equal to the duration of the exercises. At the termination of the first exercise the calibre was found to be two points and the pressure ten points higher; but after each of the four subsequent exercises the calibre and the pressure were observed to fall rapidly, and at the close of the observation the former was found to be nearly 1 m.m. and the latter thirty points lower than the initial records. The frequency of the pulse fell from 88 to 82 (sitting).

In another case, a healthy man aged forty-six years subjected for thirty minutes to the arm exercises followed by forty minutes' rest and then succeeded by the three trunk movements, there was also an initial rise of radial calibre and pressure followed by a rapid fall; and after the long interval of rest this reduction was further intensified by the trunk movements (Fig. 10). The pulse-rate fell from 84 to 74 sitting.

FIG. 10.



Resistive movements. Effects on radial calibre.

In a subject aged twenty-six the volume of the arm was measured before and after four arm exercises of two minutes, each interrupted by one minute of rest. The initial volume of 1648 c.c. was increased to 1696 c.c. and the increment was entirely removed by the application of massage for fifteen minutes, and was replaced by the resistive movements for ten minutes (Fig. 11). It has been observed that the increased volume caused by the resistive exercises may persist for several hours.

These observations in healthy subjects have shown that the slow resistive exercises adopted by Dr. Theodor Schott produce the following effects on the limb and on the radial pulse: (1) an increase in the volume of the limb; (2) at first a rise and then a decided fall in radial blood pressure and calibre; and (3) a reduction of the frequency of the pulse.

[17] See a Treatise on Massage, by D. Graham, M.D., New York, 1890.

[18] The diminution is by no means invariable. I have repeatedly measured an increased volume of the arm after vigorous massage for fifteen minutes. Apparently the initial contraction of the peripheral vessels which causes the diminution is soon replaced by dilatation of them when the volume of the limb increases, even though centripetal or amatriptic massage has been thoroughly applied.

[19] Hygeia, 1862, quoted by Dr. Hermann Nebel of Frankfort, THE LANCET, April 11th, 1896.

[20] It is beside my purpose to touch upon the disputed clinical question as to whether either the immediate or the remote effect of the exercises is to actually reduce the dilatation of the cardiac chambers or only to apparently do so. Reference should be made to an instructive contribution by Dr. Leith bearing on this point and on the physiology of the resistive exercises in THE LANCET of March 21st, 1896.

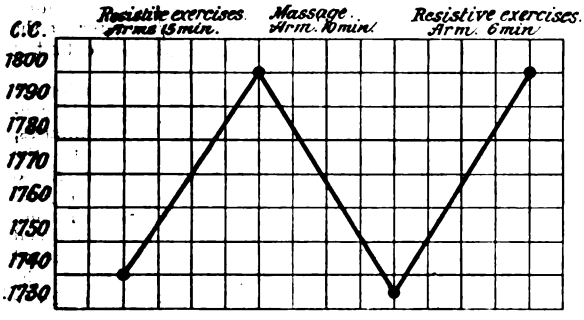
[22] The Practitioner, vol. liv.

Digitized by Google

The reduction of the radial pressure and calibre is no doubt due to the diversion of a large volume of blood to the capacious muscular periphery. The immediate increase of the volume of the limb is direct proof of this fact; but, as in ordinary exercise, the persistence of the enlargement for many hours shows that it is not due entirely to the temporary filling of the vessels within the muscles, but probably arises from an infiltration of fluid derived from the blood into the

FIG. 11.



Resistive movements and massage; contrary effects on arm-volume.

muscular tissue. This position is, moreover, confirmed by the results of an examination of the blood to which reference will be made in the last lecture. It is, therefore, obvious that this system of regulative movements produces all the local physiological effects of exercise; but it prominently differs from ordinary exercise in one respect—namely, in the slowing of the heart's action.

It has been shown that in general exercise the condition of the radial artery does not truly indicate the degree of tension that exists within the central arterial system from the augmented propulsion of blood into it, for the blood pressure at the point of observation is reduced by the dilatation of the branches which at higher points convey the increased flow of blood to the muscles. In the early stage of exercise the radial tension is increased; but this increase is transitory and is replaced by a reduction when the muscles begin to monopolise the blood supply. Exactly the same thing occurs as a result of the resistive exercises. As a matter of fact it is known that in general exercise there is an increase of the mean blood pressure, notwithstanding the enormous diversion of blood to the muscles.[23] But if the resistive movement method is but a form of exercise, why should it slow the heart while exercise accelerates it? It may be presumed that there is in both a rise in the mean blood pressure. According to Marey's law there should be in both a slowing of the heart's action. In exercise it is obvious that the operation of this law is disturbed by other concomitant conditions, which determine an acceleration of the vascular pump, and by the increase of the respiratory movements. Now when the resistive exercises are practised the greatest care is taken not to allow the movements to accelerate the patient's breathing, and he is directed to breathe calmly and regularly, so there is eliminated from this mode of exercise the main, if not the sole, cause of the acceleration of the heart which is invariably present in ordinary exercise, and the slowness of the vascular pump is just as likely, perhaps more likely, to be due to a slight rise in the intra-aortic pressure as to reflex cardiac inhibition (the theory of Dr. Theodor Schott). The former view, which was pointed out by Dr. Saundby,[24] is more in accord with our knowledge of the physiology of exercise than the latter; and, moreover, it affords a reason why the exercises are regarded by Dr. Schott and others as unsuited to cases of myocarditis, of aortic aneurysm, and of advanced arterio-sclerosis. The examination of the radial pulse by means of the finger and of the sphygmograph affords but equivocal evidence bearing on this point, and from what we know of the anatomical relations of the radial artery to the muscles, and of the physiological influence of the circulation through the muscles on the radial tension, it becomes, I think, somewhat doubtful if the radial pulse can afford trustworthy evidence of any alteration in the blood pressure which may be induced in the large arteries by the exercises.

[23] A Text-book of Physiology by Professor M. Foster, F.R.S., p. 350.
[24] Brit. Med. Jour., vol. ii., 1896, p. 1081.

It should be observed that the retardation of the heart's action as well as the copious delivery of blood into the muscular periphery must greatly limit and reduce any rise of arterial blood pressure that may take place. Hence these modulated movements throw less strain on the central arteries than ordinary exercise. The slowing of the heart is, therefore, a favourable sign; for it is an indication that the rise of blood pressure is being reduced by inhibition and that the ventricle is not being subjected to an injurious strain by the exercises, and is duly responding to them in a more complete delivery of the blood. Doubtless the immediate relief to the loaded heart afforded by this therapeutic method should be ascribed to the aspiration of a large volume of blood into the capacious muscular periphery by means of the tonic contraction of all the systemic muscles, so gentle and so maintained as just to fall short of stimulating the respiratory centre.[25] The blood thus determined to the periphery must gradually return to the heart; and if the relief obtained is entirely due to this diversion of the blood it will be of comparatively short duration. But there is some reason to believe that the volume of the blood is reduced during its sojourn through the muscles, and if the fluid withdrawn from the blood lodges for some time in the muscular tissue the intervals of relief should be prolonged.

The total outcome, therefore, of the exercises is a transference of blood from the venous to the arterial side of the circulation and a probable reduction of the volume of the blood. My observations support Dr. John Broadbent when he says: "The slow movements of each limb bringing into action different groups of muscles in turn causes a flow to those muscles. The contraction of the muscles being slow and gentle does not rapidly force out the contained blood or compress the veins, so that by the time each group of muscles has been brought into action the vessels in them are dilated and full of blood. Hence a large amount of blood has been withdrawn into the muscular system; this gives relief to the heart, tending to empty the left ventricle and enable it to contract down more completely on its contents. At the same time the peripheral resistance is lessened by the vascular dilatation, so that the left ventricle is better able to drive the blood through the system. The backward pressure in the left ventricle being diminished the obstruction to the flow of blood through the lungs is lessened and the right ventricle is relieved. Further, the arterioles and capillaries being dilated will receive a larger proportion of blood, which will be transferred from the venous to the arterial side of the circulation. The venous stasis and turgescence which give rise to the hepatic enlargement are thus relieved and the liver diminishes in size."[26]

Since making these observations I have had but few opportunities of testing the application of them to patients. I am indebted to Dr. Kingscote of Salisbury for one such opportunity. In that case—an anæmic woman aged fifty-three—the arm volume was increased, but only to a little over 16 c.c., after the gentle application of the resistive movements to the arms only for twenty minutes (including the intervals of rest). The large area of cardiac dulness, superficial and deep, was undoubtedly lessened. The frequency of the pulse was reduced from 80 to 76 (sitting) and from 72 to 68 (recumbent). The reversed radial calibration (1·3 mm. sitting and 1·6 mm. recumbent) was restored after the movements (1·7 mm. sitting and 1·2 mm. recumbent), so that in this case it may be inferred that there was before the movements an excess of blood on the venous side of the circulation which disappeared after the movements. As a result of the exercises we have, on the one side, reduction of the cardiac dulness, and, on the other, a greater charge of blood in the systemic arteries and an increase of the limb volume.[27] I think it is not improbable that under physiological conditions the ventricular output is not, as a rule, ample enough to maintain the normal volume of blood in the arteries while they are being largely depleted by the increased drain into the muscles in a state of vigorous contraction, whereas when the ventricle is dilated—which involves dilatation of the other chambers of the heart—and can be incited to throw off the augmented load of residual

[25] Dr. Harry Campbell has also pointed out that the total delivery of blood to the right heart is lowered in consequence of the contraction of the muscles compressing the veins (splanchnic and systemic).—Brit. Med. Jour., vol. ii., 1895, p. 1325.
[26] On Treatment of Chronic Heart Disease by the Methods of Dr. Schott of Nauheim, by John F. H. Broadbent, M.D.Oxon.—Practitioner, vol. liv., 1895.

Digitized by Google

blood, the arterial tension may rise in spite of the increased flow into the muscles. That seems to me to be the reading of the facts which I have observed. When compensation is restored by the exercises "there is thus" as Sir William Broadbent says, "a transfer of blood from the venous to the arterial system, which is the exact reverse of the tendency attending most forms of heart disease."[28]

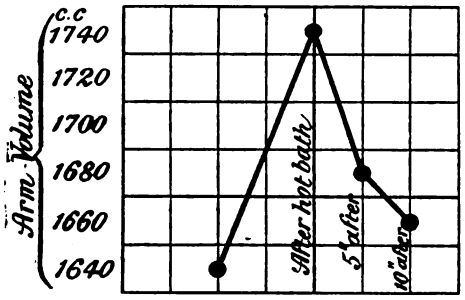
Before leaving this subject I must express my conviction that this strictly physiological mode of developing and invigorating the walls of the heart, when applied with proper care and discrimination, is a therapeutic method of some value, and is a distinct addition to our resources for the treatment of failing compensation of the heart. I have observed several times that it has restored compensation after the complete failure of drugs and that it is in suitable cases a useful auxiliary to other treatment. Like any other remedial method of decided power, it may do harm when inappropriately or improperly applied. In all cases I have found that the greatest caution should be exercised—especially in the early application of the method—to reduce the rate of the exercises to a minimum. There is often a disposition on the part of the operator to quicken the speed; that should always be deprecated unless this acceleration is fully warranted by the improvement attained. There is no reason why the principle which underlies this physiological method of treatment—namely, tonic contraction of successive groups of muscles—should not be attained in other ways and especially by mechanical means. Much may be done by the patient himself without an operator, and it has been found that auto-resistive exercises are useful in maintaining the advantage gained in the first instance by the ordinary application of the method.

BATHS.

The influence of baths on the circulation is too large a subject to be dealt with in the few minutes that can here be devoted to it. I will, therefore, touch quite briefly on only one or two points. Apart from the modifying influence exerted by the constituents of mineral waters, it may be said that the leading effects of baths on the circulation are due to temperature; and as the results of observation with the arteriometer coincide with the generally accepted views on the influence of baths and temperature on the vasomotor system I will merely state the conclusions which they support.

Hot immersion baths (from 100° to 105° F.) quickly reduce the radial calibre and pressure from the rapid dilatation which takes place in the arterioles and the cutaneous periphery. From this cause the volume of a limb taken immediately after the immersion is found to be considerably increased, but the increment rapidly subsides. In one example, the initial volume of 1640 c.c. was raised by the hot bath to 1744 c.c., which fell in five minutes to 1680 c.c. and in ten minutes to 1664 c.c. (Fig. 12). The

FIG. 12.



Hot bath. Transitory effect on arm-volume.

enlargement is obviously due to a temporary tergescence of vessels, and therefore differs from the persistent and larger one caused by exercise.

Warm immersion baths (from 96° to 100° F.) enlarge the radial calibre, though after a certain time the peripheral vessels become relaxed and filled and the radial is consequently reduced.

Turkish baths, like hot immersion baths, quickly congest the cutaneous peripheral vessels and the veins and consequently reduce the arterial pressure. When followed by the cold shower the arterial pressure immediately rises, and the radial calibre consequently increases, but may not quite attain its former size. It will be shown in the fourth lecture that the volume of the blood is frequently much reduced.

Hot foot-bath.—The well-known revulsive action of the hot foot-bath in reducing the arterial fulness in the upper part of the body has been illustrated by the arteriometer, for it has shown that an immersion of twenty minutes may reduce the radial diameter from 2·2 mm. to 1·3 mm. The same fact was demonstrated by Winternitz as the result of the warm sitz-bath, for he found that the plethysmograph indicated a reduction of the size of the arm,[29] and Schüller observed that the vessels of the exposed pia mater of the rabbit were diminished in size in proportion to the extent of the body immersed in warm water.[30]

Cold baths.—It has been observed that immersion in plain water of temperatures below 90° F. produces contraction of the systemic arteries within three minutes, the amount of contraction being proportionate to the reduction of the temperature. For example, a radial calibre of 2·2 mm. in a subject aged twenty-two years was diminished by 80° F. to 2·0 mm; 70° to 1·7 mm.; 60° to 1·5 mm.; 50° to 1·4 mm.; 40° to 1·3 mm. It would seem from the experiments of Schüller that the blood thus averted from the outer vascular area congests the vessels within, for on immersing rabbits into cold baths he observed dilatation of the vessels of the pia mater (exposed by trephining) in proportion to the extent of immersion.[31] This diversion of the blood from the surface is, however, but temporary and is followed by increased fulness of the systemic vessels after the immersion is over, or even while it continues if the subject is very vigorous. The local application of cold water—as in the cold sitz-bath—is also of considerable therapeutic power when the principal aim is to divert an increased quantity of blood to the brain and the cord, as when the vasomotor mechanism is impaired and gravitation determines anæmia of the nerve centres. According to the observations of Winternitz[32] the cold sitz-bath increases the volume of the arm as registered by the plethysmograph, so that it possesses the power of increasing the distribution of blood in the upper parts of the body. We have here a reasonable explanation of the clarifying effect of the cold sitz-bath on the mental haziness and dulness consequent on cerebral anæmia from impaired vasomotor compensation.

Shower, needle, and douche baths.—The influence of temperature *per se* is greatly modified by the mechanical agency of percussion and vibration, so that when the water is divided into innumerable fine jets, which impinge all over the surface of the body with a certain degree of force, or when it is applied in the form of the travelling douche accompanied by a vibratory form of massage, the vasomotor system is much more powerfully affected than by any form of still bathing, even though the water be charged with carbonic acid or saline matter. The therapeutic advantages of this form of bathing are very considerable, for it can be made to furnish all the tonic effects of cold bathing along with an agreeable temperature that may be adapted to individual requirements. A most intelligent appreciation of the curative value of this and of similar forms of tonic bathing now prevails at many health resorts where in times gone by a course of bathing often simply meant soaking in hot water with the consequent impairment of the vasomotor mechanism. The massage-douche and needle-bath is the form of bathing best of all adapted to counteract the enervating effects of city life with all its attendant worries and anxieties; and were it established in our large centres it would, I am persuaded, prove to be a boon to many sufferers from nervous exhaustion and would become even more popular and valuable than the Turkish bath.

Carbonic acid and saline baths also belong to the stimulant form of bathing. Fig. 13 illustrates the effect of a carbonic acid bath produced by Dr. Sandow's tablets on the volume of the arm. The subject was a young man aged twenty-three years. The volume of the limb after the twenty minutes'

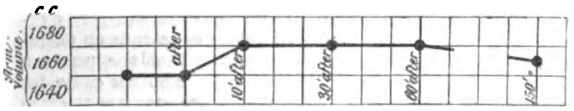
immersion in the bath of 94° F. was found unaltered; but in ten minutes it was observed to have increased 32 c.c. and at the termination of two and a half hours it was still slightly above the initial measure. In this instance the increase of

FIG. 13.



Carbonic acid bath. Persistent increase of arm-volume.

volume followed the immersion and seemed to be due to the reaction set up by the bath; but this reaction is common to all forms of tonic bathing.

The subject of baths will be touched upon in the fourth lecture, when reference will be made to their effects on the blood and on the interchange of fluids.

The Erasmus Wilson Lectures

ON

THE GENERAL PATHOLOGY OF BONE.

Delivered before the Royal College of Surgeons of England on March 16th, 18th, and 20th, 1896,

BY W. G. SPENCER, F.R.C.S. ENG.,

SURGEON TO THE OUT-PATIENTS AND THROAT DEPARTMENT, WESTMINSTER HOSPITAL; LECTURER ON PHYSIOLOGY AT THE WESTMINSTER HOSPITAL MEDICAL SCHOOL, ETC.

LECTURE III.[1]

Delivered on March 20th.

THE NEW FORMATION OF BONE.

Ossification in tendons and ligaments.—A simple type of ossification is met with in the tendons of birds. The tendon cells first multiply, forming rows of cells separated by very regular spaces. Between these cells are deposited small granules of lime salts, which become more and more refracting, hard, and homogeneous until the fibrous tissue of the tendon can no longer be seen. The fibrous tissue none the less remains as the framework of bone and its presence is revealed in the septa whenever they become decalcified. Along with this process of calcification there are seen vessels running parallel to one another in the long axis of the tendon. It is around these vessels that true osseous tissue is formed so that these channels become Haversian canals and the osteoblasts commence at the periphery and work inwards until complete Haversian systems are formed. This ossification in tendon, which is normal in birds, may exceptionally occur in man by extension from the ridges of insertion into the tendons as muscular exostoses, or even into the muscles in myositis ossificans. Ossification may extend from the periosteum into the ligaments about a joint and form the first stage of bony ankylosis.

Ossification in cartilage and in membrane.—No sharp line of distinction can be drawn between periosteal and endochondral ossification. Even in periosteal ossification a matrix surrounds the osteoblasts which stains deeply with logwood. Indeed, in fish ossification in cartilage starts from the perichondrium and spreads inwards. So also in tumours new bone may be formed directly in membrane or cartilage may arise in the tumour even when it grows from the periosteum. This cartilage may continue unaltered or afterwards ossify. Epiphyseal ossification does not essentially differ from that which takes place in fœtal cartilage. The single exostoses of the long bones are said to be due to displacement of bits of epiphyseal cartilage. The cartilage itself not only grows but in addition forms bone and becomes a cap covering the surface of the exostosis. The multiple exostoses are accompanied by diminution in the growth of the long bones. Exostoses may be developed, however, solely from membrane bones, as in the case of the skull-cap and face. Cartilage may never go beyond the stage of becoming calcified, no vascularisation taking place. Such calcification may be considered as a regular senile change more or less well marked in the rib cartilages and in those of the larynx. Likewise calcification may occur in the pure enchondromata without going further.

The grafting of bone.—In a previous lecture the relations between bone and the epidermis have been detailed. Bone, like skin, hair, horns, and teeth, can under certain conditions be transplanted. Bone may be made to form where it otherwise would not by grafting living periosteum and bone. One certain plan of ensuring a formation of bone which will not afterwards undergo absorption is by raising a flap of periosteum with a superficial layer of bone attached by means of a chisel (Schimmelbusch). Such a flap raised from the forehead including the outer table of the skull may be turned down so as to make a satisfactory bridge to the nose, but this may not be the case if only periosteum be turned down. Similar grafts of living bone have been made by taking chips of periosteum and bone from an animal just killed and planting them where a formation of bone is desired. In some cases the actual cells of the transplanted bone do not take part in the new bone formation, but oteoblasts come in from the outside. In such cases the transplanted bone merely acts as a scaffold. A great number of experiments have been made on the skull, but the skull is peculiar in that the pericranium and dura mater take little part in bone formation. Whether a disc removed by a trephine be replaced in the trephine hole intact, or whether it be cut in small pieces, or whether it be kept for some time in an antiseptic solution before being replaced, in any case the fact of replacing will allow of the gap being filled by bone, a process which would otherwise take place but incompletely. But the formation of new bone appears to be brought about wholly by cells which are derived from the bone around. These arise chiefly by active multiplication of cells in the marrow of the diploë and but to a small extent, if at all, in the pericranium and dura mater. The bone corpuscles of the actual graft degenerate, as seen by their losing the property of staining with logwood. The graft to the naked eye certainly becomes vascularised, but on microscopical examination new bone is seen to be laid down upon the old septa part, which act like the calcified trabeculæ in normal ossification and slowly disappear. Whilst both co-exist the new bone layers are distinguished from the old septa by the staining of the cells in the new, whilst in the old septa only blank spaces are left by the early disappearance of the bone corpuscles. It is a kind of metaplasia or substitution for dead bone (Barth). But the graft is of service not only as a scaffold, but also as affording a supply of lime salts. Many pieces of bone have been put into strong antiseptic solutions or into alcohol before being used, and yet have determined the formation of bone when transplanted, likewise dried bone or ivory chips have been employed, and finally plaster-of-Paris has been used as a filling for cavities in the bone (Martin). In all these cases the actual supply of the lime salts appears to be of advantage. But the transplantation of living periosteum and bone, as well as the insertion of dead bone to serve both as a scaffold and a supply of lime salts, are not the only means by which osteogenesis may be excited. A distinction must be drawn between the experiments made upon the skull, in which one has chiefly to depend upon the cells of the diploë, and that of a long bone where the periosteum is the principal factor. A certain amount of irritation, by increasing the vascularity of the periosteum, may ensure the formation of bone. Thus, in a limb after necrosis of the shaft the periosteum became a fibrous band without making any attempt to re-form the shaft. This band was split and plugs of wool soaked in turpentine inserted. By this means the blood supply to the periosteum was so increased that the whole bone was re-formed (Mikulicz). In other cases of delayed union an improvement of the blood-supply to the periosteum has been caused by rubbing or scratching the ends, injecting chloride of zinc, or by inserting pieces of decalcified bone. In some cases suppuration has followed grafting, and the grafts have been discharged, nevertheless the new bone formed. For the new formation of bone, therefore, the normal process of ossification holds good and the presence of (1) actively osteogenetic cells, (2) sufficient lime salts, and (3) a good blood-supply are necessary; but a distinction must be drawn

[1] Lectures I. and II. were published in THE LANCET of May 30th and June 6th, 1896, respectively.

Digitized by Google

between cases in which periosteum still exists and those in which it has been destroyed, or, as in the skull, is naturally inactive. In the former cases where periosteum still exists, as in a long bone after necrosis of a large part of the shaft, any irritation tending to increase the blood-supply will suffice. In the latter case where periosteum has been destroyed—e.g., in the case of an injured nose or for a gap in the skull—living periosteum and bone will be required either by a flap or piecemeal from an animal. There is a danger of re-absorption nevertheless, even after new bone has formed. On two occasions I assisted Mr. Edmund Owen to graft living periosteum and bone direct from a puppy just killed for ununited fracture of the leg belonging to the class of "essential non-union of fracture in children." On both occasions firm union progressed and lasted for about six months, after which bending again took place at the site of the fracture.

ON THE CHANGES PRODUCED IN BONE BY NEW GROWTHS.

The essential feature of a new growth is the continued proliferation of cells. As the tumour grows the cells absorb bone and spontaneous fractures may occur. The disease, as far as the bone is concerned, may be purely local, spreading beyond solely by way of the soft parts without further involving bone. Like new growths of other tissues, that attacking the bone may be regarded as a kind of inflammation; indeed, the new growth frequently begins in a part which has before been the subject of chronic inflammation. But the special features are only seen when one bone is involved widely, or several bones, or, indeed, the whole skeleton by primary or secondary new growths. This is the most complex part of the whole subject dealt with in these lectures, for in order to give an explanation of the changes connected with extensive new growths of bone we must employ one or more among the results drawn from the conclusions already arrived at. In noting some of the chief forms of new growth *seriatim* it must be remembered that these are but types and that all kinds of intermediary stages may be met with.

Periosteal sarcoma.—The most important feature of a periosteal sarcoma is the rapidity with which this form of new growth extends beyond the bone by way of the lymphatics to the lymphatic glands. It is an error to distinguish periosteal sarcomata from the carcinomata by saying that the latter invade the lymphatics and glands more quickly than do the former. In the treatment of periosteal sarcoma it is just as important to remove the lymphatics and glands receiving the drainage from the part involved by the growth as it is in the case of a scirrhus of the breast. By reference to comparative physiology and embryology as well as to pathological conditions I have already shown the close relationship which exists between the cells which form bone and those which give rise to epidermal structures.

Central sarcomas—myeloid sarcomas.—As compared with the periosteal growths myeloid sarcomas tend to remain confined to the bone for a considerable time. The giant cells which are present in the tumours slowly absorb and enlarge the marrow cavity whilst periosteal bone continues to form. Finally, a mere shell of bone encloses the tumour, but until this shell is perforated the disease remains purely local.

Myelomas or lympho-sarcomas.—Myeloma is but rarely met with as a single and local tumour from the marrow. Generally it is multiple, the skeleton is widely involved, and multiple fractures or softening and bending with cystic formation may be seen. But besides this there is always more or less disease of the spleen and lymphatic glands, the latter not being situated specially in the neighbourhood of the bone tumours. In the myeloid tumours we have instances of great absorption only, the cells acting like phagocytes; the myelomas, on the other hand, illustrate in addition the connexion of the marrow with the spleen, lymph glands, and with blood formations, to which reference was made in the first lecture.

Cancerous mollities ossium or osteomalacia.—Malignant tumours which begin in a soft part may secondarily infiltrate bone, whether they be sarcomata or carcinomata. Carcinomas, especially those of the breast, thyroid gland, and prostate, may secondarily attack bone even when the primary growth has been of the atrophic scirrhous type and relatively very small. The bones chiefly attacked are the pelvis, the upper half of the femur and humerus, the skull, vertebræ, and sternum. Softening and bending and multiple spontaneous fractures are among the chief signs. Besides the property the cells of the growth have of absorbing bone we must recognise in some cases a further rapid absorption from an increased arterial blood-supply. Pains in the bones may be acutely felt and after death they are found very vascular and may be cut with a knife. On microscopic examination invasion by the new growth may be seen, although there need be no distinct tumour. The term "cancerous osteomalacia" is often used for such cases, and the so-called osteomalacia of a single bone, the pelvis excepted, will generally prove to be really cancerous on microscopic examination, it being remembered that the presence of a tumour is not necessary (Bramann). Another cause for the wasting of the bones is the cachexia occurring as the case progresses from the impairment of general nutrition checking the normal rate of periosteal formation whilst absorption goes on, producing the so-called "eccentric atrophy." Post mortem such bones will appear anæmic, and filled with a yellow marrow as distinguished from the red colour of the marrow actually infiltrated by cancer. But in other cases of new growth, especially those which progress but slowly, or which having begun as a chronic inflammation gradually become malignant, there may be excessive bone formation. This bone formation may either be an osteo-sclerosis, a formation within the normal limits of an unusual amount of compact bone, or an excessive growth beyond the normal limits, a hypertrophy of bone, either of cancellous or of compact bone. In such cases we shall find signs of venous congestion, and may recognise in it this factor as determining the excessive formation of bone in the case of new growths in addition to the observations already brought forward. For such cases, besides osteitis deformans, other names have been used, such as hyperostosis, osteo-sclerosis, condensing osteitis, cranio-sclerosis, or spongy hypertrophy of bone. It was noted by Sir James Paget that whereas the condition in the bones was for a long time that of chronic inflammation new growths appeared later in a number of cases. It is extremely difficult or impossible to draw the line between the results of chronic inflammation and of the new growth, but we can regard the venous congestion as the immediate cause of the bone production in both cases. The whole bone becomes enormously enlarged, of a uniformly porous texture, the medullary canal obliterated, and an interstitial growth in length may ensue. There is, however, some evidence of absorption, as seen in the bending of the bones, the sinking together of the vertebræ, spontaneous fractures, and, moreover, a diminution in the percentage composition of the mineral salts has been found. Sometimes osteitis deformans seems to take the place of the atrophy which may occur in old age. Thus it was seen in a woman aged eighty-eight years as well as in her daughter aged sixty years, both of whom were suffering from senile dementia (Gilles de la Fourette, Marmesco, and Chaffard). In other conditions the disease is more limited in extent—as leontiasis ossea and multiple exostoses. These hypertrophic forms of new growth occur in the distribution of the fifth nerve. There may possibly be some disturbance of the regulatory action of the nerve akin to that which allows of the new formation of bone in osteo-arthritis and locomotor ataxia. During operations these growths have been found exceedingly vascular and the newly-formed bone may be softer, more porous, than is the bone from which it grows, or, on the other hand, so hard as to approach the texture of ivory (Horsley).

Symmetrical new growths: Osteoporosis in animals.—The term osteoporosis has been used in various ways in human pathology, but since Varnell applied it to a particular disease which he noted in the horse the word has been on the whole confined to this disease in veterinary pathology. The disease is also common in the United States under the name "bighead" and is generally attributed to cold and damp. As a matter of fact, nothing is known as to the cause. I have described a number of cases which occurred in goats and have examined sections of the new growth microscopically. The disease commences bilaterally about the angles of the lower jaw, in the part of the bone to which the masseters are attached. It progresses with exact symmetry, and as the bone enlarges it becomes softer so as to yield to the pressure of the finger and may be easily punctured. As the jaws enlarge into a tumour on either side swallowing becomes more difficult and the goats I saw had to be killed or they would have died from starvation. The upper jaws, the frontal bones, and the ends of the long bones had already begun to suffer. On the examination of a macerated specimen the original bone is seen to have been replaced by very spongy new bone, which is in its turn

Digitized by Google

being gradually re-absorbed until a mere shell in the outer wall of the tumours is left; a microscopic section of the growth does not materially differ from myeloid sarcoma. There is a remarkable symmetry in the disease which is striking.

Symmetrical periosteal new growths.—Another instance of symmetry in new growths is shown by the case of a dog which I have described and in which *all four* limbs were affected in an exactly similar way. The growth proved to be a fibro-sarcoma attended by some new formation of bone. It is not an isolated case, for an identically similar specimen is in the St. Bartholomew's Hospital museum also. And there are other allied specimens in the College museum from animals. This symmetry is a further connexion between new growths and inflammatory forms of disease and is sufficient to show that nerves may have some influence even in the case of new growths.

A summary of the points dealt with in these lectures may be given as follows:—

1. By a consideration of certain pathological conditions in the light thrown upon the development of bone by comparative physiology and embryology a relationship can be found between the bone-forming cells and epidermal structures, and between the bone marrow and lymphadenoid tissue, which explains the sympathy or co-existence of disease.

2. Alterations in the circulation affect bone: (1) a full normal supply favours bone formation of a normal kind; (2) an excessive arterial supply leads to decalcification and absorption; (3) a diminished supply checks the normal rate of bone formation, absorption going on, and "eccentric atrophy" is the result; and (4) an excessive supply of venous blood, venous congestion, causes pathological bone formation. The parts of bone most subject to an excess of the arterial or venous circulation are during earlier years the epiphyseal ends of growing bones and during later life the parts of the bones most subject to pressure and to the pull of the muscles.

3. The nerve influence on bone appears to be regulatory in action; when disturbed the formation of bone may be either in the direction of excess or of defect or of both combined. It transforms bone so as to accommodate structure to altered function.

4. Impairment of the general nutrition decidedly influences bone by diminishing the rate of formation, and its effect will differ according to age and the various incidents accompanying the different stages of life, such as childhood, puberty, pregnancy, old age, &c.

5. For the new formation of bone the normal process of ossification holds good, and the presence of osteogenetic cells, lime salts, and a sufficient blood-supply are necessary. Granted the artificial supply of one, two, or of all three of these factors, when they chance to be deficient, the new formation of bone may be brought about. A distinction must be drawn between bones, such as the skull, where the periosteum is naturally inactive, or where it has been destroyed, and periosteum which can be re-awakened to activity.

6. New growths which widely affect the bones serve as further illustrations of the points before noted; the conditions are not essentially different from those present in other diseases, such as inflammation, only they are more complex.

Conclusion.—It is clearly impossible so sharply to describe any general disease of bone as to separate it from others. When considering any particular case we should strive to group pathological changes under the headings which I have given. I have not fully treated the subject—there are many topics of interest in connexion with fractures and also with the infectious diseases of bone; but these matters are given at length in text-books and in systematic treatises. I have been able in these lectures to call attention to an interesting subject, and others with better opportunities will doubtless be able to extend it and especially to improve our knowledge concerning the causes of these diseases. At any rate, I have attempted to link together by their general features some of the specimens of diseases of the bones to be found in the museum of the Royal College of Surgeons of England.

MUNIFICENT DONATIONS.—The Governors of the Bedford Infirmary have adopted designs for a new county hospital to be built at Bedford at an estimated cost of £26,300. Among the subscribers to the fund, which already amounts to £23,000, are the Duke of Bedford and Mr. Whitbread, who have each given £5000.

A LAST WORD ON CHOLERA.

BY THE LATE SIR GEORGE JOHNSON, M.D., F.R.S.,
PHYSICIAN EXTRAORDINARY TO HER MAJESTY THE QUEEN, AND CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL.[1]

IN the course of an article on Asiatic Cholera in the recently published first volume of Dr. Clifford Allbutt's "System of Medicine" Dr. Kenneth Macleod does me the honour to refer to me in the following sentence (p. 910): "As a matter of fact Sir George Johnson's castor-oil treatment has been extensively tried and found wanting." Now as this statement is contradictory of much that has recently been published, and as this subject is one of primary importance, I ask permission to call upon Dr. Macleod to publish the evidence upon which is based his condemnation of the evacuant treatment of choleraic diarrhœa. His own treatment is simply repressive: "1. *Check the preliminary diarrhœa.* All authorities are agreed as to the advantage of this measure, which promptly cures mild cases and prevents others from becoming dangerous. Combinations of opium with astringents and antispasmodics constitute the favourite formula..... If medicines are still rejected the hypodermic injection of morphia may be resorted to." The author evidently does not see that this treatment of cholera in the human subject is in principle identical with that by which Dr. Koch succeeded in producing fatal cholera in guinea-pigs. After introducing the cholera bacillus into the stomach of the animal he injected into the peritoneum a dose of tincture of opium, his object being to render "it possible for the comma bacillus to remain longer and gain a footing in the intestine." In this manner he produced fatal cholera in thirty out of thirty-five guinea-pigs experimented on. Dr. Macleod's treatment of cholera, therefore, may fairly be designated *Koch's guinea-pig treatment.* If, however, this treatment is as successful as the author declares it to be, let him show by statistics what number of cases of choleraic diarrhœa have been treated by repressive doses of opium, and in what proportion collapse has supervened. Happily, the largest doses of opium given by the mouth may be ejected by vomiting and purging, and so may fail to arrest the elimination of the poison, but morphia given hypodermically is certainly and rapidly absorbed, and is, therefore, a more pernicious practice. If Dr. Macleod will do me the honour to refer to a recently published small book, "History of the Cholera Controversy," he will find that I have given the result of opposite modes of treatment. On the one hand, of some thousands of cases of choleraic diarrhœa treated by evacuants not one passed into collapse; on the other hand, Dr. Briquet and Dr. Mignot[2] treated in the hospital 200 cases of diarrhœa admitted at the very onset of the attack by from fifteen to thirty drops of laudanum, the dose to be repeated in an hour and followed by opiate enemata if necessary. The result was that no fewer than twenty-six passed into collapse. When in the epidemic of 1849 I saw that in case after case the arrest of an apparently mild attack of diarrhœa by opium was directly followed by deadly collapse, I saw clearly enough that the repressive treatment and the theory which suggested it must be wrong, though I was at that time entirely ignorant of the true nature of choleraic collapse.

If prior to my experience of diverse methods of treating cholera I could have known that the essential feature of the collapse stage is a greatly impeded circulation through the lungs, and that the immediate cause of this impediment is contraction of the pulmonary arterioles excited by poisoned blood, I think I should have foreseen that to prevent the escape of the poison by opium would be to increase the risk of that perilous contraction of the pulmonary arterioles which is the essential feature of collapse. At any rate, now that we know how completely the impeded circulation through the lungs, with the resulting scanty supply of oxygen, explains all the most striking phenomena of collapse, and how, in the words of Sir Thomas Watson, "it unlocks like the true key the whole of the pathological

[1] This little paper has a pathetic interest of its own. It is the document upon which Sir George Johnson was engaged on the day that his fatal seizure occurred, and shows him ready to stand up for his views till the end.

[2] Traité Pratique et Analytique du Choléra Morbus, 1850.

Digitized by Google

intricacies of the disease," we can see how entirely consistent is the pathological theory with the results of opposite modes of treatment.

AN EPIDEMIC OF PNEUMONIA OCCURRING AT PESHAWAR.

BY JOHN STEPHENSON, B Sc., M.B. LOND.,
SURGEON-LIEUTENANT, I.M S.

DURING the months of December, 1895, and January and February, 1896, an epidemic of pneumonia occurred amongst the men of the 1st Bengal Infantry stationed at Peshawar. I was attached to the regiment at the time and had opportunities of observing all the cases. The following is a short account of the epidemic, the particulars having been as far as possible thrown into tabular form.

There were 34 cases of acute lobar pneumonia with 19 deaths. These occurred during the two months comprised between the middle of December and the middle of February; the first case was admitted on Dec. 17th and the last on Feb. 9th. The regiment left for Jhansi on Feb. 20th, but the epidemic was over by that time, no cases having been received into hospital for eleven days previously. Taking weekly periods the admissions and deaths may be arranged as follows:—

	Admissions.	Deaths.
From Dec. 15th to Dec. 21st	2	0
,, ,, 22nd ,, ,, 28th	2	0
,, ,, 29th ,, Jan. 4th	4	3
,, Jan. 5th ,, ,, 11th	7	2
,, ,, 12th ,, ,, 18th	10	6
,, ,, 19th ,, ,, 25th	3	3
,, ,, 26th ,, Feb. 1st	3	3
,, Feb. 2nd ,, ,, 8th	2	0
,, ,, 9th ,, ,, 15th	1	2
Total	34	19

Thus the epidemic was at its height in the week Jan. 12th to 18th; of the 10 admissions, 8 came in on the 15th, 16th, and 17th, and 3 of the 6 deaths occurred on the 14th. The earlier part of the epidemic was the most fatal; of the 15 cases that came in up to Jan. 11th 11 died; of the 19 that came in after Jan. 11th 8 died. Taking the average strength of the regiment during this time at Peshawar to be the number of men present on Jan. 17th (about the middle of the epidemic), when there were 573 men in the lines, the proportion affected was 5 9 per cent. Of the 34 cases 19 died, or 56 per cent. With regard to the localisation of the disease, of the 34 cases 2 were left apical, of which 2 died, or 100 per cent.; 17 were left basal, of which 8 died, or 47 per cent.; 10 were right basal, of which 5 died, or 50 per cent.; and 5 were double basal, of which 4 died, or 80 per cent. As to the mode of onset, 6 men came to hospital with the disease already developed. Commonly, however, the men developed physical signs of pneumonia a few days (from one to eight) after being admitted; this was the case in 25 instances. The remaining 3 cases were affected with pneumonia after being in hospital thirty, thirty, and thirty-five days respectively, during which time they were being treated for other diseases—2 for ague and 1 for abrasion and consequent erysipelas Of the 25 who developed pneumonia after being in hospital a few days 3 did so after one day, 3 after two days, 4 after three days, 5 after four days, 3 after five days, 5 after six days, none after seven days, and 2 after eight days. The average time was thus four days. In the cases which recovered, since the temperature as a rule fell by a long lysis, the duration of the disease could not be fixed exactly. The acute symptoms lasted in all cases a week, sometimes ten days, and rarely even a fortnight, before any distinct improvement was manifest. Of the cases that died, 15 out of the 19 died within five days of the onset of pneumonia, and 4 at longer intervals up to fourteen days.

Most of the cases presented a definite and somewhat peculiar type of the disease, different in many respects from that usually seen in England. A sepoy would come to hospital in the morning complaining of slight fever, pain in the chest, and a hard, dry cough; he usually said he felt weak and unfit for duty. On examination nothing abnormal would be found in the chest, and the temperature would range from 99° to 101°F., rarely 102°. Such a case was admitted and a stimulant expectorant mixture given. A large number of such cases recovered in a few days and went back to the lines; others, however, after an interval presented symptoms and signs of pneumonia. In such a case, after remaining in the above condition for four or five days, the cough and pain would become worse and an examination would reveal the ordinary signs of pneumonia. Sometimes, however, either the dulness or the bronchial breathing was not well marked, and the signs were fully developed only on the day following. Sometimes the signs continued indefinite for more than one day. The patient now very rapidly became extremely prostrate; delirium came on, first at night, then both by day and night. Often he would be apathetic, sometimes violent, and sometimes in a state of stupor, passing fæces in the bed. The temperature was as a rule not high—from 100° to 101° or 102°; sometimes irregular, and sometimes with distinct and regular morning remissions. Either death occurred at the end of a few days, usually from two to five, or after a week of this condition the temperature fell by a long lysis, leaving the patient very weak and exhausted. Convalescence was long, cases being kept in hospital as a rule from four to five weeks before being able to travel on sick leave.

The early physical signs noted in chests which subsequently (as a rule a day after) showed typical pneumonia were: (*a*) harsh breathing at the apex of the lung the base of which was afterwards consolidated, (*b*) indistinct bronchial breathing without dulness over the base afterwards affected, and (*c*) distinct bronchial expiration, with fine crepitations and no dulness, over the area which afterwards showed the typical signs. Of the 34 cases 5 showed no mental change, 3 were either apathetic or unconscious only, and the remaining 26 were at some time delirious. Four were violent or very violent, and 5 patients passed fæces in bed. As to the time of onset of the delirium, in 7 cases it appeared before the pneumonia, in 4 cases it appeared with it or the day after, in 9 cases it appeared two days after, and in 6 cases it appeared at a later period. Hence the large majority were cases of early delirium. As to prognosis, of the 26 who were delirious, 13 died and 13 recovered; of the 5 who showed no mental change, 3 died and 2 recovered; and of the 3 who showed apathy or stupor, only 2 died and 1 recovered. Early delirium was not more unfavourable than late. Thus, on the whole, delirium was of no account as a factor in prognosis. As a rule the temperature was not high: it often oscillated for many days on each side of 100°. There were no cases of hyperpyrexia, and the highest reached in any case was 104 2°. In half the cases the highest point reached was between 102° and 103°; in 9 it reached at one time or other a point between 103° and 104°. As to the character of the temperature, all kinds were exhibited. In 2 cases it was absolutely intermittent; several were regularly remittent, the difference between morning and evening temperatures being about 1°, thus showing a chart like that of an ordinary pneumonia in England; others showed larger remissions, as much as 3°, and approached the intermittent type. But in 15 cases there was no type at all, and these must be described as irregular; 4 of them might be called very irregular. In one case the first few days showed the characters of the typhoid fever chart.

With regard to defervescence, there was not one typical crisis, though in 1 case a sort of attempt was made, the temperature falling 2° in twenty-four hours. In 2 cases there was a pseudo-crisis followed by lysis; in 3 cases there was a short lysis taking only two days; but in all the rest the temperature fell very gradually. A distinct connexion can be traced between height of temperature and mortality. All the higher temperatures were fatal; only 1 recovered whose temperature at any time went above 103°. As to the character of temperature the two intermittents died; beyond this no connexion can be made out.

Three of the cases were in hospital when the pneumonia commenced, and had been under treatment thirty, thirty, and thirty-five days respectively. The first of these came in with ague, which began in the usual way; the fever, however, never went away, and after twenty-five days the temperature became higher, pneumonia subsequently developing. The second was also in hospital for ague, he had a relapse after

Digitized by Google

cooking his food when naked on the twenty-fifth day after admission, chest symptoms developed, and pneumonia was found on the thirtieth day. The third was in for a slight abrasion of the foot which prevented him from attending parades; this was followed by erysipelas and then by abscess formation; he began to go downhill rapidly, discharges came from his eyes and ears, and a few days before his death pneumonia was found on examination of the chest. In these cases, however, the pneumonia was a complication of a pre-existing disease. The only conditions which complicated a primary pneumonia were pleurisy (distinct physical signs on one occasion only) and diarrhœa (in one patient who died).

The epidemic lasted for two months in the coldest part of the year. It was most intense at the middle of this period, while the earlier part of the epidemic was the more fatal. The general mortality was 56 per cent.; about 6 per cent. of the regiment had the disease. The commonest form was left basal; the mortality of this form was the least. The majority of cases developed pneumonia after being in hospital a few days, during which time they had slight fever unaccompanied by urgent symptoms. In cases that recovered acute symptoms lasted a week or ten days; in the fatal cases death occurred as a rule within five days of the onset of acute symptoms. The epidemic was characterised by the extreme prostration of the cases, the very common occurrence of delirium, which usually came on early, the general lowness of the temperature, the variations in type of temperature met with, the large number of cases in which it was quite irregular, following no type at all, the general defervescence by a long lysis, the long convalescence, and the rarity of complications.

With regard to the etiology of the disease there were appearances at one time of its spread by contagion. Thus the suddenness and severity of the epidemic, and especially the so frequent development of the disease a few days after admission, led us to consider whether infection might not be a factor of the etiology. It appeared almost as if the hospital wards themselves might be harbouring and diffusing the causal micro-organism. Many men were taken from the lines to act as sick attendants, and several of these men were taken into hospital suffering in the same way. Thus a Christian bandsman was being nursed by another Christian, who contracted pneumonia and was also given a Christian attendant; the latter also became ill with pneumonia. This appeared to be a passing on of the infection from the first to the second, and from the second to the third. However, on examining the statistics it was found that in reality the sick attendants were no more frequently affected than the regiment generally. Ninety-five men acted as sick attendants at various times. Of these 11 were admitted into hospital; 5 had pneumonia, the other 6 had not, but suffered from the same kind of short febrile attacks which affected so many of the regiment, and on which, in the majority of cases, the pneumonia appeared to supervene. Thus 5·26 per cent. of the sick attendants contracted pneumonia, the ratio for the whole regiment, as was mentioned, being 5·9 per cent. Had there been any element of infection it is only reasonable to suppose that the men who were exposed to it most constantly and in a more concentrated form should have been attacked more frequently, instead of less frequently, than the regiment generally. It was thought that the men might be going through an epidemic of influenza and that the occurrence of pneumonia might be a complication of this primary disease. Several points are in favour of this view: first, the usual presence of preliminary symptoms—slight fever and cough; secondly, the extreme prostration which accompanied the disease; thirdly, the fact that a number of cases which presented the preliminary symptoms were admitted into hospital and recovered, as a rule, within a week, never developing pneumonia at all; and, fourthly, there was said to be just before the outbreak of this epidemic an epidemic of influenza at Rawal Pindi, eighty miles away, and in Peshawar itself a number of the English population had also suffered from "influenza."

With regard to the first point, it is difficult of explanation if we reject the influenza hypothesis. We might suppose that the pneumonia was central, beginning within the lung substance near the root and slowly extending to the periphery; but it is unlikely that so large a number of cases would present this particular and rare form of the disease. Moreover, the rusty sputa, shallow, quick breathing, and rapid and feeble pulse came on only with the development of the physical signs, and therefore it appears improbable that pneumonia could be existing, even centrally, in the stage of the "preliminary symptoms." It must be conceded that influenza is the most probable explanation of this peculiarity of the cases. Nervous and muscular prostration are well-recognised features of influenza, and in this epidemic were also constant accompaniments of the pneumonia. If, however, we look for confirmation in the direction of the other symptoms of influenza we find very little help. The temperature in the majority of cases was very little raised, even at the first onset; there was never noticed any catarrh of the upper air passages, no running from the nose and no watering of the eyes; the general pains about the body, in the limbs, joints, pelvis, back, behind the eyes or in the head were seldom mentioned and never urgent. Pain in the chest was, however, a frequent complaint, nearly always made on first coming to hospital, before the development of the pneumonia. Except anorexia in a few cases, and one case of diarrhœa, there were no gastro-intestinal symptoms. There was never noticed any subsequent paralysis.

It must be mentioned that the cases of an apparently similar nature taken into hospital during the same period, which developed no pneumonia, did not invariably recover. One or two died with alarming suddenness the day after admission, apparently from sudden cardiac failure. Several lay in hospital for a long time in a state of extreme prostration, requiring one or two sick attendants; one who, like some of the pneumonia cases, was violently delirious required four. Something must, however, be said against the hypothesis of influenza. Whilst there were three other native regiments in Peshawar at the time, this was the only one that suffered in such a degree. About the time of the beginning of the epidemic there were several deaths from pneumonia in another regiment; but this did not last long, and later the same regiment had only 5 cases in hospital from all causes. Another had an average of about 12 sick, while in the 1st the daily number of sick during this time was 40, 50, 60, and 70. Thus the sickness among native troops was largely confined to the 1st Bengal Infantry. The detachment at Fort Jumrood sent back several cases to hospital; the cavalry detachment there remained healthy. Influenza has been styled "pandemic": it affects all classes over a large area of country and does not, as the present epidemic did, pick out one set of men only. Again, the regiment suffered a similar epidemic of pneumonia when they were in Peshawar last, about sixteen years ago. I have no records of this, but the accounts seem to show that it was at least of equal, if not greater, severity. At that time I suppose there was no question of influenza.

The foregoing remarks lead to a consideration of the third hypothesis as to causation. The regiment is one of the few composed practically entirely of Brahmins, and the men are more particular than even the generality of sepoys in their customs and observances. They are required to cook and eat their food when naked, and each man cooks his own; it was with difficulty that they could be got to disregard these customs even when seriously ill in hospital. They wash their hands and legs after going to the latrine; I have seen them doing this almost naked, with only a short shirt on. Their daily bath is taken outside even on cold, raw, and wet mornings. Moreover, they are down-country men, and the winter climate of Peshawar is much more severe than the winters they are accustomed to. The carrying out of the customs mentioned would therefore be more dangerous here than in their own part of the country. In one case at least the influence of exposure could be traced; the patient was admitted for ague on Dec. 11th; when convalescent he one day cooked his food when naked. This was on Jan. 5th; pneumonia supervened on Jan. 10th and he died on Jan. 14th. Here, too, the usual period of five days before pneumonic signs appear is seen. Whether, however, the epidemic as a whole is to be attributed to influenza, or to cold and exposure, or to both causes, can perhaps not be definitely decided. I have to thank Surgeon-Major Cretin, I M.S., in medical charge of the regiment, for his kind permission to use the cases on which this paper is founded.

HOME FOR GENTLEWOMEN, WOODHALL SPA.—At Woodhall Spa there was established last year a home for gentlewomen of limited means needing the special treatment at Woodhall who otherwise would not be able to avail themselves of the valuable properties of that water. The terms are put at the lowest figure possible—viz., 12*s.* 6*d.* per week for board and lodging, including medical supervision, which is given gratuitously.

HEART DISEASE IN CHILDREN.[1]

BY CHARLES W. CHAPMAN, M.D. DURH., M.R.C.P.LOND.,
PHYSICIAN TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART, SOHO-SQUARE, W.

HEART diseases in children did not always claim the amount of attention which they do at the present time. Dr. Henoch, in the opening chapter on Diseases of the Circulatory Organs,[2] says: "Pathological changes in the heart are much rarer in children than in adults. The age causes neither anatomical nor clinical differences of any essential importance." On the other hand, in Dr. T. H. Tanner's work,[3] the author remarks: "It may further be stated that, admitting the comparative rarity of heart disease in childhood, we must, nevertheless, allow that it is far more common than was formerly supposed, and may, perhaps, be still more so if carefully sought for." To the late Dr. Sturges we owe much of our knowledge of the special characteristics of cardiac diseases in children, the Lumleian Lectures of 1894 being among the most valuable contributions on the subject. A little thought will show that heart disease must necessarily in some respects affect children differently to adults, and further consideration will point out where the variation exists. In childhood and youth we have growth and great activity of the organs of nutrition, in later life degenerative changes have to be considered; again, in the former questions of education and games are pressing, while in the latter domestic and business responsibilities are elements in the case that must have their due weight in prognosis and treatment. Dr. Sturges, in the lectures already referred to, shows that the incidence of rheumatism varies even in childhood at different periods. He gives an analysis of 100 cases where post-mortem examinations had been made, the proportion of rheumatic and non-rheumatic being[4]:—

Rheumatic (boys, 22; girls, 32)	54	100
Non-rheumatic (boys, 22; girls, 24)	46	

Ages of the rheumatic:—

Between two and four years	2	54
Between four and six years	4	
At six years old	6	
Between six and twelve years	42	

In children arthritic symptoms do not so generally occur concurrently with the cardiac. In a first attack of rheumatic fever there may be no morbid cardiac sounds until late in the illness or, indeed, until after apparent recovery. Case 1 illustrates that a patient with a mild attack of nodular rheumatism may after an interval show signs of grave cardiac lesion.

Causes of heart disease in children.—These are congenital, or rheumatism, chorea, nephritis (generally from scarlet fever), and dilatation from mural degeneration or weakening during acute fevers. Congenital disease is recognised by the existence of cyanosis of a greater or less extent dating from birth, clubbing of the distal phalanges of the fingers and toes. The exact condition of the heart underlying these symptoms cannot with any certainty be made out; a more or less extensive communication between the auricles or ventricles, narrowing or atresia of the orifice of the pulmonary artery, and transposition of the large vessels are among the causes of congenital heart disease. Although, generally speaking, there is no difficulty in recognising a case of congenital heart disease, it may happen that the symptoms attributable directly to heart disease are so slight and unobtrusive that treatment is applied to the relief of complications without reference to the primary disease.

Four years ago a girl aged ten years came under my care at the Farringdon General Dispensary for a cough which had hitherto resisted treatment. The mother had been told that her child had chronic bronchitis and that the dyspnœa and cough were caused by it. Examination of the lungs gave the signs of chronic catarrh; to the left of the sternum, however, at the second and third spaces an exceedingly loud booming bruit, systolic in time, was heard, its source being evidently a stenosed pulmonary artery. Treatment was chiefly directed towards the avoidance of undue strain on the circulation, and as a consequence the pulmonary symptoms cleared up and the cough abated. There was very little cyanosis in this case.

On looking over the notes of 122 cases of heart disease in children under 15 years of age there were—with a clear history of rheumatism, 91; with a history of scarlet fever only, 4; and 27 with no rheumatic or scarlet fever. Included in the last group are cases of anæmia and some of renal disease. It is highly probable that some of them had had scarlet fever which had not been noticed; others, again, may have had chorea. There are also cases where the only symptoms in a rheumatic attack were slight fever and a little joint pain, the whole illness attracting little or no attention and the cardiac inflammation may have been actually progressing after the apparently insignificant symptoms had passed away. A child under these circumstances will very likely return to active life earlier than he should and the heart mischief be undiscovered until the advent of symptoms cause medical advice to be sought. The following case is an example of grave cardiac disease dating from an apparently trivial illness.

CASE 1.—A boy aged five years came under my care in May, 1895. Two months previously he had a feverish attack with nodules on his arms and legs, but no joint inflammation. The medical man who saw him diagnosed the case as rheumatic and kept the patient in bed for three weeks. On examination the heart was found to be considerably enlarged, the apex being in the fifth space in the nipple line. The heart's action was visible over an abnormally large space. a systolic bruit was heard at the apex and round to the left scapular angle, and the second aortic sound was prolonged and roughened—signs indicating mitral regurgitation and probable aortic incompetency.

Chorea is another well-recognised cause of valvular disease sometimes transient, at other times permanent. The following case shows how heart disease from this cause may be overlooked until symptoms pointing to its existence appear many years afterwards.

CASE 2.—A man aged twenty-eight years was admitted into the National Hospital for Diseases of the Heart for dyspnœa, palpitation, and pain below the ensiform cartilage. He was in his usual health until fourteen months ago, when on attempting to rise in the morning he found he had paralysis of the right side and loss of speech: he recovered from the latter in three weeks and from the hemiplegia in three months. The history was briefly as follows. He had chorea twenty years ago and right hemiplegia with aphasia fourteen months ago, hæmoptysis eight months ago and œdema of the legs five weeks ago. He had always worked hard and for the last four or five years had drunk heavily. On examination the lungs were found to be healthy, the heart was considerably dilated and the impulse heaving; the apex beat was diffused and most marked in the fifth space, three-quarters of an inch to the left of the nipple line; there was a coarse systolic thrill at the apex, a pre-systolic and a systolic mitral bruit at the apex, and a reduplicated second sound over the cardiac area, especially over the pulmonary valves. At times three or even four feeble beats succeeded the systolic mitral bruit owing to imperfect contractions. This patient was quite unaware of his having anything wrong with him until an embolus was washed off his mitral valve and caused hemiplegia: thenceforward signs of heart failure grew apace. The valve lesion thus had its origin in chorea twenty years previously and caused no interference with the man's capacity for hard work until dilatation supervened. It is probable that had the patient lived a steady life he would still be ignorant of his having any heart affection.

Since writing the above the man has died. The results of the necropsy were as follows:—The heart was almost circular in shape, all the cavities were enlarged, the apex was formed equally by both right and left ventricles, and its weight was seventeen and a half ounces; the aortic valve was incompetent, the segments were thickened, rigid, and calcified; the aorta and right coronary artery were somewhat atheromatous; the mitral valve was thickened, with a button-hole slit three-quarters of an inch in length just admitting the little finger; the left auricle was large with markings on the inner surface; and the tricuspid orifice was five inches in circumference. The right lung had a recent infarct two inches in diameter, its base was compressed, and there was

Digitized by Google

much fluid in the pleural cavity; the left lung was œdematous. The liver was enlarged. The kidneys were fairly normal. These notes were taken by Dr. F. S. Wood, the house physician.

Scarlet fever is a cause of special interest since rheumatic fever sometimes follows it; the former is, however, solely responsible for some cases of heart disease. Scarlatinal nephritis and nephritis associated with diphtheria may during their course have pericarditis or endocarditis or acute dilatation may supervene.

CASE 3.—A child aged two years and ten months came under my care on Sept. 14th, 1895, complaining of general ill-health and of a hard swelling at the angle of the jaw on the left side. There was a history of failing health for some weeks, but no definite account of any acute illness. Careful investigation elicited the fact that many cases of scarlet fever had been removed from the immediate neighbourhood of the child's home. Beyond some enlargement of the tonsils the throat was normal; there was a high temperature, abundance of albumin in the urine, besides a large number of hyaline and blood-casts, also adenitis at the left side of the neck. The urine speedily became dark from presence of much blood. Examination of the chest showed considerable increase of præcordial dulness, especially to the left; a systolic murmur was heard all over the front of the left chest below the third rib and in the axilla, a mid-diastolic bruit at the apex, and accentuation of the second aortic sound. As the child got better the mid-diastolic bruit was not audible, but the systolic at the mitral remained. The rapid increase in the præcordial dulness and its subsequent recession were remarkable, and after making allowances for fallacies inseparable from percussion in these cases there must have been considerable dilatation of the heart.[1]

Rheumatic inflammation of the heart in children generally affects both surfaces of the pericardium and the endocardium. In the former there may be permanent adhesion of its two layers, in the latter valvular trouble. Adherent pericardium is often difficult to diagnose. When, however, the parietal layer is itself adherent to the chest wall the latter will be drawn in with the systole and come forward with diastole. Adhesions not involving the chest wall are those generally found and as there are no reliable physical signs indicating this condition its existence is generally a matter of inference. A history of well-authenticated attacks of pericarditis, the existence of an extensive area of cardiac pulsation, and, moreover, the absence of grave valvular lesion—such are the data for a presumption that there is adherent pericardium. The pathological importance of the condition under discussion consists in the fatty degeneration of the myocardium with which it is found post mortem to be associated. In endocardial inflammation and its effects are included the great majority of cases of heart disease that come before us, the valves, papillary muscles, and chordæ tendineæ being all liable to be affected. Valve lesions, whether they are obstructive or incompetent, require hypertrophy of the muscular chambers behind them. When this is sufficient to enable the heart, handicapped as it is, to do its duty, compensation is said to be complete. A person so circumstanced may remain unaware of his having any heart disease until a medical examination in connexion with a life insurance proposal or his candidature for Government service discovers it. Quite recently I was consulted by an applicant for a Post Office appointment who had been "refused for heart disease"; he had had no symptoms, neither was he aware of having had any illness that might cause his heart to be affected. He was an exceptionally well-grown man. On examination a well-marked systolic murmur was heard over the cardiac area, it being loudest at the apex and conveyed to the left scapular angle.

In organic disease of the heart treatment in a great measure has one of two objects—the prevention of disproportion between the myocardium and the work required of it, and, when the want of balance exists, the endeavour as far as may be to restore it. That much can be done by judicious management to meet both these indications there can be no doubt. Besides a compensation or hypertrophy, an opposite condition—a shrinking of the heart—may occur when the quantity of blood to be sent on is diminished. In an interesting paper on Consequences of Narrowing of the Mitral Valve when Occurring in Childhood, Dr. Wilks in THE LANCET of Jan. 2nd, 1886, calls attention to the existence of a contracted mitral in a large number of cases examined post mortem where there was a corresponding narrowing of the tricuspid; and, on the other hand, of the rarity of tricuspid narrowing following upon mitral contraction, and writes: "Dr. B. Fenwick brought before the Pathological Society a large number of cases of stenosis of the tricuspid valve, and in nearly all of them the mitral was similarly contracted. The fact is one of great interest as showing the relation between the orifices of the two sides of the heart, for even if a rheumatic endocarditis had been the starting-point for the change, I cannot but think the size given to the softened and contracting valve was fixed by, and was a measure of, the amount of blood passing through it. The explanation appears easy, since in most cases of stenosis of the mitral the blood is thrown back on the lungs and right side of the heart, so that the latter becomes large and the orifices retain their natural size; whereas in primary obstruction of the tricuspid which allows only a small quantity of blood to pass into the right ventricle and lungs, a diminished supply is sent to the left heart, and in this way its cavities with its orifices would become reduced in size." We are all familiar with the wasted condition of patients with advanced aortic regurgitation owing to the reduced amount of blood sent to the systemic circulation. When a man finds that his income is steadily diminishing and that increased efforts fail to bring it back to the original standard he will best save himself from ruin by reducing his establishment; this is just what nature does.

Diagnosis.—With regard to the special points to be observed in examining children with a view to diagnosis, in acute cases the onset of cardiac symptoms is announced by the intensity of the vital signs. The face has an expression of great distress and anxiety, the breathing is hurried and oppressed, the child is very restless, and inspection of the chest and physical examination afford confirmatory evidence. The pulse may be soft and of low tension and the thermometer may give no certain indications of the gravity of a case. The thermometer in children is no guide as to the character or severity of an illness. I have frequently seen it go up to 104° F. or even higher, simply from the presence of undigested food in the intestine, on the removal of which by a purge the temperature has gone down to normal. The diaphragm is fixed and the breathing thoracic, and a pericardial friction sound may generally be found, even though there is already some effusion, whilst an enlarged area of cardiac dulness will indicate, in a first attack, an increased amount of fluid. In endocarditis a murmur is not always present, and this is to be borne in mind in diagnosis and prognosis.

Prognosis.—Difficult as it most generally is to forecast the issue of a case of heart disease, the anxious parent expects to be told when and how far the child may recover and, if recovery is impossible, the probable duration of life. It behoves us, therefore, to answer these questions as far as possible. A diagnosis having been made of the physical condition of the heart, what are the data on which to form our prognosis? 1. If the cardiac disease was caused by a single attack of rheumatic fever, how long is it since the attack and what has the health been in the interval? 2. If there have been two or more rheumatic attacks, at what intervals have they occurred? 3. The family history. 4. What is the condition of the patient as regards general nutrition? 5. Is there good compensation, or commencing or even advanced failure? 7. If there is heart failure, is it recent or only a stage further on the downward course? The condition of the heart, lungs, liver, and kidneys will help materially in answering this question. 8. Œdema of the ankles.

Accuracy of diagnosis should always be aimed at, and in many cases repeated examinations are required to attain this object. If a long time—say, five or more years—has elapsed since the heart affection began we are able to judge how far the heart and circulation have accommodated themselves to the altered condition and from the way the heart has borne the strain to form some idea how it will bear it in the future. Frequent recurrence of rheumatism at short intervals is always a bad sign. The extent of dilatation will be an index of the healthiness or otherwise of the myocardium and the muscular power by the regularity and strength of the heart's action, and its efficiency as a pump may be gauged by the condition of the pulse and other signs. Aortic stenosis of

[1] I examined the child on Feb. 6th, five weeks after his discharge from the hospital, when the apex was found to be well inside the nipple line and the bruit very faint. The child was the picture of health.

Digitized by Google

moderate extent is the least serious condition; the amount of hypertrophy of the left ventricle will be a guide to its extent. Aortic regurgitation may be so far compensated for as to render its existence but little bar to the enjoyment of life, although patients so affected cannot expect length of days. Anything which provokes dilatation brings the case a stage nearer the fatal issue, besides which fatal failure of the heart may occur any time.

CASE 4.—A youth aged twenty years had rheumatic fever when eight years of age which resulted in aortic incompetency. His parents were in good circumstances, so the boy had every possible care. At seventeen years he began drinking to excess with general loose living, which had continued up to my seeing him last autumn for subacute rheumatism. So well had compensation been obtained and kept up that, in spite of his reckless living for three years, the heart was well up to its work. Stenosis or incompetency of the mitral valve when unquestionably organic demands a guarded prognosis. The amount of difficulty these affections cause to the general circulation is shown more by the state of the pulmonary second sound than by the loudness of the mitral bruit.

As a rule patients with mitral disease are more or less permanent heart cripples. The possibility of the mitral incompetency being dependent upon a remedial dilatation of the heart must be borne in mind. The following case illustrates this.

CASE 6.—A boy aged fifteen years came under my care fourteen years ago. He had been for a long time in a delicate state of health and was then suffering from dyspnœa, palpitation, and anæmia; his impaired health dated from a severe attack of measles. The only morbid sound in the chest was a well-marked bellows murmur loudest at the apex and carried to the left axilla. Sir W. Jenner subsequently saw the patient with me and agreed as to the serious nature of the case. After a few months' rest and treatment the lad went to live with a relative in Paris and I lost sight of him for three years. On his return I found the heart sounds quite normal and no traces whatever of any disease. We had been mistaken in our gloomy forebodings. It is surprising sometimes to witness how even desperate cases improve under judicious treatment. In children we do not meet with atheroma; neither are their minds harassed with domestic responsibilities or business worries. I would therefore urge that, even in cases where the prognosis cannot be other than bad, the possibility of at least a rally should always be borne in mind.

Management and treatment.—A few words may be said with reference to congenital cases and permanent heart cripples generally, whose life, if treatment fails to cure, must be more or less that of an invalid. Most of us who have gone through a long illness can call to mind the useful knowledge we acquired during convalescence, and I would urge most strongly that not only should general education be gone on with as far as possible but also some special subject congenial to the child's taste should be introduced, such as natural history, chemistry, or botany, as a resource in the weary hours to come. It must be remembered that some of the most beautiful writings and musical compositions have been produced by those whose short lives were burdened by incurable and possibly painful disease.

Hygienic management.—Every effort should be made to prevent a recurrence of rheumatism; woollen but light clothing should be worn and early hours insisted upon. If it be possible to choose a locality for residence, one with gravelly soil, not over-encumbered with trees and at a fair elevation should be selected. Valleys should be avoided, not only because the air may be damp, stagnant, or draughty, but the compulsory ascent of a hill at the beginning of a walk is often unadvisable.

Diet.—This should be light and easy of digestion, consisting largely of nitrogenous food so as to avoid flatulence, which by pressing up the diaphragm would seriously embarrass an enfeebled heart; excess of sugar has also to be guarded against for the same reason. Under ordinary circumstances indigestion from an error in diet is easily remedied, but when the circulation is impeded from cardiac disease the gastric mucous membrane shares in the general congestion; consequently its functions are easily disturbed. Moreover, gastric irritation acts reflexly on the heart, causing irregularity of its action. In children especially in the treatment of cardiac disease attention has frequently to be directed from the heart to the relief of morbid conditions in distant organs, thereby favourably modifying the primary disease.

Exercise.—Swimming can rarely be indulged in; it is probable that many fatal cases of so-called cramp are really syncope from heart failure. Cricket and football are games generally outside the capacity of a cardiac patient. Cycling on the level may be allowed in selected cases; the difficulty is for the delicate boy to find a suitable companion who would moderate his pace to that which will not cause distress.

The school question is always a pressing one. I have already dwelt upon the importance of interfering as little as possible with the patient's education. A day school within easy reach of the child's home or a boarding school similarly situated should be selected, the one essential being constant parental supervision. I would advocate the medical examination of all children prior to sending them to boarding schools. Every now and then disastrous results follow the neglect of this precaution. Quite recently I was asked to see a girl aged sixteen years who had just returned from a school in Paris, where she had been only five weeks. She had severe valvular disease (probably congenital) and during the journey to France had caught cold. On her arrival in Paris she took to her bedroom, where she remained until she was fit to undertake the journey home. No medical man would after an examination have sanctioned her leaving home to reside so far away.

In *cardiac therapeutics* we are in most cases able to prescribe our remedies with a fair assurance of obtaining definite results. The pharmacology of drugs acting on the heart muscle and those which modify blood pressure has been so ably worked out that a rule of thumb manner of using them is inexcusable. Digitalis is a medicine of the greatest possible value, but misapplied or unnecessarily persevered in it is powerful for mischief. It is at times advisable to suspend the use of this drug for a while or to modify its action by combining it with other remedies; strophanthus, convallaria, and cactus are all useful in appropriate cases. None of the foregoing drugs should be gone on with for an unlimited period, the heart should be carefully examined at intervals and note taken of the effects of treatment; this is forcibly true with children. About a year ago I prescribed strychnine for a patient to be taken for two weeks. Several weeks, however, elapsed before I saw the patient again, and then I was told that the heart was much better, but my advice was required with reference to muscular twitching and cramps which had recently appeared. I need hardly say the patient was suffering from the toxic effects of the drug. Briefly, then, what class of cases benefit most from the exhibition of digitalis? In aortic stenosis only when there is dilatation of the left ventricle, and then it should be given with iron or strychnine; in aortic regurgitation when the mitral valve is incompetent. The best results in the latter cases are obtained sometimes by a free exhibition of the drug, but the effects upon the heart must be carefully watched and absolute rest in bed enjoined during the time. In mitral stenosis it has not been so useful in my hands as strophanthus. In mitral regurgitation the beneficial effects of digitalis are most conspicuously manifested. Digitalis, in common with other remedies acting directly upon the heart, is not to be prescribed simply because a bruit has been discovered. Mercury is a most useful drug and may be classed as a cardiac tonic; the plan of giving calomel in fractional and oft-repeated doses has in some cases proved specially beneficial. Strophanthus, convallaria, and cactus are each useful in selected cases. Iron, in whichever form appears to be the most suitable, is of the greatest use, but it may be pointed out that pallor alone is not necessarily an indication for its use. Arsenic is a most useful cardiac tonic. I have not found the Schott treatment of benefit in children; the difficulty is to keep their movements within bounds.

Weymouth-street, W.

VITALITY.

organs of the nervous system. Whether we study the peripheral arrangements by which impressions are received from without, or the central organs to which these impressions are conducted, or the intervening fibres which carry the impulses from and towards centre and periphery, we find at varying intervals and of various sizes particles of living matter. In the most important part of the central nervous system of man the action of this living matter is intimately related to all mental operations. Consciousness, thought, will, and intellectual effort seem to be in fact vital manifestations which, regarded from the side of knowledge and experience, are inconceivable in the absence of vitality.

As regards the relation of vital endowments to the material particles, the changes in the position of which with respect to one another are continually occurring, it is probable that the material phenomena as far as they are at present discernible are in their essential nature of the same order as the vital movements of the structureless living matter of an amœba, of a colourless blood corpuscle, of a mucus or pus corpuscle and other kinds of living matter, and these vital movements are in their nature essentially different from every other kind of movement yet discovered.

Whether we trace the development of this most important and elaborate of all the textures of living beings in very simple organisms, or study the changes as they occur in man himself, we cannot but admire the remarkable arrangements by which the most distant organs and parts of the body are brought into intimate relation with the various receiving, originating, and regulating centres.

Not only does the arrangement as well as the development of the finer ramifications of nerves in peripheral and central organs afford evidence of the operation of the formative power of living matter, but the gradual formation and disposition of the most delicate nerve fibres and their special arrangement in different species have been shown to be due to the changes in particles of living matter which in young growing organisms are in great number and are always in structural connexion with the fibres. In the absence of such living particles the integrity of the nerve fibres would not be preserved, nor could their proper function be discharged. From the very first indications of its existence there is evidence, in various parts of the nervous system of the higher animals and man, of temporary arrangements which suffice for the comparatively simple nervous system required at an early period of life. These are gradually replaced by more complex and more lasting structures, some of which there is good reason to think undergo little further change through life.

The central and peripheral parts of every nervous system are in structural continuity from the first, but in the early period of development actual fibres cannot be discerned, though the course of the nerve currents can be followed by indications of more or less interrupted lines of granules made more distinct if the tissue is subjected to the action of very weak acetic acid for a long period of time. The anatomical elements of nerve centres and special nerve organs are for the most part so arranged as to occupy as little space as possible, while in their peripheral distribution nerve networks are usually spread out over an extensive area. But in some situations are developed nerve organs of highly elaborate structure for the performance of special acts. It is through the agency of these that the external world is discovered and made evident to individual consciousness. The substance mainly concerned in this operation is the living matter, which throughout nature is devoid of structure, exhibits spontaneous movement, and consists of comparatively few elements.

Nerve organs, in construction, composition, formation, and mode of action, differ entirely from any known apparatus by which corresponding physical and chemical changes may be effected.

The nature-constructed apparatus and the hand-made apparatus are formed upon different principles, are composed of very different materials, and act in a totally different manner. Indeed, all natural structures and organs being produced by living matter absolutely differ from any things made by us in structure, mode of action, and in the kind as well in the excessively small amount of substances they appropriate and consume in proportion to the amount of work they perform In fact, all natural structures approach if they do not actually reach perfection, and it need scarcely be said not one natural structure or organ has been made in pieces which were afterwards put together, nor is there one that may not be self-repaired to some extent. The material used for action and repair is selected by the living matter of the several tissues and organs from a solution common to all, and appropriated, applied to construction or to take the place of matter changed and converted into waste material during action. All natural tissues and organs are, as we say, evolved in the course of changes in colourless, structureless matter, consisting largely of water, by vital agencies, the exact nature of which we as yet know very little, and to investigate which we have not yet discovered the means.

We are assured that all natural processes are governed according to natural laws, but the terms of the laws have not been determined, and the phrase is repeated again and again without any definite meaning being assigned to it. If this view of natural law be accepted we must surely admit that the so-called "natural law" which governs the non-living part of the universe belongs to a category in which the "natural law" which governs vital phenomena cannot be included. There seems everywhere in the living world evidence of the paramount influence of a power altogether different from, and not governed by, any ordinary laws that have yet been discovered—a power invariably derived from pre-existing living matter and, as far as is yet known, originating in no other way—a power handed down from generation to generation without loss, but which may cease at any moment never again to be resuscitated or reproduced; and whenever this power ceases, as far as is yet known, it never undergoes conversion into any form or mode of motion and the results of its action are inimitable.

(To be continued)

RIGORS IN CHILDREN.

BY GERALD R. BALDWIN, F.R.C.S. ENG.,
LATE SURGICAL REGISTRAR TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

IN studying the subject of this paper I have employed the valuable evidence contained in the surgical case-books of the Hospital for Sick Children, Great Ormond-street. They extend over a period of seven or eight years and embrace nearly every variety of surgical disease seen in children. But although the material has only been collected from the surgical notes I have found many cases in which one of the acute specific fevers played a chief or subsidiary part. Before quoting from the collected statistics it is as well to consider with what diseases rigors are commonly associated in adults and what are the other symptoms which most frequently accompany them. Certain acute specific fevers, and more especially cases of acute pneumonia, are commonly ushered in by a rigor. When extensive inflammation advances to suppuration one or more rigors may occur. In septic poisoning (sapræmia) and septic infection (septicæmia) they are not uncommon, while they invariably accompany pyæmia. Of the accompanying symptoms pyrexia is essential; no shivering fit can be truly termed a rigor unless the temperature rises above the normal. The other symptoms depend largely on the nature of the disease; but if it be of septic origin there are generally great bodily depression, rapid, feeble pulse, dry tongue and lips, with in many instances vomiting, profuse diarrhœa, and muttering delirium. If the disease be pyæmic secondary abscesses will be present in the subcutaneous tissues, joints, or viscera. This preliminary consideration is necessary before I quote the collected cases, as many of them were accompanied by several of the symptoms I have mentioned.

Rigors occur with extreme rarity in children. Out of 130 cases rigors are only mentioned in five, while one case is said to have begun with shivering and in another frequent shiverings are recorded. The diseases selected for investigation have been chiefly of septic origin; but, in addition to these, I have included others, such as acute specific fevers beginning in the surgical wards and hyperpyrexia of doubtful origin, in which rigors may occur in adults. Roughly classifying the cases they arrange themselves into the following groups: acute abscess, cellulitis, hyperpyrexia, acute specific fevers, complications of mastoid suppuration, acute arthritis, acute periostitis, and acute epiphysitis.

I.—Acute Abscesses.

Of these there are twenty-seven cases and in only one did

Digitized by Google

rigors occur—i.e., in a boy six and a half years old, admitted for a deep abscess behind the carotid vessels in connexion with the œsophagus. This had followed an abrasion caused by his swallowing a triangular piece of pie-dish. He had vomited the foreign body soon after its lodgment, but shortly afterwards became unable to swallow. A little later he was feverish with dyspnœa and frequent vomiting. The child had a rigor when admitted and this was repeated on ten subsequent occasions, his temperature rising to 106° F. frequently during the rigors. With these symptoms there were others clearly pointing to general pyæmia, such as delirium, dry tongue, refusal of food, diarrhœa, vomiting, and extreme prostration. During his stay in the hospital he developed septic broncho-pneumonia. After death, which occurred, notwithstanding incision and drainage, fourteen days after admission, pyæmic abscesses were present in nearly all the viscera. Of the other cases there were three subpectoral, three axillary, three ischio-rectal, two tonsillar, two gluteal, two thigh abscesses, and two cases of whitlow, with one abscess dependent on necrosis of the jaw, one subdeltoid, one cervical, one popliteal, one inguinal abscess, and one in the scalp and side respectively. In one instance the abscess was probably pyæmic, while in another case there were numerous abscesses present at the time of admission. The ages of the patients varied between five weeks and eleven years, the average being about three years. In many of the children those septic symptoms with which rigors are often associated in adults were present. Thus in a case in which the abscess was associated with necrosis of the lower jaw the temperature varied between 99° and 106° and was accompanied by exhausting diarrhœa. The case eventually ended fatally. The child was two years of age. Another patient suffering from purulent ophthalmia was admitted with an abscess near the knee unconnected with disease of bone. Although this was opened and drained the case ended in death. During the illness there were severe septic symptoms, including pyrexia, vomiting, and diarrhœa. Possibly the whole process was pyæmic, infection having occurred by absorption of the purulent conjunctival discharge. A third child, three years old, was admitted with a large subpectoral abscess. She was in a drowsy condition, with dry tongue and lips and high fever, evidently resulting from septic absorption. The abscess was opened and drained, but even after this treatment the temperature remained high, and there was extensive burrowing of pus superficial to and beneath the pectorals. By counter-incisions and drainage the cavity was thoroughly emptied and the child eventually recovered after passing through a condition of extreme prostration.

II.—Cellulitis.

I have collected the notes of fourteen cases of cellulitis. In none of these are rigors mentioned, but in one child with cellulitis of the foot the disease began with a convulsion and in a second case numerous convulsions were noticed. The child was twelve months old and admitted for a scald of the thigh, the temperature being 105·8° F. Among the cases were four of submaxillary cellulitis, three of subpectoral cellulitis, two of cellulitis of the thigh, two of cellulitis of the leg, and isolated cases occurring in scalp, foot, and hand. In many of them all the symptoms associated with septic absorption were present excepting rigors. The average age of the patients was fourteen months. Three cases ended fatally.

III.—Hyperpyrexia of Doubtful Origin.

I have included two cases under this heading and in neither of these were rigors present. In one child aged two months, after excision of a large spina bifida, the temperature for two days varied between 104° and 105° F., but subsequently fell to normal, and the child made a satisfactory recovery. The second child was fourteen months old. She was admitted for a very large cavernous nævus involving the right axilla and the whole of the right arm. It was ulcerating in places at the time of admission, and subsequently the ulceration involved nearly the whole arm. The temperature rose to 108° once and afterwards varied between 101° and 104° during four weeks. With this high temperature, probably the result of septic absorption, there was frequent vomiting. Eventually under antiseptic treatment, and more especially after chlorinated soda had been applied, the temperature fell to normal and the arm eventually became covered with thin unhealthy skin, the nævus degenerating. I have included under this heading a third case, not so much because the cause of the fever was doubtful as on account of the difficulty of including it in any other class. A child aged two years, admitted for tuberculous dactylitis, subsequently developed meningitis and died. After two days' fever and drowsiness the child had one rigor. Afterwards the characteristic symptoms of meningitis manifested themselves and were verified by a post-mortem examination.

IV.—Acute Specific Fevers commencing in the Surgical Wards.

Many cases which are inclued in other classes died from one ot the acute specific fevers, but I have not thought fit to include them in this sub-division because death was probably due in a large measure to the surgical disease, though possibly accelerated by the medical complication. But I have found seven cases, five ending fatally, in which one of the acute specific fevers played the chief part. One child aged nine weeks, who was admitted for spina bifida, died from lobar pneumonia after eight days' illness, during which the temperature varied between 103° and 105° F. for eight days and was associated with persistent vomiting. A second child thirteen months old under treatment for congenital syphilis died from broncho-pneumonia. A third child eight weeks old, admitted for an abscess in the thigh, developed scarlet fever, which began with a rise of temperature to 105° and vomiting. This case ended in recovery. Another case in which death ensued is rather interesting. The child was admitted for disease believed to be pyæmia, but recovered. This was followed by pneumonia with recovery. During convalescence the child was attacked by scarlet fever. While this disease was running a fairly mild course a membranous patch, possibly the result of scarlet fever, but believed to be diphtheritic, was noticed on the fauces. It extended into the air passages and although tracheotomy was performed the result was fatal. The fifth child was admitted semi-comatose with hyperpyrexia. Dr. Barlow saw the case and considered it to be one of malignant scarlet fever. The child was isolated and died soon after admission. In a sixth case the child had acute lobar pneumonia, but recovered. In a seventh there was fatal broncho-pneumonia. In no case were rigors or convulsions present.

V.—Complications of Mastoid Disease.

Suppuration in the mastoid antrum when uncomplicated is rarely attended by rigors even in adult patients, and I cannot find one instance of rigors in children, but the disease is liable to be followed by many septic complications, such as septic meningitis, septicæmia, intracranial abscess, and lateral thrombosis. With any one of these we may expect to find rigors in adults. Now what do the statistics show to be the case in children? I have collected five cases. In two there were lateral thrombosis and general pyæmia. In one of the patients, a boy aged nine years, rigors were noticed on three occasions after the septic clot had been removed and the jugular vein tied. The child eventually recovered. In a second case ending fatally, chiefly because the symptoms were so obscure that further operative treatment was not adopted after opening and scraping out the mastoid, no rigors occurred. The child was only eighteen months of age. His temperature varied from 102° to 104° F. Throughout the illness there were frequent vomiting and profuse diarrhœa. Before death a pyæmic abscess formed in the arm. After death lateral thrombosis and general pyæmia were found. In none of three other cases, one associated with temporal necrosis, one with subdural abscess, and the third with suppurative meningitis, were rigors present, although two of the three cases ended fatally. Convulsions were absent in every case.

VI.—Empyema and Pleurisy.

In four cases, three of empyema and one of pleurisy, I cannot find any history of rigors or convulsions. The patients' ages varied from four to eleven years, the average being seven years.

VII.—Acute Arthritis.

I have collected twenty-six cases of acute arthritis. In thirteen of these the affected joint contained pus and five cases ended fatally, yet rigors were absent in every instance. Some of the cases deserve a more extended notice. A child aged eight months was admitted for acute arthritis of the knee-joint. The joint was opened and found to contain pus. It was flushed out thoroughly with perchloride of mercury

Digitized by Google

solution. Next morning erysipelas attacked the wound and eventually proved fatal. In another child aged nine years the arthritis began very acutely with vomiting, headache, loss of appetite, and sleeplessness after a fall four days previously. Incision and drainage cured the disease. In a third infant fifteen months old erysipelas attacked the wounds through which the joint was opened and washed out. The child recovered, but later secondary pyæmic abscesses necessitated amputation of the limb. This failed to prevent a fatal termination. In another case cellulitis followed the opening and drainage of the joint. The temperature was very high, rising to 104° F. on many occasions. Recovery followed numerous incisions. Another case was believed to be pyæmic in origin, absorption having taken place from a septic wound. The disease ran an acute course and ended fatally. In a child aged thirteen months arthritis of the shoulder-joint was followed by broncho-pneumonia. The child eventually recovered. Another case was followed by measles and fatal broncho-pneumonia. In only one instance were convulsions present. This occurred in a child aged twenty-five months in whom the onset began acutely with convulsions and pyrexia. Recovery followed incision, irrigation, and drainage. The ages of the patients varied between fourteen days and nine years; the average age was nineteen months.

VIII.—Acute Periostitis.

I have felt inclined to include acute periostitis and acute epiphysitis under one heading, as it seems to me that the two diseases are identical in their origin. Both appear to commence near the epiphysial cartilage and their after-course depends on whether the diaphysis or epiphysis is chiefly involved. But at present we are accustomed to classify them separately, and therefore I might confuse matters by classing the two together. I have examined the notes in twenty cases of acute periostitis. In only one of these can I find any history of a rigor. This occurred in a child aged eight and a half years who developed acute periostitis of the left tibia after receiving a kick upon that bone. The onset began acutely with fever, vomiting, and headache. One week afterwards there was swelling of the left leg preceded by a rigor. The disease was treated by a medical man who incised the swollen limb. But later the limb required amputation on account of extensive necrosis of the tibia. In another child aged three years and nine months the disease began with convulsions. The case is full of interest, not so much on this account as because of the course of the disease and treatment adopted. In addition to convulsions the onset was marked by vomiting and fever. The right leg, which had been kicked, swelled up and became intensely painful and tender. Subsequently both hips became swollen and flexed, and there was synovial distension of both elbows and wrists. The child lost his reason. He was admitted into the Hospital for Sick Children, Great Ormond-street, four months afterwards with multiple bedsores, swelling over the right fibula, and a sinus leading to exposed bone; both hips were acutely flexed, with grating on movement, the left hip being dislocated upon the dorsum ilii; his mental condition was one of idiocy. He was extremely pale and emaciated. On Aug. 26th, three weeks after admission, the greater part of the right fibula was removed as a sequestrum and the right hip was excised; on Oct. 5th the left hip was excised. On Sept. 9th a swelling was noticed over the left occipital bone; it seemed to increase when he cried, and there appeared to be a deficiency of bone at its base. On that day it was opened and proved to contain pus, but it subsequently filled again. On Oct. 15th it was opened up freely and found to be connected with a deficiency in the occipital bone leading to a cavity between the dura mater and bone, which was lined by granulation tissue; this lining membrane was scraped away freely after a large area of bone had been removed. The cavity was left open, to heal up by granulations. After three or four weeks he was sent to a convalescent home, all the wounds having healed. The bedsores had healed long previously under careful nursing and good diet. Later in the year he returned, being perfectly sound mentally, but with a recurrent abscess near the left hip. This was opened and the acetabulum found to be perforated. He is still an inmate of the hospital. I have been tempted to dwell at length on this case as it shows how severe septic infection may be in children without the occurrence of rigors. Personally I believe the whole process to have been pyæmic, although there is the alternative possibility that the disease was in part a tuberculous one following upon acute necrosis. In another child aged seven years and eight months the temperature varied between 104° and 106° F., and secondary abscesses formed in one elbow and ankle. The limb was amputated, but this failed to regard these as rigors. The patients' ages varied from six to save the child's life. In a fourth case the disease was attended by almost constant shivering fits. It is hardly possible weeks to nine years. Of the twenty cases four ended fatally.

IX.—Acute Epiphysitis.

Acute epiphysitis is one of the most common and most fatal of the septic diseases of children. Of twenty-one cases recorded in our case books during the last seven or eight years no less than twelve ended in death. However, some were complicated or followed by other diseases which helped in the fatal result. Thus one case, though typically acute in character, was of tuberculous origin, and death was due to general tuberculosis. Two other children died from erysipelas. In one boy aged four years the diagnosis was not verified by post-mortem examination. Five days before admission he had twisted the right leg. Next day he suffered from pain, swelling, and tenderness of the right thigh, with fever, loss of appetite, and vomiting. On the day before admission he became delirious. When admitted he was dusky, with a temperature of 105° F. (106° later), very feeble pulse, and rapid respirations accompanied by retraction of the intercostal spaces. He was extremely restless and delirious, with dry lips covered by sordes. There was much bronchitis in both lungs, with dulness behind and very clearly conducted sounds suggestive of broncho-pneumonia. Nothing was heard over the præcordial area pointing to pericarditis. The right thigh was acutely flexed, its upper third was swollen and extremely tender; fluctuation was present above and behind the great trochanter. The joint was distended. Clearly the boy was suffering from acute septic poisoning, the result of one of three things—acute epiphysitis of the femur, acute arthritis of the hip-joint, or possibly acute periostitis of the ilium. He was immediately operated on and an abscess found, but owing to his great exhaustion the operation was shortened as much as possible, so that the exact origin of the disease was not discovered. The child died on the same evening and his parents refused to allow a post-mortem examination. Of the other fatal cases, one child died from general pyæmia following epiphysitis of the upper end of the tibia, two from secondary septic meningitis, and five from septic infection and exhaustion, death being preceded by suppurative arthritis in two instances. Of the nine cases that recovered, in two there was secondary arthritis requiring incisions into the joint and drainage; in one instance the disease was bilateral, affecting the lower ends of the femora and accompanied by double popliteal abscess. It appeared to be pyæmic in origin. The other cases ended favourably after incision and drainage. The children's ages varied from four weeks to ten years. In no case were rigors recorded, and convulsions were present only in those cases where death followed septic meningitis.

I have only one more case to record. A child aged six years, who had been sent to the convalescent home after excision for hip disease, returned to the hospital with a high temperature and acute pain with tenderness in the left side. On the night of admission she had a genuine and severe rigor which was seen and verified by the house surgeon. The temperature remained high for a few days and then fell to and remained normal. A few days after she passed some pus in her urine, and continued to pass a small quantity with uric acid crystals at first (the urine being acid) and triple phosphates later, the reaction becoming alkaline. No enlargement of either kidney was found. In this condition she was again sent to the convalescent home and she was there when this was written. I have not attempted to classify her disease, probably she has early tuberculous pyelitis.

From the statistics I have collected and the cases quoted I think we may conclude that rigors are extremely uncommon in children, even in diseases which are acutely septic in character. On the other hand, convulsions are also uncommon in children. In 130 cases I have only found five in which rigors occurred—i.e., once in a case of lateral thrombosis, the child being nine years old; once in a boy aged six and a half years, who died from pyæmia following acute abscess; once in a case of tuberculous meningitis occurring after tuberculous dactylitis in a child aged three years; once in a boy aged three years, who had acute periostitis of the tibia; and once in a child aged six years, the rigor being of doubtful origin. Two of these cases ended

Digitized by Google

fatally. In five cases there was a history of convulsions, once in a child aged eleven months with cellulitis of the foot; once in a case of cellulitis of the thigh and bronchopneumonia, the child being one year old; once in a child aged two and a half years suffering from acute arthritis; and twice in children with acute periostitis, aged respectively two years and nine months and three years and nine months. The majority of the cases I have collected might have been accompanied by rigors in adults. I have gone so far as to risk rendering this paper tedious in order to accentuate the many other symptoms which seemed to point clearly to septic infection and in many cases to pyæmia. If, as is generally supposed, the shivering in a rigor is caused by contraction of the superficial arterioles induced by irritation of the vaso-motor centre by various poisons in the blood, the cause for the extreme rarity of rigors in children is probably to be found in a less perfect development of that centre in them than in adults. The frequency of hyperpyrexia from comparatively trivial causes is another clinical fact which lends its weight to this suggestion. I think I may safely conclude from these statistics: (1) that rigors are very rare in children and almost unknown under three years of age; and (2) that convulsions very rarely take the place of rigors even in infants.

Rigors are not of very great clinical value in studying the diseases of childhood. Before the age of seven or eight symptoms apart from signs can never assist so clearly in diagnosis as in older patients. As I have already said, hyperpyrexia may follow upon trivial causes. The facial expression, manifestations of pain, and even the pulse itself seldom give the surgeon perfectly reliable information. But rigors may mislead him more than any other manifestation of disease. As a rule they point to severe infection and if oft repeated generally to septic infection, but their presence or absence rarely assists in differential diagnosis. To take one instance from among many. In an adult with a profuse and fœtid discharge from the ear the occurrence of rigors, especially if associated with other symptoms such as vomiting and optic neuritis, points to lateral thrombosis. Yet I have already mentioned two cases of that disease in young children, in one of which rigors occurred before and after ligature of the jugular vein, while in the second there were neither rigors nor convulsions throughout. Since writing the foregoing I have found two cases of mastoid suppuration in which rigors were associated with a very high temperature, vomiting, and optic neuritis. In both cases the jugular vein was exposed, but in neither case was a septic thrombus found in it or in the lateral sinus. One of these cases occurred at the Hospital for Sick Children, Great Ormond-street; it was not included among my cases as the child was under the care of a physician and treated throughout in the medical wards. The second patient was treated at St. George's Hospital. Another instance is general pyæmia from other causes. I have quoted from the notes of many cases of children who died from this disease, and in only one of them were rigors present. The same remarks apply to all the cases in which rigors did occur. They were isolated instances from among many similar cases of equal severity. Why one child had rigors and another had not it is impossible to say. The great fact that these cases appear to point out is that in diagnosis only a minimum amount of weight can be given to the absence or presence of rigors in children.

King-street, Portman-square, W.

VACCINATION GRANT.—Mr. Charles Wightwick Pitt, of the first district Malmesbury Union, has for the fourth time received the Government grant for successful vaccination.

DIPHTHERIA AT GILLINGHAM.—Diphtheria has reached an alarming stage at Gillingham, near Chatham, 33 deaths having been chronicled in a population of less than 30,000 persons during the present year. We notice that the Registrar-General states that 21 deaths from the disease were registered in the place in the first three months of this year, these figures themselves being equal to an annual rate of 3 per 1000; whilst the addition of 12 deaths since that period gives evidence of increase of a sort to call for serious inquiry. The hospital is said to be full of patients, and removals thereto have to be sent away at the end of three weeks to make room for other claimants for beds. It has been decided by the district council to purchase two tents at a cost of £90 and to erect them in the hospital grounds.

A CONTRIBUTION TO THE OPERATIVE TREATMENT OF MALIGNANT DISEASE OF THE LARYNX, WITH SPECIAL REFERENCE TO THE DANGER OF CANCEROUS WOUND INFECTION.

BY H. LAMBERT LACK, M.D. LOND., F.R.C.S. ENG.,

ASSISTANT PHYSICIAN TO THE THROAT HOSPITAL, GOLDEN-SQUARE; SURGEON TO THE THROAT AND EAR DEPARTMENT OF THE CHILDREN'S HOSPITAL, PADDINGTON-GREEN, ETC.

THE object of this paper is, first, to direct special attention to the possibility of the dissemination of cancer by means of direct transplantation as distinguished from dissemination by means of the blood and lymph channels; secondly, to the danger of infecting a wound with cancerous material in operations for malignant disease generally; and, thirdly, to consider the importance of these facts in relation to local recurrence after operations for malignant disease of the larynx. I shall discuss each of these subjects separately and shall commence by quoting some illustrative cases I have observed or have found in medical literature bearing on each point. Thus Ebert has recorded a case in which a secondary epitheliomatous growth appeared on the tip of a long uvula which was in contact with a similar ulcerating growth in the larynx. In another case two epitheliomata were observed on opposite and corresponding parts of the same larynx which would come in contact on phonation, the intervening tissues remaining healthy. In a third case of epithelioma of the larynx a secondary deposit took place on the site of an abrasion on the lower lip, and there being no other secondary deposits of malignant disease the reporter of the case concluded that this secondary growth arose from direct transplantation of the cancerous epithelioma derived from the primary growth and conveyed to the lip by means of the sputum or saliva.

Similar cases can be quoted with regard to cancer in other regions. Thus Ebert in his Inaugural Thesis relates the following instances: 1. A case in which a carcinoma of the cervix uteri gave rise to a secondary deposit on the left vaginal wall. The body of the uterus was dragged over to the right by an old adhesion, the cervix was abnormally long and the affected parts were thus maintained in contact; the cauliflower-like growth on the cervix fitted exactly into the crater-like ulcer of the vaginal wall. The roof of the vagina was free from disease. 2. A second case, almost identical with the above, in which there was prolapse of the uterus, a carcinoma of the cervix and a secondary growth on the vaginal wall in contact with it, the intervening tissues remaining healthy. 3 and 4. In two cases a malignant growth limited to one side of the vulva was followed by a similar growth on the parts in contact on the opposite side. 5. A case in which the anterior and posterior walls of the vagina were affected with malignant disease, the growths being in contact and the intervening tissues being sound. 6. A case observed by Bergmann of epithelioma of the upper and lower lips. 7. A case of epithelioma of the side of the tongue and of the part of the cheek in contact with it. 8. A case of carcinoma of the stomach in which there was found a similar carcinoma on the surface of the liver in direct contact with, but not adherent to, the growth in the stomach. With the two previously quoted laryngeal cases one thus finds in all ten cases of transplantation of malignant disease, in all of which the affected parts were in direct contact and in all the intervening tissues were free from disease.

In another series of cases the secondary growth has occurred at a distance from the primary disease, as in the larynx and lip case above noted. Such cases are the following, quoted mainly from the theses of Erbse and Ebert. 1. A case observed by Kaufmann of cancroid of the skin of the right hand lasting five years, and for one and a half years a similar tumour had been noticed on the conjunctiva of the right eye. The patient had epiphora and frequently rubbed the affected eye with his hand. 2. In a case of carcinoma of the upper jaw and tongue reported by Klebs a similar growth was found in the stomach. 3. A case of epithelioma of the œsophagus in which a similar growth was found in the stomach.

Digitized by Google

4. A case of carcinoma of the tongue in which a similar growth was found in the duodenum. 5. A case of epithelioma of the lower part of the œsophagus in which secondary growths were found in the intestinal tract. 6. A case of epithelioma of the larynx with a secondary deposit in the left bronchus. 7 and 8. Two cases of carcinoma of the œsophagus ulcerating into the larynx and trachea in which secondary deposits occurred in the lower lobes of both lungs, chiefly in the walls of the smaller bronchioles, and which apparently arose from deposits of inhaled particles of the disease. 9. A case of carcinoma of the pelvis of the kidney, followed by carcinoma of the bladder, the ureter remaining healthy. 10. To this list may possibly be added the extremely interesting case reported by Gross in which a man contracted carcinoma of the penis from his wife, who was suffering from carcinoma of the cervix uteri. The disease of the penis and cervix showed the same structure—viz., glandular carcinoma, and it forms an apparently unique instance of direct transmission of cancer from one individual to another. These cases make in all twenty-one, to which other less definite cases could be added, and I have probably overlooked many; but enough I trust has been said to show that this method of spread of cancer does occur, somewhat rarely it is true, although in medical literature in England at any rate it has attracted very little attention. But I wish in this paper to deal more especially with cases in which the dissemination has occurred as the direct result of an operation undertaken for the relief or cure of the disease, instances of which I believe are by no means rare. I may just briefly summarise the following cases which have come under my own notice. A man aged about fifty years was admitted into the Golden-square Hospital under my care in December, 1894. He had enlarged glands of uncertain nature on both sides of the neck, and as they were growing it was decided to remove them. On one side they were carefully removed in one mass with the surrounding tissues, and on macroscopic section appeared caseous and breaking down and were considered to be tuberculous. The other side was now rapidly dealt with, as the patient was taking the anæsthetic very badly, and one gland was unfortunately burst during its removal. The débris extruded from it was carefully washed away and the wound well irrigated at the end of the operation, but no exceptional precautions were taken. The first side operated on—the larger mass of glands—healed rapidly and well and gave no subsequent trouble. The wound on the other side never healed properly; there were from the first some swelling and a considerable amount of watery flaky discharge. In about three weeks the patient was allowed to go out of hospital. There was still a small sinus discharging a small amount of thin, flaky material and some ill-defined swelling on that side of the neck. The glands on microscopic examination proved to be carcinomatous, and two months later the whole side of the neck, from the mastoid process and lower jaw nearly to the clavicle, was a huge, brawny, indurated mass of malignant disease. There were now also definite signs of a malignant growth in the lower part of the pharynx springing up from behind the arytenoids. An almost identical case has occurred in the practice of Mr. Watson Cheyne. A mass of recurrent epitheliomatous glands on either side of the neck was removed, on one side cleanly, and here there was no subsequent trouble, but on the other side one gland burst during removal and was subsequently rapidly followed by diffuse carcinomatous infiltration of the whole side of the neck. Another interesting case was also observed in King's College Hospital under the care of Mr. Watson Cheyne. The patient was a man suffering from recurrent sarcoma of the lower jaw. After a part of the jaw had been removed with an adherent submaxillary lymphatic gland it was considered advisable to perform tracheotomy. Recurrence took place in a few months in the scar of the tracheotomy wound. After its removal the malignant mass had been cut into and the tracheotomy wound was undoubtedly infected by the hands or an instrument or sponge used in the earlier part of the operation. A fourth case I have seen was that of a woman in the Hospital for Diseases of the Throat, Golden-square, W., suffering from carcinoma laryngis, and on whom complete extirpation of the larynx was performed by Dr. Bond. After the usual vertical incision another cut was made at right angles to it along the lower border of the hyoid bone outwards to the sterno-mastoid. Before removal of the malignant mass the larynx was split vertically to see the extent of the growth, which was in this way cut into. About eight months later recurrence occurred which at first sight seemed to be in the glands, but which on removal was found to be in the scar at the extreme outward limit of the above-mentioned transverse incision. In this case, also, it seems certain that the growth was transplanted to the part by the operation, division of the larynx and growth having given ample opportunity of infecting the instruments &c. A similar case operated on by Bull of New York is on record in which, after removal of an epitheliomatous larynx which had been cut into during the operation, recurrence shortly occurred in the scar of the tracheotomy wound. The details of this case are, however, a little indefinite as to the mode of infection, and it may have been a direct extension of the disease.

A few cases of transplantation arising in connexion with cancers in other regions may now be briefly mentioned. An undoubted case of this kind is one operated on by Wölfler in which pylorectomy was performed for malignant disease, and nine months later recurrence was found in the scar of the wound in the abdominal parietes. This was removed, but recurrence took place in the glands in the groin.

The following cases are taken from Ebert's thesis:—A case observed by W. Thorn of carcinoma of the cervix uteri. The vagina was very narrow and had to be slit in both directions to allow sufficient room for vaginal hysterectomy. Recurrence of the disease occurred in the incision near the rectum. Two cases in which paracentesis was performed for malignant disease of the peritoneum and in which a secondary growth appeared in the muscles of the abdominal wall at the seat of puncture. In both cases the peritoneum immediately underlying and surrounding the puncture wound was unaffected. A precisely similar case in which a secondary growth appeared at the site of puncture of the abdominal wall for ascites due to malignant disease of the liver. A case observed by Von Sippel of malignant ovarian cyst which was burst during its removal. Seven months later there was ascites, and hard lumps could be felt in the abdominal cavity. A second laparotomy was performed and the peritoneum was found extensively studded with malignant nodules, but there was no recurrence at the site of removal of the ovary and no malignant disease of any other abdominal organ. The peritoneum over the old abdominal scar was healthy, but each of the deep stitch tracks was the site of a tumour varying in size from a pea to a cherrystone. These little tumours formed a double row, and on microscopic examination proved to be cylindrical-celled carcinomata. A case related by Gross of tumour in the rectum, in which after removal recurrence occurred in the skin wound. Kraske reports similar cases in which after excision of the rectum recurrences have occurred in the skin wounds near the anus. A case observed by W. Thorn of cancer of the uterus, in which the growth did not reach as far as the external os, and in which, after total hysterectomy, recurrence occurred as a projecting mass in the scar of the vaginal roof. (This case appears capable of being explained differently.)

In almost all the thirty-five cases quoted above dissemination by the blood or lymph stream seems an extremely improbable explanation of the observed clinical data, nor can the recurrence in the large majority of the operation cases be possibly due to a local incomplete removal. The latter cases seem to me a quite sufficiently convincing proof of the point to which I especially wish to draw attention—namely, the great danger we run in infecting our patient with the very disease we are endeavouring to eradicate if at any time during the operation we cut into the affected tissues or infect our hands, &c., with it. Some considerations on the above cases tend to show that this danger is even greater than may at first sight appear. Thus no less than four undoubted cases have come under my own observation in the last four years. Again, it seems possible, even probable, than in many cases a local recurrence in the scar is really due to cancerous wound infection, although in the great majority of such cases it is obviously impossible to exclude instances of recurrence due to imperfect removal, however thoroughly the operation may appear to have been done. It is almost only in the exceptional cases where an implantation growth has occurred in a wound made at a distance from the primary seat of the disease that we can exclude positively other channels of dissemination. The scarcity of such cases met with in medical literature may be reasonably ascribed to the fact that when they have occurred they have been for the most part

Digitized by Google

looked on as local recurrences. Such cases would probably not be considered worth publishing, and, further, my search has been but a very limited one. In the two cases of malignant glands in the neck above described the subsequent course of events leaves no room for doubt as to the cause of the dissemination of the disease, and it is suggestive as showing danger in wounds which we completely close that infection occurred in the only two cases in which I have seen carcinomatous glands burst during their removal. Further, in these cases not a simple recurrence occurred in the scar, but the whole wound and side of the neck were involved in one huge mass, and similarly in the case of laparotomy for malignant ovarian disease almost every one of the deep stitch tracks became the site of a malignant growth. In a wound left open or packed as in most laryngeal operations the danger is probably not nearly so great, any epithelial cells left in the wound being washed away with the discharge or removed with the dressings; yet many of the cases quoted above show that the danger even in these cases is a very real one.

In some respects malignant disease of the larynx appears eminently suitable for curative operations, general dissemination of the disease being an extremely rare occurrence, and infection of the glands in cases of intrinsic carcinoma being an also rare and, when it does occur, a very late event. Thus the disease remains local either throughout its course or at any rate for a very long time; and as we should expect from this we find that in operations on the larynx excluding the immediate risks local recurrence is the great danger to be feared. The statistics of these operations, those of Wasserman, of Pinçonnet, and a large number collected by myself of operations performed in the last six years all agree closely on this point. Excluding the cases in which death occurred soon after the operation or in which the result up to one year is not reported, we find approximately 65 per cent. of local recurrences, as compared to 30 to 35 per cent. of cases well one year or more, of which latter about half, that is 15 per cent. of the whole, were definite cures. Thus it is obvious that although in recent years much has been done to improve the technique of these operations and lessen the immediate mortality, much more must still be done to improve the prospect of cure of the survivors before we can urge our patients to submit to the still considerable risks of the operations, especially that of complete extirpation. In the operation of excision of the larynx, total or partial, or of thyrotomy it is a very usual plan to split the thyroid cartilage early in the procedure so as to inspect the exact nature and extent of the disease. This is, no doubt, a very convenient procedure and is quite unobjectionable in those cases in which, so far as we can determine, the anterior part of the larynx is free from disease; but where the affection spreads across the mid-line in front it opens the door to the risk of infection, and is, I venture to submit, one of the causes of the very large number of local recurrences. In the following case, occurring in my own practice, to avoid this danger a modification of the usual method of performing thyrotomy was successfully adopted.

A woman aged sixty years came to the Hospital for Diseases of the Throat, Golden-square, in September, 1894. She complained of hoarseness commencing about three months before, and gradually increasing until the voice was reduced to a hoarse whisper. There were no other prominent symptoms. On laryngoscopic examination a white cauliflower-looking growth was found springing apparently from the edge and under surface of the left vocal cord and anterior commissure. There was some surrounding hyperæmia. The arytenoids moved well, but the anterior halves of the cords were apparently fixed. The larynx was cocainised and an attempt made to remove a piece of the growth with the forceps. This failed, but a large piece was easily removed with the cutting curette. A series of sections was at once cut and left no doubt the tumour was a squamous-celled epithelioma. The patient was at once admitted to the hospital, and on Sept. 22nd the following operation was performed. After preliminary tracheotomy and introduction of Hahn's cannula the larynx was exposed by the usual vertical incision. The soft parts were then dissected off in front of the crico-thyroid membrane, the cricoid cartilage and lower part of the thyroid cartilage going well back on either side. A small piece of the anterior ring of the cricoid cartilage was then removed so as to, as it were, enlarge the crico-thyroid space, and the larynx opened by dividing transversely the mucous membrane as low down as it could now be reached. By curved scissors this opening was enlarged upwards well back on the right side. These incisions were guided by the previous knowledge obtained by the laryngoscope of the extent of the growth, and were planned so as to keep at a sufficient distance from it. Through this opening one could now easily see the exact limits of the growth. A semicircular piece of the lower part of the thyroid cartilage was next removed and the mucous membrane and soft parts detached for a short distance all round. All this exposed and detached mucous membrane, including the whole of the crico-thyroid membrane, was then clipped away in one piece. The part removed included more than half the right and nearly the whole left vocal cord, and was nearly circular, with a growth as large as a sixpence in the centre, surrounded everywhere with a margin of at least three-quarters of an inch of healthy tissues. This method of operating, although apparently inconvenient, was by no means difficult or troublesome to carry out. The usual after-treatment was adopted, the patient could take both solids and fluids by the mouth after the first day, and her progress was uninterrupted. The patient was discharged with the wound soundly healed on Nov. 3rd, but in December it was considered advisable to re-insert the tracheal cannula. The patient still (March, 1896) remains well, but retains the tube.

Where the whole larynx is involved or complete extirpation is considered necessary it should be removed in one piece, and the method recently adopted by many foreign surgeons, such as Perier, Poppert, Cohen, Swain, &c., seems to be the best hitherto described. In this operation the larynx and trachea are first well cleaned, the trachea is then raised from the œsophagus and cut right across. The upper end of the windpipe is then stitched to the skin, a tampon-cannula tied in, and in this way is completely shut off from the wound. The larynx is now detached from the œsophagus from below upwards until the arytenoids are reached, when the pharynx is opened. The larynx is now freed at the sides and in front well beyond the disease and removed. If the arytenoids are involved the complete removal of the mucous membrane covering them is rendered absolutely necessary if we wish to avoid an almost certain recurrence, and no attempt should be made to peel it off on the posterior surface, as is often done. The large wound into the pharynx should now be completely closed in the manner recommended by Rotter. The cut edges of the mucous membrane are first brought carefully together with fine catgut sutures, then the deeper structures, layers of muscles, &c., are brought across to support this, and finally the skin flaps are brought across and stitched in position. Thus the large gap is efficiently closed and the after-treatment becomes a very simple matter. Rotter's patient was seventy-two years of age, and complete extirpation left a very large wound in the pharynx, yet he could swallow easily and without pain after the first day, was allowed up on the seventh day, and had gained six pounds in weight in three weeks after the operation. In extensive operations on the throat the rapid restoration of the power of swallowing is of the greatest importance; it is the best safeguard against septic lung complications, for if swallowing is impossible, mucus, saliva, discharges, &c., gather in the throat and trickle down into the trachea in spite of the patient's efforts to cough. In such cases we must of course retain a Hahn's cannula or other efficient plugging of the windpipe until the power of swallowing has returned, but this is an obviously inferior method to the one above described. Where only one side of the larynx is involved thyrotomy or hemi-laryngectomy may be of course performed in the usual way, the disease being in such cases removed in one piece without cutting into it. Where, however, the growth of the larynx occupies or impinges on the anterior commissure, and thyrotomy or some partial excision is determined upon, precautions should be adopted, as in my own case, to avoid cutting into the growth and infecting the wound, and in any case in which a malignant growth is unexpectedly cut into the wound should be thoroughly cleaned. Cauterisation is probably the only reliable method of destroying the infective cells, and a fluid cautery such as undiluted carbolic acid is the most likely to thoroughly reach all parts of the wound and leads to the least subsequent trouble.

To sum up, it seems very advisable that in all cases of malignant disease the growth should be removed in one piece, all incisions being made in healthy surrounding tissues, and where this has not or cannot be done that the wound

Digitized by Google

should be cleansed afterwards by cauterisation. This probably applies equally to cancer in all regions of the body, although, in so far as I know, in no region is the growth so frequently cut into during the operation as it is in operations on the larynx. Throughout this paper I have almost unavoidably used the term infection although none of the cases I have brought forward point in any way to cancer being an infectious disease, that is, in the ordinary sense of a virus; rather they all point to the dissemination having taken place by a direct transference of the cancer cells. Finally, I have to express my thanks to Dr. J. W. Bond and Mr. Watson Cheyne for kindly allowing me to make use of some of their unpublished cases.

A SUCCESSFUL CASE OF LAPAROTOMY FOR COMPLETE INTESTINAL OBSTRUCTION SUBSEQUENT TO AN ATTACK OF PERITONITIS.

BY A. C. BUTLER-SMYTHE, F.R.C.P., F.R.C.S. EDIN.,
SURGEON TO THE GROSVENOR HOSPITAL FOR WOMEN, AND SURGEON TO OUT-PATIENTS AT THE SAMARITAN FREE HOSPITAL FOR WOMEN.

IN April, 1895, I received an urgent message from Dr. Wright and Mr. Mackenzie of Romford, Essex, asking me to go down to explore the abdomen of a young man aged twenty years who had had complete intestinal obstruction for a week and was then vomiting stercoraceous matter. On my arrival the following history was elicited. About six weeks previously, after a long day's hunting, during which the patient went without food and got drenched twice, he complained of pain in his stomach and fainted on reaching home. He went to bed and had a hot drink, and on the following morning sent for Mr. Mackenzie, who found him feverish and with all the symptoms of peritonitis. The patient had a bad time of it for some weeks, though eventually he pulled through and seemed to be getting well, but on the Friday before my visit he suddenly became worse, the pains returned, the abdomen swelled, and vomiting occurred. For about a week there had been no proper action of the bowels, and for two days little or no flatus had passed. Rectal injections had brought away a small amount of hard fæces, but his sufferings continued and he was rapidly losing strength. On examination I found his abdomen much distended, tympanitic, and exceedingly tender. His temperature was 99° F., the pulse 100, the tongue moist and white, the face flushed, and the countenance anxious. The urine was scanty and dark, and the vomited matter was bilious and offensive but not fæcal. Judging from his stature the patient must at one time have been a muscular youth, but at that moment he was looking very ill and haggard. During his long illness he had been lying on a feather bed, and as a consequence had contracted a large bedsore over his sacrum. Gurgling was distinctly heard and felt in the line of the colons, and the dilated coils of small intestine could be seen moving beneath the abdominal wall. There was no special tenderness over the situation of the ileo-cæcal valve, but the patient complained of severe spasmodic attacks of pain in his abdomen, and particularly referred to a spot about two inches below, and to the left of, the umbilicus, where the pain was continuous. He also stated that soon after swallowing fluids he experienced agonising pains in the pit of the stomach. On exploring his rectum the finger impinged on a large mass of fæcal matter very high up; I therefore ordered a copious enema of olive oil, turpentine, and soap-and-water, which brought away a large amount of hard, light-coloured fæces. This treatment relieved his pain somewhat and the vomiting ceased, but the abdomen remained distended and tender. As the hour was late and the patient's symptoms were now less severe it was decided to leave him for the night in the hope that some improvement might take place before morning. He was given twenty drops each of tincture of belladonna and opium and another enema was ordered to be administered at 7 A.M. In the meantime it was arranged that I should hold myself in readiness to operate if the symptoms again became urgent. For the next twenty-four hours the patient seemed to be much better and had no sickness. The enema had brought away more hard fæcal matter and the abdominal pain was bearable. The day following he was not so well and at night became very ill. Early next morning I had a telegram asking me to come at once. On arrival I found the patient in great pain and praying to be relieved. His abdomen was immensely distended, the lower portion being discoloured and œdematous. The vomit was distinctly fæcal, the tongue was brown and dry, and the pulse was 140 and thready. No flatus had passed for twenty-four hours and the patient was in a most critical condition. I put the matter very plainly before him and his father, and they at once consented to any operative measures that would give the slightest chance of life. The patient was then carried into an adjoining room, where there was a better light and where everything was in readiness for the operation. Taking into consideration his exhausted condition and the probability of a lengthy operation, Mr. Mackenzie decided to give the A.C.E. mixture and the result was all that could be desired, the patient rapidly getting under its influence and remaining completely anæsthetised whilst on the table. Mr. Wright took charge of the sponges and rendered most valuable assistance. Fully expecting to find the chief cause of trouble at the painful spot so often referred to by the patient I opened the abdomen immediately below the umbilicus, and it was fortunate that I did so, for on introducing my finger I detected a coil of intestine flattened out and adherent across the middle line just below my incision. This was detached and the opening prolonged downwards to the extent of five inches. The small intestines were enormously distended, injected, matted together, and covered with flakes of lymph. On passing my hand into the abdominal cavity I found that it was impossible to distinguish between the large and small intestines, and therefore, though the case seemed hopeless, I proceeded to separate the coils, beginning with the portion just detached. Bit by bit the adhesions were broken down, the intestine released and brought through the wound, until the greater part of the jejunum and ileum lay outside the abdomen. The coils were protected by flat sponges and towels wrung out in warm carbolic lotion. I then carefully examined the large intestine, and on reaching the transverse colon felt a band of adhesion almost strangulating it. This was caught with forceps in two places and divided between. On passing my finger along the descending colon another similar adhesion was found, and on dividing it the flatus rushed through the intestine and dilated it enormously. The divided ends of the adhesions were then tied and the forceps removed. The separated coils of intestine were next examined and several bleeding points secured by ligation and the torn peritoneal surfaces brought together by suture. An unlooked-for impediment now presented itself, for on attempting to return the intestines it became evident that the abdominal cavity could not contain them in their distended condition. A flatus-tube was passed into the rectum and some gas escaped, but not enough to make any appreciable difference in the size of the gut. I therefore punctured the intestine in three separate coils and let out a quantity of flatus, each puncture being closed with a Lembert's suture and well washed with corrosive sublimate solution. Still the intestines could not be replaced owing to the accumulation in the colon. I therefore pulled the descending colon forward, and having isolated a portion of it and protected the peritoneal cavity, I incised it longitudinally to the extent of half an inch and let out a great quantity of gas and some liquid fæces, thus reducing the distension considerably. The incision was well cleansed with corrosive solution and then closed with four Lembert's sutures, and after another careful washing the intestine was replaced. The sponges were then removed and the coils of small intestine returned into the abdominal cavity, which in its turn was subjected to a considerable amount of cleansing with sponges. Finally the abdominal wound was closed with silkworm-gut sutures and dressed with iodoform gauze over which a large pad was placed, the whole being kept in position by strapping. The patient was

Digitized by Google

then put into bed and placed on a water-cushion. Considering the severity of the operation, which had lasted two hours, he showed but little signs of collapse although his pulse was very rapid—140. He was sick once, and as the vomit was distinctly fæcal the prognosis seemed extremely grave. However, no bad symptoms supervened, and the immediate result of the operation was most satisfactory. There was no return of the sickness, and he had some refreshing sleep. Flatus passed freely next morning, the abdomen became flat and the pain and tenderness disappeared. The tongue rapidly cleaned, the pulse, which had been 140, gradually dropped ten beats each day, and the temperature kept below 100°. On the ninth day I removed all the sutures, and from that date his convalescence was uninterrupted. By the end of the third week the bedsore had healed and the patient was out of bed on a sofa. He is now in perfect health, rides long distances on a bicycle, can walk miles at a stretch, and enjoys a day's shooting or riding. The after-treatment and nursing were admirably carried out, and it gives me much pleasure to acknowledge the valuable services of Dr. Wright and Mr. Mackenzie, who by their unremitting care and attention brought this case to such a successful issue.

Remarks.—The condition of the abdominal contents revealed during the operation fully justified, in my opinion, the extreme measures adopted. Had I been contented with detaching and liberating the portion of adherent intestine first disclosed, the operation would have been a miserable failure and I should have been discredited. Previously to this operation I had never attempted to attack such an amount of intestinal adhesion, nor had I seen or read of a case where most of the intestinal tract being adherent the adhesions were systematically broken down and the several coils separated and released. In this instance it was either certain death to the patient from obstruction or the risk of collapse from a severe and tedious process of intestinal manipulation. With regard to the intestinal adhesions their extent and degree may be imagined from the fact that the whole length of intestine liberated and withdrawn from the abdominal cavity was raw and bleeding, the peritoneum being in places stripped off, leaving the muscular structure exposed. A few remarks relative to the several forms of obstruction dealt with in this case may not be out of place, and therefore I shall enumerate them in the order in which they appeared: (1) intestine adherent to the abdominal wall; (2) volvulus; (3) omental band constricting the transverse colon; (4) peritoneal band binding back the descending colon; and (5) impaction of fæcal matter. Any one of these obstructions would probably have proved fatal if overlooked, which shows clearly how essential it is that the operator should be perfectly satisfied that the whole intestinal tract has been investigated before closing the abdomen. The first obstruction met with was due to a coil of intestine being adherent across the middle line to the extent of three inches. This portion was flattened out and completely obstructed by pressure of another coil, distended and adherent to it. The second form of obstruction was caused by the twisting of several distended and adherent coils. I have used the term "volvulus" for the want of a better one. The third was due to a thick twisted piece of omentum attached high up on the abdominal wall close to the diaphragm. It was buried in the transverse colon, almost severing it and completely constricting its canal. Curiously enough this was the only portion of the omentum seen during the operation. The fourth obstruction revealed a band of adhesion, probably peritoneal, which was attached to the left side of the abdominal wall and dipped down towards the mesentery. The colon was so tightly bound down by the band that on either side of the constriction the intestine bulged out and the band had to be divided on the finger-nail in the depths of the abdominal cavity. The impaction of hard fæcal matter was most likely induced by the administration of opiates at the outset of the symptoms. There seems to be a general opinion among surgeons that extrusion of the intestines is always to be avoided in abdominal surgery. Over and over again I have heard it stated where death had ensued subsequent to an operation that the death was directly due to shock from exposure and chilling of the intestines. Now the term "shock" has served to cover many a surgical error, but I doubt if extrusion of intestines, properly and carefully managed, adds much to the danger of an abdominal operation. So far I have never hesitated to withdraw as much intestine as was necessary to clear the field in cases of hæmorrhage or obstruction, and I have never had to regret doing so. Every precaution must, of course, be taken to keep the extruded intestine warm and completely covered. Such is my opinion at the present moment, but I am open to conviction. In this instance manual exploration of the abdominal contents would have been useless without the aid of visual examination and extrusion of the intestines, and I do not envy the surgeon who attempts to complete an operation for obstruction while relying on his sense of touch alone, particularly if the intestines be adherent and distended.

Now comes a very pertinent question. Ought one to attempt to replace the released intestines in their distended condition, or should the contents be evacuated before returning them into the abdominal cavity? Dr. Greig Smith teaches that "no case of intestinal obstruction is properly concluded until the distended bowels are relieved of their contents." In the case under discussion it would have been extremely hazardous to attempt replacement by pressure, knowing the extent of injury to the released intestine, which was immensely distended with gas and fluid fæces. The only question which arose was whether to puncture with a trocar or to incise the distended intestine. With regard to the choice between puncture and incision of distended intestine, my experience so far would go to prove that both may be necessary where the accumulation is large, and that neither method can do much harm if the proper precautions be observed in the sewing up and disinfecting of the injured gut before returning it into the abdominal cavity. Incision, however, seems to me to be preferable to puncture, inasmuch as the former makes a clean cut and gives more room for the exit of fæcal matter, whereas the latter makes a punctured or jagged wound, and the cannula frequently becomes obstructed and has occasionally an awkward way of suddenly twisting round with each successive rush of flatus, and may even be jerked out of the intestine unless carefully held in position, while at the most only gas and liquid fæces can escape through it. In any future operation I should be inclined to incise and evacuate at a much earlier stage, as such a procedure would give more space for manipulation.

Brook-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

FATAL CASES OF POISONING BY ORDINARY SORREL (RUMEX OXALIS).

BY GEORGE G. FLEMYNG, M.D. DUB.,
MEDICAL OFFICER OF THE FIRST DISTRICT OF ELY UNION.

THE following cases are of interest as I have been unable to find any recorded instance of fatal poisoning from this plant, which is extensively used in salads, &c. The active principle in the ordinary "dock sorrel" is binoxalate of potassium, which under the names of "salts of sorrel" or "essential salt of lemons" is extensively used for bleaching purposes and which has proved fatal, being mistaken for cream of tartar.

Two sisters, aged respectively six and a half years and five years, were brought to me about 10 A.M. on June 5th. The history was that about six o'clock the previous evening they had been sent to get milk at a neighbouring cottage, to reach which they had to cross some fields. They returned and told their mother that they had eaten a quantity of sorrel leaves. They then had a meal consisting of tea, bread-and-butter, and cake. Both children vomited during the night, and as this continued they were brought to me. They both presented the same symptoms, which were vomiting of a greenish-coloured fluid, deep stupor, and collapse. The pupils were dilated; the tongue was moist, somewhat swollen, and not coated with fur; the extremities were cold and clammy; the pulse was very feeble, being 120 and 106 respectively, the respirations were shallow and sighing, and the temperature was subnormal. There was neither pain nor diarrhœa. The symptoms presented the curious properties both irritant and narcotic which are characteristic of poisoning by oxalic acid and the oxalates. Owing to the condition I thought it inadvisable

Digitized by Google

to administer emetics, and the treatment consisted in the exhibition of remedies suitable to the collapse and of the antidotes for oxalic acid—namely, chalk suspended in milk, lime water, and castor oil. The coma and collapse, however, increased and the children died at 12 noon and 2 P.M. respectively, eighteen and twenty hours after they had apparently taken the poison.

At the post-mortem examination, which I performed on the following day, no appearances worthy of record were noticed except a slight amount of congestion in the small intestine of the elder girl. The mucous membrane of the mouth and tongue was in both cases white and shrivelled. I did not detect any perforation. Both stomachs were ligatured and removed into jars which were sent by the wish of the jury after the inquest to Mr. J. W. Knights of Cambridge, public analyst of the Isle of Ely County Council.

I had in the meantime carefully explored the fields in the vicinity and as far as possible traced the path of the children. With the exception of the ordinary cuckoo-pint (Arum maculatum) and the ordinary hemlock (Conium) no poisonous plants were discovered except sorrel, of which several tufts were found.

At the adjourned inquest the evidence of Mr. Knights proved that a small quantity of oxalic acid or binoxalate of potassium was found in the stomach of each. The quantity was not enough to have caused death, but in his opinion sufficient might have been taken and, though afterwards vomited, produced fatal results. He was also of opinion that enough sorrel might have been taken to produce these results. No other poison was detected. These facts and evidences clearly show, I think, that the cases must be ranked as poisoning by sorrel leaves.

Ely, Cambs.

A NEW METHOD OF OPERATING FOR HYDROCELE.

By SURGEON-LIEUTENANT-COLONEL E. LAWRIE, M.B.EDIN.,
RESIDENCY SURGEON, HYDERABAD, DECCAN.

THE operation for the radical cure of hydrocele should be performed in the following manner. The sac is punctured in the usual way and when about a third or one-half of the fluid has been withdrawn two drachms of a saturated solution of bichloride of mercury in glycerine are injected and mixed with that which remains and allowed to rest in the sac for from half a minute to a minute. The whole of the fluid is then drawn off to the last drop. Very little pain is experienced and unless the patient is nervous and takes chloroform he is able to move about immediately after the operation. For the next few days he must as a rule lie about, but need not in any case be confined to bed, and in a week or less he is quite well. Provided the surgeon is careful that his hands and instruments are clean and free from micrococci when the puncture and injection are made they produce a uniform result—i.e., sufficient aseptic inflammation to obliterate the sac and nothing more.

Hyderabad.

FRACTURE OF THE ALVEOLUS OF THE LOWER JAW.

By J. HUTCHISON EDWARD, L.D.S. R.C.S. IREL.

THE following case may not be uninteresting now that the cricket season is in full swing, because of the nature of the accident and the easy, rapid, and complete recovery which followed the treatment. In June last year a man about eighteen years of age, who had been struck in the mouth by a cricket ball, applied to me to have six front teeth (which he said were knocking about in his mouth) extracted from his lower jaw. On examination I found it was not simply a case of loosened teeth, but that the whole of that portion of the front of the lower maxillary bone which contained the alveoli of the six teeth had been broken away and was swinging about in his mouth attached only by means of the membranes of the gum which were intact on the right side, although on the other side they had been torn through. I at once proceeded to secure the teeth with their broken-off alveolar supports *in situ* by means of a gature of silk thread. The fracture extended from the side of the right canine tooth downwards through the alveolar portion of the lower maxilla, passing transversely along the junction of the alveolar portion of the body to the lateral incisors on the left. I then carefully took a model in beeswax of the injured mouth. From this I made a plaster-of-Paris cast, and from this a model in wax again, and from this last a splint of black vulcanite extending from the right to the left molar (inclusive) of the lower maxilla, using black vulcanite in order to avoid the possible irritation which might be set up in the injured tissues by the presence of colouring matter. I also raised the bite a little in order to take off the pressure from the injured portion of the jaw. The patient was required to rinse out his mouth very frequently each day with an antiseptic wash consisting of one part of carbolic acid to twenty parts of distilled water. In about three weeks he recovered and was enabled to dispense with the black vulcanite splint and masticate his food as usual.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ROYAL ALBERT HOSPITAL AND EYE INFIRMARY, DEVONPORT.

A CASE OF DOUBLE OVARIOTOMY, INGUINAL COLOTOMY, AND EXCISION OF THE RECTUM; RECOVERY.

(Under the care of Mr. F. EVERARD ROW.)

AT the present day, when operations are so frequently performed for the removal of ovarian tumours and with almost unvarying success, a practice which, we think, at one time was fairly common—that of removing the other ovary when the operator was doubtful if it was quite normal, in order to prevent the risk of a second operation—should be departed from and the question be left to be decided by time. There does not appear to have been any contra-indication to the removal of the rectum in this case, and the result has more than justified the operation. The growth was, however, extensive, and it will be interesting to know the ultimate result as regards prolongation of life. Some recent statistics[1] give a favourable prognosis after removal of the rectum for cancer; 40 per cent. of those recovering from operation had survived the three years' limit, 8 per cent. of them five years, and four others six, eight, eleven, and thirteen years respectively. The operation is not likely to be abandoned as too dangerous. That stage in its history has long been passed. For the notes of the case we are indebted to Mr. J. J. N. Morris, house surgeon.

A married woman aged forty-four years was admitted to the hospital in June, 1887, suffering from an ovarian tumour. An operation was performed a few days after admission, and a large multilocular cyst springing from the right ovary was with little difficulty removed. She made a most excellent recovery. The highest temperature recorded was 99·8° F., for which there was no apparent cause. She left the hospital within three weeks perfectly well. Five years later in 1892 she was re-admitted with a growth from the left ovary. This also on operation was found to be multilocular and with no adhesions. Recovery was again uninterrupted, and she left the hospital in seventeen days quite recovered. In October of last year, 1895, Mr. Row was sent for privately as she was said to be suffering from "outward piles." On examination it was found that she was in reality suffering from almost complete intestinal obstruction from malignant disease of the rectum and anus. She was a third time admitted to the hospital and two days after admission left inguinal colotomy was performed. Owing to an extremely short mesentery of the sigmoid flexure there was considerable difficulty in getting a sufficient portion of the bowel outside the abdominal wound. The numerous sutures, however, held well and the gut was opened on the third day after the operation from which she experienced considerable immediate and

[1] Czerny: Beiträge für Klinische Chirurgie, vol. x., 1893.

Digitized by Google

permanent relief. Three weeks later, when she was convalescent and accustomed to the altered condition of affairs, Mr. Row excised the anus and rectum, about four inches of the anterior wall, and five inches of the posterior wall. The whole circumference of the rectum was involved and also a portion of the posterior wall of the vagina which was removed. The surgical procedure consisted of incising the perineum in the middle line, cutting around the anus, and then carrying the incision in the middle line as far as the coccyx. Sufficient room was thus secured to grasp the rectum in the left hand, pull it down outside the body, and remove it with scissors, with a portion of the vaginal wall. After the operation a little fæcal matter for a few days came away in the dressings with which the wound was packed — namely, strips of lint soaked in glycerine and iodoform. The sub-peritoneal fat, but not the peritoneum itself, was seen, and there was very trifling hæmorrhage. Again she made a remarkably quick and uninterrupted recovery, the cut end of the posterior vaginal wall becoming adherent just above the skin margin at the site of the anus. She was, in May, eight months after the last ordeal, fat and cheerful, having gained about 10 lb. in weight. She had no prolapse of either the vagina or uterus and the skin in the neighbourhood of the incision was then quite free from signs of recurrence.

Remarks by Mr. ROW.—I do not know that this case calls for any especial comment except to point out the importance of care in aseptic treatment. The patient on three separate occasions ran the risk of death from accidental flaws in the toilet of the peritoneum, in addition to other obvious dangers. As an interesting point I may add that after the first operation, nine years ago, she left the hospital just in time to nurse her husband, who was suffering from an enormous sarcoma of the scapula and surrounding parts which was far too large for removal and who died from hæmorrhage from the axillary artery two or three weeks later.

BRISTOL ROYAL INFIRMARY.

A CASE OF FATAL HÆMORRHAGE FROM A STERCORAL ULCER OF THE COLON COMPLICATING RELIEF OF OBSTRUCTION FROM CANCER.

(Under the care of Dr. GREIG SMITH.)

IT is, of course, a well-known fact that the stercoral ulcers which appear in the bowel above a point of obstruction form an important element in the prognosis of such cases. Varying very much in size and number, they form a source of considerable danger to the patient from their liability to penetrate through the coats of the bowel and produce a fatal peritonitis. In this case it is probable that the operation prevented such a fate by being performed very soon after such an ulcer had given way. As a rule, when the fæcal impaction which has caused the ulcers has been thoroughly relieved, their tendency is towards cure, and fatal hæmorrhage from an ulcer situated in favourable circumstances for repair such as obtained in Dr. Greig Smith's patient after the enterostomy, is, we agree with Mr. Carwardine, almost unknown. For the notes of the case we are indebted to Mr. T. Carwardine, house surgeon.

A man aged fifty years was on April 9th admitted to the Bristol Royal Infirmary complaining of abdominal pain and frequent vomiting. His bowels had not been open for eight days and he had not passed flatus for five days; consequently, there was considerable abdominal distension, and his condition was grave. His illness began about a month previously with a sudden severe griping pain in the abdomen, followed by persistent vomiting, and later by an abatement in the severity of the symptoms. For a while he passed scanty motions of small calibre. An operation was performed the day after admission. On opening the peritoneal cavity a little gas escaped which had a doubtfully fæcal odour. A small indurated mass was found attached to the ascending colon; during manipulation this became detached, and the audible escape of bubbles of gas proved that there was intestinal perforation. Dr. Greig Smith pinched the opening between his fingers and brought it as near to the surface as possible. There was an ulcer with jagged edges at least an inch in diameter, and a small perforation about three inches higher up, while the whole bowel looked unhealthy and congested. The condition of the patient forbidding further operation, the parts were cleansed as thoroughly as possible and enterostomy was performed, the large ulcer being used for the insertion of the large rubber tube. During the next twenty-four hours fæces came away freely and the abdominal distension subsided. On the third day a slough of bowel detached. For a week there was steady progress, although fæces welled up from the greater part of the abdominal incision, which was accordingly opened up freely, exposing matted bowels covered with granulation tissue. This was followed by marked improvement in the wound and in the patient's condition. On the morning of the eleventh day after operation bright blood was discovered oozing from the wound in the neighbourhood of the artificial anus. The patient's bed was soon soaked and he must have lost externally at least a pint of blood. The parts were carefully examined and cleansed, but no bleeding point could be seen. Iodoform gauze was therefore packed in. The patient, however, was blanched and restless, and although the usual measures for the anæmia were adopted he died five hours subsequently.

Necropsy.—On post-mortem examination the cæcum was seen to be the portion of bowel affording an artificial anus. It was congested in parts and had two circular perforations of about half an inch and a quarter of an inch diameter respectively. The surrounding bowels were adherent, but there was no general peritonitis. The colon was largely distended with blood and clot, and a small amount of fæcal matter. The blood reached from the ileo-cæcal valve to the splenic flexure, most being accumulated at the hepatic flexure, where there was a deep circular well-defined ulcer about three-quarters of an inch in diameter, which had all but perforated the peritoneal surface. It was obvious that the bleeding came from this ulcer, and that the blood, after filling the colon, had escaped at, and about, the artificial anus. There was a large annular infiltrating mass of cancer at the junction of the descending colon with the sigmoid flexure, fixed, almost filling the lumen of the gut, and involving a portion of the adjacent small intestine. In this case, therefore, there were two stercoral ulcers in the cæcum and one in the hepatic flexure from which fatal hæmorrhage occurred eleven days after the obstruction was relieved and at a time when the patient was practically out of danger as far as the obstruction was concerned.

Remarks by Mr. CARWARDINE.—The above case appears to be the first of its nature noted, the search for notes of a similar case having been futile. A case is recorded of fatal hæmorrhage from an ulcer at the base of a myoma of the ileum, but no reference has been met with to such a fatality caused by a stercoral ulcer complicating the successful relief of cancerous obstruction.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

Fibroma of the Ovary and Ovarian Ligament removed by Operation.—Anterior Colpotomy.—Impacted Ovarian Dermoid Cyst.—Exhibition of Specimens.

A MEETING of this society was held on June 3rd, Dr. CHAMPNEYS, President, being in the chair.

Mr. DORAN read a paper on cases of Fibroma of the Ovary and Ovarian Ligament removed by Operation, with a series of after-histories of cases reported in the Transactions since 1879. Two cases of fibroma of the ovary in Mr. Doran's operative practice were first recorded: one typical and recently in hand, whilst in the second the tumour was removed in 1889, and though it seemed to present some of the microscopic characters of sarcoma no recurrence had occurred. Eleven cases were tabulated; they included the above, whilst the remainder were reported when recent in the society's Transactions since 1879, Mr. Doran adding after-histories. This was done on account of the question of recurrence, since in four, at least, malignancy was suspected, yet the after-histories proved innocence. Most of the eleven cases bore the naked-eye characters of a fibroma. The suspicious microscopic elements in four cases were apparently connective-tissue cells between bundles of white fibre. Myomata of the ovary were not considered in this communication. In only one case was the disease bilateral. One exceeded ten pounds in weight; but older writers, in days when operation

Digitized by Google

was deferred long after diagnosis, recorded heavier fibromata. In ten out of the eleven cases the tumour was removed by ovariotomy. In none was the operation very difficult, and all recovered. In seven cases no adhesions were found. The pedicle was always anatomically normal and long enough to be secured with ease. In two cases it was twisted without causing the pain and other symptoms so prominent in twisted dermoids. Of the eleven cases free fluid was found in the peritoneum in at least five. Mr. Doran discussed this question at length. The after-histories of the ten operation cases were, without exception, favourable. Eight remained free from recurrence from two to twelve years after the operation. The two which remained recovered rapidly, but were quite recent cases. Though always hard, and heavy, fibroma of the ovary caused less pain than dermoid or any other solid or semi-solid ovarian tumour. A markedly hard and painless tumour moving separately from the uterus in a very young woman was most probably an ovarian fibroma. Pedunculated sub-peritoneal uterine myomata were practically unknown in early womanhood, whilst dermoids, very common in youth, were seldom uniformly hard, and the hardest usually set up the most pain. Sarcoma of the ovary, relatively frequent in girlhood, was nearly always soft and associated with amenorrhœa and cachexia. Ovariotomy was the only treatment for fibroma of the ovary. The abdominal wound bled very freely, as in cases of uterine myoma; it must not be made too short else it may be badly bruised during extraction of the hard tumour. Three authentic cases of fibroma of the ovarian ligament were tabulated. Two were certainly fibromata with cystic cavities; one was said to be sarcoma, but its extreme hardness and slow growth did not favour that theory. This tumour grew to a large size, Mr. Doran's weighing over sixteen pounds. In all three the disease was unilateral and the adjacent tube and ovary were free from the new growth. When large the tumour might become œdematous and soft. Ascites and adhesions did not readily develop. In all three cases the patient was in the prime of sexual life. Menstruation was regular in every case. Diagnosis was hardly possible. The uterus might be enlarged yet free from fibroids. All three tumours were removed. In two cases the tumour alone was taken away, the ovary and tube being saved, but one patient died on the fourth day. There seemed to be no tendency to recurrence, Mr. Doran's case and one related by M. Doléris being both still alive and healthy six and a half years after the operation.—Dr. MACNAUGHTON JONES related a case of fibroma of the ovary occurring in a young girl aged twenty-two. From its painlessness, mobility, and feeling of density it gave the idea of a pedunculated myoma. The tumour was discovered accidentally, as no complaint had been made of any pelvic symptoms. The tumour was removed and found to be of the size of an orange and encapsuled. The paient made at good recovery.—After some remarks by Dr. HANDFIELD-JONES, Dr. HORROCKS pointed out the present unsatisfactory state of knowledge of the histological differences between fibromata, sarcomata, and allied conditions. The difficulty was shown in a case under his care exhibited at this society. The tumour was shown as a case of fibroma of the ovary, and the microscopical appearances of sections seemed to several pathologists to indicate its fibromatous nature, but Mr. Bland Sutton, on looking at the sections, pronounced them to be typical of a sarcoma. Fibromata were collections of connective tissue and sarcomata were essentially connective-tissue tumours, and, judging by fibromata under the skin and elsewhere, it was highly probable that they might remain pure fibromata in their histology and innocent in their action for years, and then become sarcomatous and malignant.—After remarks from Dr. CULLINGWORTH and Dr. SPENCER, the PRESIDENT asked whether Mr. Doran considered survival to prove non-malignancy and, if so, whether he would make this statement of both forms of malignant disease or whether he referred only to sarcoma. If so, what would he say about cases (e.g., of cancer of the uterus) in which no recurrence had taken place?—In reply Mr. DORAN said he had listened with interest to the cases related in the discussion. Not many years ago too much stress used to be laid on the term spindle-celled, so that any normal cellular structures with elongated nuclei were considered identical with the cells which made up the true and very malignant sarcoma of bones and fasciæ. We must mistrust old reports of "small spindle-celled sarcoma of the ovary." When a tumour was diagnosed as an ovarian fibroma it was the duty of the surgeon to remove it. If on microscopic examination it appeared to possess malignant characters and if the patient survived the operation for many years he must not conclude that he had triumphed over malignancy.

Dr. JOHN PHILLIPS read a paper on Anterior Colpotomy. He considered that to Duhrssen belonged the credit of calling attention to this operation. Anyone who had performed either vaginal hysterectomy or fixation could not but be struck with the ease with which the pelvic organs could be examined through the opening in the anterior vaginal cul-de-sac. Full details of the operation, as carried out by Duhrssen, Mackenrodt, and Dr. Phillips were given, with short histories of four cases, in the first of which vaginal fixation only was originally intended. Dr. Phillips considered the advantages of this method to be: (1) no hernia or cicatrix and less liability of the formation of adhesions with the omentum and intestines; (2) greater simplicity of operation and greater rapidity of performance; (3) post-operation sickness was much less and the convalescence shorter; (4) no bleeding of any consequence except occasionally from the vaginal flaps; and (5) no drainage-tube was required. The disadvantages, on the other hand, were: (1) much greater difficulty in making the vagina antiseptic, especially if there was any fœtid uterine discharge; (2) greater risk of wounding the bladder, ureters, and coils of intestine; and (3) if the swelling was adherent in the left and posterior quarter of the pelvis the rectum might be lacerated. A list of cases in which this operation seemed indicated was given. With regard to recommending the operation, Dr. Phillips wished it to be borne in mind, firstly, that the peritoneal cavity was opened with its possibly grave after-results, and, secondly, that the removal of the ovaries and tube whether by vagina or abdomen must always be looked upon as a mutilation, and hence the same care and anxious thought should be exercised as before resorting to abdominal section.—Dr. AMAND ROUTH was glad that Dr. Phillips had brought forward this important subject. There was little to criticise in his remarks, but much to commend, especially in the warning added at the end of the paper. He thought that the two difficulties of the operation were the separation of the bladder and the turning-out of the uterus. As regards the former, he thought that a combined transverse and longitudinal vaginal incision gave the best result. It was not always easy to turn out the uterus, and he had found that the best way was to antevert it per rectum or by a uterine repositor fitted with a rack and screw.—Dr. HORROCKS and Mr. MALCOLM then made remarks, and the PRESIDENT closed the discussion by criticising the indications for the operation. He considered that in cases of small intraligamentous and parovarian cysts where these required much enucleation operation was probably safer from below. He considered, also, that abdominal section as an exploratory measure was very valuable from a diagnostic point of view to be followed up by operation per vaginam. With regard to Mr. Malcolm's remarks on the greater safety of abdominal than vaginal section, it must be remembered that as far as sepsis was concerned the latter was one of the safest operations in gynæcology, as was shown by the results of vaginal hysterectomy.

Mr. THOMAS H. MORSE (Norwich) related a case of Impacted Ovarian Dermoid Cyst which was removed by abdominal section during the ninth month of pregnancy. A multipara aged thirty years, whose last labour had been quite normal two years before, was again pregnant nearly nine months when Mr. C. E. Muriel, under whose care she was, discovered that the pelvis was almost completely blocked with a semi-solid tumour and that the os uteri could only with great difficulty be reached with the index finger passed up close behind the pubes. Abdominal section was performed and the whole tumour, which arose from the right ovary, was lifted out. The pedicle was three inches long and was twisted upon itself one whole turn from left to right. This was ligatured and the ovary cut away. The uterus, which had been outside the abdomen for about five minutes, had been carefully kept wrapped up in warm cloths and was replaced with some difficulty. The wound was united with twenty-one sutures, the whole operation lasting twenty-five minutes. The tumour proved to be a dermoid containing hair and sebaceous matter, with some blood and pus. The walls looked gangrenous. The patient made an easy recovery; a normal labour followed twenty-five days after, forceps being applied to prevent unnecessary strain on the recent cicatrix. The child was living and of full size.

The following specimens were exhibited:—Dr. AMAND

Digitized by Google

ROUTH: A Hydrosalpinx and small Ovarian Cyst removed by Anterior Colpotomy.

Dr. MACNAUGHTON JONES: Microscopic Sections of a Fibroma of the Ovary.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A MEETING of this society was held on June 5th, Dr. A. SYMONS ECCLES, President, being in the chair.

Dr. F. CLEMOW showed a case of Rodent Ulcer in which an area of skin of the upper lip of about the size of a sixpence was involved. Excision, with grafting according to Thiersch's method, had been entirely successful.

Mr. SWINFORD EDWARDS showed drawings taken from a male patient the subject of Acute Phthisis. There were two circumscribed areas involved, one (the smaller) being apparently papillomatous, the other closely resembling eczema. The diagnosis appeared to rest between mucous tubercle and scrofuloderma.—Dr. ABRAHAM suggested that the case presented some analogies with Paget's disease of the nipple.

Mr. SWINFORD EDWARDS also brought forward a case of Chronic Ulceration and Induration of the Lip. The history dated back some twenty years and the original lesion appeared to have been inflammatory. The present condition was not typical and presented some features consistent with epithelioma, syphilis, lupus, or simple ulceration.

Mr. KEETLEY showed a case of Rodent Ulcer of the Cheek and Ala of the Nose treated by Excision and Skin Transplanting, in which, owing to the failure of Thiersch's grafts, an arm-flap had been brought into requisition.

Dr. CHAPMAN showed a girl aged seventeen years, the subject of heart disease, with Œdema of both Legs, there having been an interval of a year between the onset of the swellings on either side. — Dr. CHAPMAN also showed a case of Linear yielding of the Skin from Premature Obesity in a girl aged fifteen years and weighing 12 st. The skin of the shoulders, mammæ, and buttocks was affected.

Dr. ABRAHAM showed a case of Extensive Acne with Comedones of the Chest and Neck and also water-colour drawings of a Congenital Lymphangioma of the Shoulder which had been successfully removed by scraping.

Mr. MCADAM ECCLES showed cases of Osteo-arthritis in father and daughter. In the male patient, aged forty-five years, the hands were affected in the typical manner. His daughter, aged twelve years, had worn ill-fitting boots and presented a painful swelling over the metatarso-phalangeal joint of the great toe.—Mr. ECCLES also showed a woman aged forty-four years whose hand was typical of Osteo-arthritis. She had also swelling of the elbow, probably of the same nature. — Mr. ECCLES exhibited a man aged twenty-eight years, with Cleft of the Soft Palate with Double Hare Lip, who, through debility, had escaped operation during infancy. The clefts on the two sides of the lip were not complete, the intermaxillary bone was not carried forward, but the prolabium was attached to the columna.

Dr. MORGAN DOCKRELL showed a case of Ulerythema in a boy aged eleven years. The end of the nose and both ears were involved.

Dr. WILLIAM HUNTER showed a case of Deformity of the Chest produced by bicycle running in a boy aged sixteen years, well nourished, and of good personal history. His occupation involved a considerable strain, and always with an inclination of the body to the right. He presented a projection of the right edge of the sternum and adjacent costal cartilages with falling-in of the corresponding ribs and another projection of the left costal arch outwards and forwards. On imitating with the right arm the usual position necessary for supporting the bicycle learner the deformity was much exaggerated, while, when placed supine, pressure on the projecting edge of the sternum nearly annulled the deformity. The President pointed out that in addition to the deformity described there was slight gastroptosis, which was probably also due to the excessive strain involved in his occupation.

Dr. HORNE showed a man aged fifty-six years, the subject of General Atheromatous Degeneration of the Arteries. The aneurysm followed a crush of the foot.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Chronic Rheumatic Arthritis in the Rorqual (Balænoptera Rostrata).

A MEETING of this section was held on May 29th, Mr. CONOLLY NORMAN, the President, being in the chair.

Dr. E. H. BENNETT exhibited part of the Skull and First Cervical Vertebra of a Rorqual (Balænoptera Rostrata) which had been dissected by Dr. Dixon on the shore of Achill Island. The articular surfaces showed the eburnation and polish of chronic rheumatic arthritis. Dr. Bennett enumerated a great number of mammals in which he had observed the disease, and discussed the grounds on which he made the diagnosis in this rare instance.—Sir W. STOKES wished to know whether there were any other evidences of chronic rheumatic arthritis present besides the polished condition of the bone, as that was met with in such a variety of circumstances.—Dr. DIXON said there was a considerable amount of intervertebral substance between the bones when he got the specimen, and so the polish was not due to the sand acting on it. No other joint was affected. They were all examined. The vertebræ of the neck were degenerating structures in this species, as was shown by two of them being often fused together, and perhaps as degenerating structures they were more liable to disease.—Dr. BENNETT said that there was no evidence of suppurative arthritis, and the condition was, therefore, due to chronic rheumatism.

SECTION OF ANATOMY AND PHYSIOLOGY.

Genu Valgum Adolescentium.—Ossification of the Third Trochanter.—Effects of Right-handedness on the Sternum.

A MEETING of this section was held on May 22nd, Professor PURSER being in the chair.

The SECRETARY read for Dr. J. SYMINGTON, the President, a communication on Genu Valgum Adolescentium, illustrated by a specimen, showing a condition of extreme malformation in both lower limbs. The patient up to the age of eighteen years exhibited no signs of the deformity. She then went to work in a mill, and soon afterwards the condition shown in the specimens arose. There were some signs of rickets in the upper limbs, but the characteristic enlargements of the anterior end of the ribs were absent. The deformity was extreme, the two thigh bones crossing like the limbs of an X; it was due chiefly to the condition of the diaphyses of both femur and tibia and to a slight extent to the unequal growth of the inner and outer parts of the epiphysis. There was comparatively little change at the ankle. The pelvis was unsymmetrically narrowed, the transverse axis being much reduced.

Dr. A. F. DIXON read a paper on Ossification of the Third Trochanter. Three thigh bones were exhibited showing a special epiphysis for the third trochanter. In each case this epiphysis was small and scale-like and was placed just above the groove present in the region of insertion of the gluteus maximus muscle. An examination of a number of young bones led to the conclusion that, in many cases at all events, the third trochanter in man was ossified from a special centre. The epiphysis was never found to be more than a scale-like piece of bone, even when the third trochanter was very well developed.—Professor BIRMINGHAM said that Dr. Dixon's observations seemed to solve a question which was discussed some time ago by Professor Dwight and Mr. Arbuthnot Lane. The latter held that certain bony projections were produced by the pull of muscles on the bone, but Professor Dwight argued, on the other hand, that this third trochanter was a survival of the third trochanter of the lower animals, and that it was not due to muscular pull. Dr. Dixon's observations proved that Professor Dwight's theory was correct.

Professor BIRMINGHAM made a communication on the Effects of Right-handedness on the Sternum. He had remarked that comparatively few sterna are symmetrical, and he believed that the asymmetry was due to the more frequent use of the right upper limb. On examining a number of sterna the conditions which could be attributed to the more frequent use of one limb were (1) a depression of the clavicular facet on the manubrium, sometimes very distinct, generally fairly marked on the right side in about 66 per cent., on the left side in about 26 per cent., and

Digitized by Google

absent in about 8 per cent.; (2) an apparent compression from above downwards on one side of the manubrium with a reduction in its vertical depth, present on the two sides in the same proportion as the preceding; and (3) a reduction of the interval between the first and second costal cartilages present on the right side in nearly half the specimens, on the left side rarely. In addition the clavicular facets looked more strongly backwards on one side, usually the right, and in several bones the axis of the sternum was curved, the convexity looking to the left. The curve was most marked in the lower portion of the bone, as if this part were pushed to the left by the pressure of the lower right rib.—Professor PURSER was of opinion that right-handedness depended on the brain, the blood-supply to the left brain being more direct, as was shown by the frequency of embolism on that side.—Professor BIRMINGHAM, in reply, said that none of the theories advanced to account for right-handedness were quite satisfactory. He agreed with Professor Purser that the cause lay in the brain.

Reviews and Notices of Books.

The Present Evolution of Man. By G. ARCHDALL REID. London: Chapman and Hall, Limited. 1896. Price 7*s.* 6*d.*

IF the truth of a doctrine is to be measured by the extent of its application then assuredly no doctrine can claim to be more firmly established than that of evolution. Its central idea is capable of being employed for the explanation of phenomena in almost every sphere and phase of organic life, and it is astonishing what a flood of light it has shed upon some of the most obscure places. The special application of the doctrine which has been chosen by Mr. Archdall Reid is perhaps the most interesting of all the studies which have been based upon the hypothesis, and, ably as he has dealt with it, there remain many lines of investigation which are practically untouched as yet. Mr. Archdall Reid has grappled with his task in a masterly manner. He shows that he has himself gained a clear insight into the import and extent of evolution, and although obviously belonging rather to the school of Weissmann than of Spencer, whose dicta he does not hesitate to criticise with much acuteness, he shows that he has devoted much independent thought and considerable learning to the elucidation of the problems before him. The result is a monograph which is crowded with illustrative data and well-reasoned arguments—a work that requires to be read and studied many times before its full import is grasped, and one which deserves in its place as much attention from the thoughtful as any of the numerous writings that have arisen from this most fruitful doctrine. Although the title of the book is "The Present Evolution of Man," it must be said that this particular subject forms but a moiety of it. About one-half of the volume is devoted to the study of organic evolution, which is really introductory to the main thesis. The author deals in turn with Physical and Mental Evolution, showing the analogies between them, and laying especial stress upon evidence of "retrogression." In particular we may mention the sharp line of distinction he lays down between "instinct," that inborn and transmissible faculty of mind, and "reason," which is not transmitted by inheritance, but is acquired by each individual, and, like acquired physical traits, is not capable of being transmitted. This leads naturally to the inference that most, if not all, the mental qualities exhibited by man, and those which characterise more especially different races, are really not inborn, but that it is only the power or capacity for acquiring them that is transmitted. Mr. Reid goes even further in his pitiless logic, and maintains that man's moral nature is equally a matter of education and example. He concludes his most suggestive study of mental evolution by dealing with the subjects of language and religion. Interesting as such speculations are, they are, after all, less practically important to the community than those considerations upon which he enters in the second part of the work. Here he applies the doctrine of evolution to mankind in general, and maintains, with some reason, that it is mainly resolved into a struggle for existence against zymotic disease. He points out that although in process of generations the susceptibility to such disease may lessen, yet at the same time the powers of attack of pathogenic organisms increase. He admits that immunity may be inherited as well as acquired, and obviously inclines to the phagocytic side of this question. Immunity is acquired by the cells undergoing variation in response to appropriate stimulation; and it is suggested that as in rabies, so in syphilis it may be possible to artificially induce this kind of change. On the other hand, leprosy and tuberculosis, to which many individuals seem naturally immune, offer less probability for acquirement of immunity. Those who have once suffered from tuberculosis are as liable as ever to be attacked by the disease. A distinction is therefore made between diseases which act upon phagocytes with powerful toxines and those in which there is rather a direct struggle between microbes and phagocytes. The manner in which this argument is developed is ingenious, although perhaps some of the statements are more dogmatic than is warrantable from the facts. Zymotic diseases may be classified, according to the author, in three groups—namely, (1) in which the pathogenic organisms are entirely parasitic; (2) in which the organisms are not only entirely parasitic, but "are capable of maintaining existence for a limited time as resting spores or otherwise" outside the living body; and (3) in which the microbes can maintain an independent existence outside the living body for an indefinite time—saprophytic, in fact—of which malarial fevers form the chief examples. It is pointed out that these latter are less stable in type than the purely parasitic diseases. Several of these diseases are treated in detail with many suggestive remarks upon the extent to which the evolution of man has increased his resistance to their inroads. We would fain dwell on this part of the work, which is so full of interest for the medical inquirer; but we have already reached our limit and must close this brief notice by calling especial attention to the really remarkable and novel treatment of the question of alcoholism, which forms a fair portion of the section on Mental Evolution. The closing paragraph of the volume tersely sums up the position taken by the author. He says: "In conclusion it is surely clear that if the world is to become more temperate it must be by the elimination, not of drink, but of the excessive drinker. If artificial selection be found impracticable in the future, as, owing to the state of public opinion, it undoubtedly is at present, then the only alternative is natural selection, in which case the world will never be thoroughly sober until it has first been thoroughly drunk." How this seeming paradox is arrived at we must leave to our readers to find in the pages of the book itself—a work which, as we have said above, requires to be read and read again, for it teems with suggestive, if at times daring, ideas.

The Methodical Examination of the Eye. By WM. LANG, F.R.C.S. Eng., Surgeon to the Royal London Ophthalmic Hospital, Moorfields. London: Longmans, Green, and Co. 1895. Pp. 96.

THIS little manual will prove of service to the beginner, and especially to the student who is about to comply with the regulation of the Conjoint Board of the Royal Colleges of Physicians of London and Surgeons of England that he should attend for three months in the eye wards

Digitized by Google

of a hospital. The language is plain and simple, and the directions for the use of instruments easy to be followed, and this might reasonably have been expected from one who has had so large an experience in teaching as Mr. Lang. He has devoted two chapters to the external examination of the eye and its accessories, one to the mode of investigation of the visual powers, and one to the employment of the ophthalmoscope. The first chapters deal with the supra-orbital ridges, the globe of the eye in respect to its prominence, the palpebral fissure in regard to its size and form, and the action of the orbicularis and levator palpebræ muscles. The condition of the lids, lashes, and Meibomian glands is next taken into consideration, together with the appearances characteristic of chemosis, conjunctivitis, and cyclitis. The examination of the iris, pupil, lens, and vitreous is then proceeded with. In passing, it may be remarked that woodcuts of such instruments as "Meyer's syringe" and "Graddy's forceps" might with advantage be introduced into the text, as the student may not always be familiar with them. The account of the determination of the tension of the eye might also have been somewhat extended by giving the terminology in common use for varying degrees of hardness and resiliency of the globe. The mode of testing the sharpness of vision is carefully and fully described, as is also the examination of the refraction of the eye by retinoscopy. A good section is devoted to the examination of the muscles of the eye by means of the Maddox disc and rods and by prisms. Directions are given for ascertaining the field of vision, the light-sense, colour-sense, and the field for colour. Finally, a short chapter contains the mode of practising oblique illumination and of making direct and indirect ophthalmoscopic examinations. Nothing is said in regard to stereoscopic vision. If the student works out a few cases with the aid of this manual he will have neglected no point of importance and will have accustomed himself to make a sound and complete examination of any case that may present itself to him in his subsequent practice.

A Smaller Atlas of Illustrations of Clinical Surgery, consisting of 136 Plates, with Descriptive Letterpress. By JONATHAN HUTCHINSON, LL.D., F.R.S. London: West, Newman, and Co. 1895.

IN this work Mr. Hutchinson has collected in a handy and portable volume a collection of clinical illustrations remarkable alike for their fidelity and their value for teaching purposes. A large number of them depict cutaneous eruptions, and where all are excellent it is difficult to single out instances of exceptional value; but a rare case of eruption, caused by a group of cases of "arsenic psoriasis" and "arsenic cancer," and plates illustrating varicella gangrenosa and Bazin's disease, and different varieties of lupus may be mentioned as deserving of special attention. A remarkable case of chancre of the lip is given to illustrate the difficulty of recognising it in this position. In addition to clinical rarities Mr. Hutchinson has collected some curiosities, one at least of which is probably unique. It is a drawing of a boy's heart into which a cedar pencil was forced six weeks before death. The pencil is lying across the right ventricle and thickly coated with fibrin.

The work is not only of great interest to practitioners but will be invaluable for teaching purposes, particularly if, as Mr. Hutchinson suggests, the plates be separated from the book and remounted with wider margins. Both Mr. Hutchinson and his artists are to be congratulated on the production of this volume, and the chromo-lithographing has been done by the publishers in excellent style. A second volume is projected, and will doubtless meet with as cordial a welcome as this one, which however it will be difficult to surpass in interest and value.

Eyesight and School Life. By SIMEON SNELL, F.R.C.S. Edin. With numerous illustrations. Bristol: John Wright and Co. 1895. Pp. 70.

IT is acknowledged on all hands that the care of the eyes during school life has become an important duty which devolves on parents, teachers, and surgeons. Parents and those engaged in the education of the young should learn that the least expression of discomfort in the eyes, the least peculiarity of the mode in which a book is held during reading, or of the mode in which the head and body are kept during writing, is sufficient to indicate that some defect of vision is present, or, at any rate, that an examination of the eyes should be made to determine whether the defect is due to this or some other cause. In the earlier stages such defects are often remediable, whilst if no notice be taken and years be allowed to elapse conditions are established which may prevent the lad from entering the public services or from competing on equal terms with his peers. As Mr. Snell remarks, although much has been done to bring home to parents and teachers a knowledge of the importance of this subject, no medical man seeing much of eye affections in children can shut his own eyes to the fact that there is still room for a much more widely extended knowledge. The prevalence of myopia in Germany has led the German ophthalmic surgeons to devote an unusual amount of attention to the causes of its occurrence and development; and amongst those who have done most to elucidate these points Professor Cohn of Breslau occupies the most prominent place. Many have since followed his lead, amongst whom Mr. Snell is not undistinguished, and from the labours of all those who have had the opportunity and disposition to follow out investigations on this subject it is now certain that particular attention should be paid to the lighting of schoolrooms, to the construction of desks, the size and clearness of type, and especially of music type, and lastly, to the number of hours of study. Each of these points is ably discussed by Mr. Snell, who gives in addition many photographs of children in the act of writing with good and bad illumination — photographs that show clearly how injuriously imperfect lighting and inattention to position may affect not only the eyes but the spinal column.

JOURNALS AND REVIEWS.

The Journal of Pathology and Bacteriology. Edited by G. SIMS WOODHEAD. Vol. III., No. 4. January, 1896. Lonon: Young J. Pentland. Price 12*s.* net.—This issue contains a large number of articles of importance to the practitioner as well as to the pathologist. After a graceful tribute to the memory of Pasteur by the editor, Dr. Louis Cobbett contributes an important practical article on the Serum Therapeutics of Diphtheria. Dr. Williams and Dr. Cameron of Montreal give an account of several cases in which they found the bacillus pyocyanus in the spleen, liver, &c., of marasmic children. Mr. Westbrook has continued his investigations on the Action of Direct Sunlight on the Cholera Bacillus. He finds that the germicidal action of sunlight is only marked when the layer of culture medium is thin and where there is free access of air. Otherwise growth in the deeper parts goes on more rapidly than destruction at the surface, and the bacilli are as virulent as those grown in the dark. Dr. Ainslie Hollis concludes his important article on Atheroma, and has some interesting suggestions as to the possible connexion between various visceral disorders and atheroma of the aorta. Dr. Ralph Stockman describes the experimental production of anæmia in dogs by withdrawing as far as possible all iron from the food. Dr. Crauford Dunlop contributes a very exhaustive article on Oxaluria. He finds that oxalic acid is

Digitized by Google

a constant constituent in normal urine, and that its precipitation as calcium oxalate is prevented when it is present in small quantities by acid sodium phosphate, and occurs only when the quantity is high. He concludes finally "that oxaluria is no special pathological condition, but is essentially a hyper-acid dyspepsia, and that all its symptoms can be referred to the existence of acid dyspepsia." Dr. Abram corroborates Becker's statement that acetonuria occurs after the administration of anæsthetics, no matter what anæsthetic is employed, the acetonuria persisting for several days. Dr. A. E. Garrod and Dr. Hopkins contribute notes on the occurrence of large quantities of hæmatoporphyrin in the urine of patients taking sulphonal, with a useful account of the methods for separating the pigment. Dr. Watts Eden gives an admirably clear and well illustrated account of the histology of the human placenta. Dr. Hektven of Chicago describes a case of interstitial myocarditis in hereditary syphilis. Dr. Russell Wells and Dr. W. H. Wilson contribute a most important paper on the post-mortem changes in peripheral nerves, showing that decomposition alone will give rise to appearances indistinguishable from those met with in diphtheritic and lead paralyses. Dr. W. Edmunds in a beautifully illustrated paper gives the results of his recent observations and experiments on Graves's disease. Altogether the number is one of the best that has yet appeared. The papers all have a direct bearing on clinical medicine, and those responsible for its production are to be congratulated both on the quality of the articles and the excellence of the illustrations.

The Journal of Physiology. Edited by MICHAEL FOSTER, M.D., F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Vol. XIX., Nos. 5 and 6. Cambridge: C. J. Clay and Sons. May 30th, 1896. Price 8*s*.—The articles contained in this number, which completes the nineteenth volume of the journal, are five in number—viz.: (1) On the Granular Leucocytes, by Mr. G. Lovell Gulland, with two plates; (2) A Contribution to the Study of Lymph Formation with especial reference to the Parts played by Osmosis and Filtration, by Dr. Lazarus-Barlow, with thirteen figures in text; (3) Notes on Rennet and on the Coagulation of Milk, by Dr. Arthur Edmunds; (4) The Regulation of Temperature in Hybernating Animals, by Dr. M. S. Pembrey and Dr. W. Hale White; and (5) On the Changes in Shape and in Position of the Heart during the Cardiac Cycle, by Dr. John Berry Haycraft and Dr. D. R. Paterson. Mr. Gulland considers that sublimate solutions constitute the best means for fixing leucocytes and holds that all varieties of leucocytes are merely stages in the development of a tissue. He divides them into three main groups—the hyaline, the acidophile, and the basophile. His observations and argument demonstrate that the granules of leucocytes are not products of the metabolic activity of the cell embedded in a structureless protoplasm, but are really an altered condition of the microsomes. They are probably concerned with amœboid movement. He does not think that it is possible to determine the diseased organ when they appear in excess in the blood. Dr. Lazarus-Barlow figures and describes (but has omitted to letter) an osmometer, and gives a series of tracings showing the effects of injecting into the circulation equal quantities of equimolecular concentrated solutions of crystalloids upon the lymph-flow. Amongst other results of his experiments he has found that after injecting into the circulation large quantities of weak solutions and small quantities of concentrated solutions of crystalloids and weak solutions of gum the specific gravity of arterial blood falls with great rapidity, but later recovers itself and ends by being higher than before; further, that the specific gravity of voluntary muscle falls after large injections of weak solutions and rises after small injections of concentrated solutions of crystalloids and that the lymph-flow from the thoracic duct is increased both after the injections of weak and of concentrated solutions of crystalloids. He carefully states the arguments for and against the view that osmosis and increased filtration are the effective factors in causing the increased outflow of lymph that is seen after injection of a crystalloid into the blood. Dr. Edmunds shows that the testis, liver, lung, muscle, kidney, and other tissue sometimes contain a very minute trace of rennet or rennet-like ferment sufficient to cause curdling in the presence of excess of calcium. Dr. Pembrey and Dr. Hale White arrive at the conclusion that the power of regulation of temperature observed in hybernating dormice and bats resembles closely that of an immature warm-blooded animal, the evolution of hybernation being due not to the acquisition of a new power but to the retention of one already present in immature mammals and birds. Dr. Berry Haycraft and Dr. Paterson describe carefully the changes in shape which the heart undergoes when the animal is placed in different positions.

The Dublin Journal of Medical Science.—Dr. M. A. Boyd has a thoughtful paper on Defective Metabolism in relation to Gout. At the end of his paper Dr. Boyd very justly remarks, "Clearing the blood and system of uric acid by alkalies or salicylates leaves the principal part of our work undone—namely the correcting of the faulty metabolism. . . . ." We fancy that this fact is often forgotten. Dr. Mouillot writes on the Harrogate Treatment, and there are a number of reviews, and some interesting sanitary and meteorological notes by the editor.

The Birmingham Medical Review.—Mr. Walter Tyrrell writes on the treatment of certain depressed forms of nervous disorders, a form common enough nowadays. He recommends very small doses of nux vomica, say, $\frac{1}{120}$ to $\frac{1}{100}$ of a grain, these quantities to be long-continued. Mr. G. Heaton reports a case of Traumatic Epilepsy with Aphasia and Paralysis. Portions of bone were removed on two separate occasions, and the operation was followed by complete relief.

The April number of the *Intercolonial Medical Journal of Australasia* is full of interesting matter, including Dr. Lendon's presidential address at the Intercolonial Medical Congress recently held at Dunedin and a paper on Tuberculosis of the Skin read at the same Congress by Mr. A. W. Finch Noyes of Melbourne. Dr. Lendon's theme was the Achievements of the General Practitioner, exemplified chiefly by Edward Jenner's life and work. Dr. A. Jeffreys Wood of Melbourne contributes notes on Seven Cases of Scurvy in Artificially-fed Infants successfully treated by Raw Meat Juice and Orange Juice.

The June number of the *American Journal of the Medical Sciences* has a lengthy and instructive paper on the Blood in General Paralysis, contributed by Dr. Joseph A. Capps of the Massachusetts General Hospital. He has directed special attention to the different varieties of colourless blood cells, and concludes that most cases of general paralysis show a slight leucocytosis, averaging about 22 per cent. above the normal. Dr. da Costa of Philadelphia writes on a form of Protracted Simple Continued Fever distinct from typhoid fever.

The Practitioner.—It is a good idea of the editor to make his magazine reflect in its articles the lustre of the hero of medicine for the month. The one chosen for June is James Lind, whose name, as the writer of the article remarks, is almost unknown even to the members of the profession. But England, as a nation, owes more to him than perhaps to anyone else, for, to quote Sir J. Simon, "that scurvy has become an almost forgotten disease is due emphatically to Lind." There are two articles in the body of the magazine upon Scurvy—one by Mr. Johnson Smith,

Digitized by Google

and another on How to Avoid Scurvy in the Arctic Regions by Dr. W. H. Neale, who was medical officer of the *Eira* in 1881. The ship went down, and the crew lived for twelve months upon what they could kill, but had hardly any vegetables. No case of scurvy occurred, and Dr. Neale puts this down to the fact that their hut was well ventilated and that they ate plenty of fresh meat and blood.

The Edinburgh Medical Journal.—Mr. R. W. Parker, whose wide experience at Shadwell gives him every right to speak, has a most interesting paper entitled, "Is Inherited Syphilis Contagious?" The main conclusion to which he comes is that most "inherited syphilis" is not syphilis at all. It would be unfair to the writer to enter more fully into the subject here, but we recommend a perusal of Mr. Parker's paper. Mr. Stitt Thomson writes upon his twenty years' experience of midwifery. He reports 2000 cases without a single maternal death—surely a record. His ideas are somewhat at variance with those commonly taught (all the same he insists upon the strictest cleanliness), but then, as he says, his results are eminently satisfactory.

Science Progress.—Those interested in the bearing of the recent discovery of Argon and Helion on Astronomy will find an excellent account of the subject by Professor Norman Lockyer in the current number (June) of this journal. It is now well known that Professor Ramsay last year examined the gas obtained from uraninite with dilute sulphuric acid with the result "that the twenty-six year old helion had at last been run to earth and D_3 was at last visible in a laboratory." This was the same gas which Dr. Hillebrand obtained in 1888, and which, he thought, was nitrogen. Subsequently Professor Lockyer obtained the same gas by heating the mineral in vacuo. "From March 30th onwards," he says, "my assistants and myself had a very exciting time." One by one the unknown lines observed in the sun in 1868 were found to belong to the gas distilled from uraninite. Further investigation resulted in "catching" in the few-lined stars all the most important lines "at the first casts of the spectroscopic net." Concluding, he says: "The more the work goes on we find that this gas is really the origin of most, but certainly not of all, of the unknown lines which have been teasing astronomical workers for the last quarter of a century." In the same number Dr. Buckmaster contributes a paper on the Hereditary Transmission of Micro-organisms, in which, from the summary of results of observations made upon the subject, it would appear that the placental is far more frequent than the germinative infection and that the share borne by the male in this transmission may be disregarded, as no bacteriological evidence exists to support this view. Further, "the frequency of hereditary transmission of pathogenic germs is exceedingly small compared to other modes of infection" We notice on the title-page that the name of the late Dr. Marshall Ward still appears as a member of the editorial committee.

CHOLERA IN EGYPT.

WE are glad to notice that cholera seems to be steadily decreasing in Alexandria and Cairo. The death-roll reported on the 7th inst. was—Alexandria, 4; Cairo, 18; Gizeh, 18; Tourah, 4; Dessouk, 9; Bassouna, 8; Zagazig, 4; Benisouef, 5; other places, 22.

We have little to add to what we have previously said in regard to this epidemic. The disease was already in the country in connexion with the waning effects of the previous epidemic, but it is alleged that during the late summer and autumn of last year it was freshly introduced into Egypt, Tangier, and other ports of Morocco by pilgrims returning from Mecca. There is no doubt that there were numerous fatal cases of cholera in Lower Egypt between October, 1895, and March of the present year, and that the epidemic has been gradually spreading and developing from that time until its increased manifestations in May last, when the numerous attacks in Alexandria and Cairo and other places gave rise to a cholera scare and the exodus of a number of people from Egypt. According to the last returns the disease appears to be decidedly abating as regards the two cities we have mentioned, but the information from other and outlying places is probably not sufficiently accurate and complete to enable us to define its exact extent or the limits of its spread at the present time. It must be borne in mind that the epidemic may manifest itself in greater force later in the season.

THE ROYAL MEDICAL BENEVOLENT COLLEGE.

THE annual general meeting of the Governors of this College was held at the offices, Soho-square, London, on Friday, May 29th, Dr. Holman being in the chair.

In accordance with the provisions of the Act of Incorporation ten members of the council retired, but nine of them—viz., Mr. A. E. Cumberbatch, Mr. G. C. Croft, Sir Joseph Fayrer, Bart., M.D., K.C.S.I., Mr. J. F. France, Dr. Needham, Mr. B. Pollard, Mr. J. T. Mould, Rev. E. W. Northey, M.A., and Dr. F. Taylor—were re-elected for a further period of three years, with Mr. F. B. Hallowes to fill the vacant place. Sir Arthur T. Watson, Bart., Q.C., and the Right Hon. A. J. Balfour, M.P., were re-elected Vice-Presidents of the College.

The names of the successful candidates for Pensions and Foundation Scholarships were given last week (p. 1607).

In their report the Council state that there has been an increase in the amount received from annual subscriptions, but this is chiefly owing to the special appeal made late in 1894 and to the festival dinner held last year, and they take the opportunity of observing that contributions of less amount than a guinea are most welcome. If every practitioner in the United Kingdom subscribed annually only half a guinea there would be a reliable income of over £13,000 a year; but as the total amount received in 1895 from all classes of subscribers was under £3200 it is evident that the members of the medical profession do not give the College that support which it unquestionably deserves. There are at present fifty pensioners. There are also eighty-nine Pugh pensioners and three Morgan annuitants. There are at present on the books of the institution forty-nine foundation scholars. It is hoped that the new school buildings will be ready early in 1897. It must be gratifying to the Governors that the value of the education given at Epsom College is so widely appreciated, and the Council would be glad if all supporters of the College would make a point of bringing the advantages of the school before their non-medical friends in order that there may be a material increase in the number of boys other than the sons of medical men. The enlargement of the chapel is progressing favourably. The health of the school on the whole has been excellent. In the recent Lent term there was an outbreak of measles and also several cases of mumps; otherwise there has been little illness of a serious character.

In moving the adoption of the report, which was subsequently agreed to, the chairman said the tone of the report was satisfactory, marking all-round progress. The balance sheet showed a small loss, but this was explained by the fact that they had virtually no capital account and everything had to come out of revenue. The school practically supported itself and would soon be worked at a profit. What they wanted was the £6000 a year which was given away. More lay boys were wanted. The repute of the school was growing. He wished particularly to point out that the sanitary condition of the school was unquestionably good and that the sickness and the epidemic of scarlet fever were imported from outside the school. Every possible care was now taken that no disease is introduced into the institution.

The formal business of the meeting was brought to a close with a well merited vote of thanks to Dr. Holman for the great services which he renders to the institution and for his able conduct in the chair that day.

THE LANCET.

LONDON: SATURDAY, JUNE 13, 1896.

THE present week has in a very marked manner directed the attention of London to the needs of the London hospitals. The case of Guy's Hospital has, in particular, been thrown into prominence by the function at the Imperial Institute, over which the Prince of WALES presided on Wednesday evening last. Elsewhere in this impression an account appears of the celebration, and we cordially commend to the attention of our readers the very telling appeal made on behalf of that old and now impoverished institution by the Prince and Lord ROBERTS. This appeal was addressed especially to the wealthier classes, and we doubt not that the rich and fashionable assembly which gathered round the Heir-Apparent on Wednesday last will make a suitable response. But it is not possible to state the case of one of the general hospitals of London without stating the case of all. They are all doing the same work in different localities; they are all dependent upon voluntary charity, and they all attain to a standard of efficiency which entitles them to a full measure of public confidence. These are considerations which commend them to the sympathy and support of all classes equally, and the clergy who will to-morrow address the thousands of London in support of the hospitals generally will have to this extent the same story to tell and the same appeal to press home which were on Wednesday last laid before the Prince's guests. Our Special Supplement, which we published last week in support of to-morrow's collection, affords the best proof of this, for it will be found that substantially the argument of that appeal follows the same course as that which at the Imperial Institute elicited as a response a gift of £167,000. But there is an aspect of the work which was hardly touched upon on Wednesday last, and which certainly should not be lost sight of, for it illustrates in the most striking manner not only the magnitude and importance of hospital work but also its resourcefulness. We refer to the synoptical statement of an ordinary hospital staff. It is there shown how the work of every department is carried on by a most elaborately organised staff, and by its means it becomes possible even for those to whom the facts are new to understand the precision with which every want of the patient is provided and the way in which the easy and regular working of all the machinery devised for his relief is secured and maintained.

It has been pointed out that through the misplacing of a decimal point we were led to understate quite considerably the amount of the average contribution of individual Londoners to the Hospital Sunday collection, and that this average contribution should have been estimated at nine farthings instead of one. The correction is due both to our readers and ourselves, and the slip, easily made in the pressure of preparing matter for the printer, would nevertheless have given us some concern if its correction had entailed any modification of our argument. It is, however, a mere inaccuracy, for even when corrected it leaves the substance of our appeal unaffected. The average Londoner spends about £2 10*s*. a year in beer according to the statisticians, something between 8*s*. and 10*s*. upon tea, and upwards of 10*s*. upon sugar. These figures probably represent with rough accuracy the scale of annual expenditure per head of the population at the present time, and present an under-estimate rather than an over-statement. It can, then, be no answer to an appeal founded upon the starved condition of the London hospitals that the average Londoner's charity amounts to nine farthings in the year. We make the correction, as we have said, because it is due both to our readers and ourselves; but we draw attention to it because it occurs to us that we have hardly used the fact in our original statement for all that it is worth.

WE have to congratulate Guy's Hospital upon the success that has attended their appeal to the public for re-endowment. It is true that to place this ancient charity upon its former splendid pecuniary basis an additional sum well-nigh twice as large as that announced on Wednesday night as already collected is required, but this must not blind us to the fact that £167,000 is a noble response from the public to the hospital's declaration of want. Where all have worked so well towards a good end it is almost invidious to point to one influence more than another as having brought about the substantial result. We must be clearly understood to be thoroughly recognising the labour, enterprise, and energy of the staff and past and present members of Guy's Hospital when we say that the greater part of this money has flowed into the re-endowment fund in response to the personal nature of the appeal made by His Royal Highness the Prince of WALES, the new President of the hospital. The Prince of WALES is the ideal leader for such a movement quite apart from his position as Heir to the Throne. He is experienced in the workings of organised charity and he is an immensely busy man, so that the mere fact that he was able to give his time to assisting the movement stamped that movement in the eyes of other busy men as one which they would do well to support. Again, his popularity is unbounded, so that loyalty to the throne, respect for the business man and real affection to the person of the Prince have all operated and coöperated in determining subscriptions towards the object in which he had declared himself to be deeply concerned for success. Second only to the personality of the Prince of WALES as the leader of a movement, political or social, comes that of Mr. GLADSTONE, and the veteran statesman has also lent his invaluable assistance to Guy's Hospital. The sum which has been received in response to his circular letter reached no less than £16,000, that is, one-tenth of the total amount subscribed; while a legacy of £35,000 from the late Mr. INCLEDEN was probably due to the same influence. Happy, indeed, have Guy's been in their champions.

Happy, also, have these champions been in the cause for

Digitized by Google

which their advocacy has been given. The singular justice of the claims of Guy's Hospital upon the public for financial help is recognisable at once, and can be stated in a sentence: Their deplorable financial position has been reached through no fault of their own. Always well managed, always in the first rank as a home of medicine and surgery, and a nursery of young men of science, the hospital has fallen upon evil days entirely on account of agricultural depression. The whole of the funds by which the charity is maintained have been by the direction of the donors invested in what seemed at that time to be the most substantial security that could be selected—land. The administrators of the charity have had no choice; into land the money was forced to go. For a time all went well, and at some seasons not so very far distant extremely well, but of late the value of land in many parts of England has fallen from a half to even a tenth of what it was twenty years ago, and with this fall the income of the hospital has declined until it has dwindled to £20,000 per annum, barely a moiety of what it had previously been. Here is no story of bad management or reckless investment. The money has simply been placed where by law it had to go, and, owing to unforeseen circumstances, constituting really a political revolution, it has shrunk to one-half its size. But one charge could possibly be brought against the governors if we were to look round for a reason to attribute blame to them, and of it they are able to clear themselves so nobly that their refutation constitutes in our eyes their most valid claim upon the public. It might be urged—Why did not the authorities of Guy's Hospital save in their prosperous days lest evil ones should be in store for them? They did not because, having enough for themselves, they thought it better for the cause of humanity that other institutions should benefit rather than that they should accumulate a surplus. In the palmy days of farming their income was so large that with splendid liberality they declined to receive donations of which less fortunate charities stood in more urgent need. This generosity has cost them dearly, for owing to "the well-known wealth of Guy's Hospital" legacies have not reached the hospital, donations have been few, and the endowment of beds a thing almost unknown.

Let us hope, then, that the remaining two-thirds of the half-million which Guy's Hospital requires will be forthcoming. The present sum would make a splendid stop-gap for immediate needs and would even allow the hospital to maintain its former complete efficiency for ten years or so; but these are not the purposes for which the re-endowment fund should be used. What is required is the capitalisation of sufficient money to maintain the hospital at its full working power, not a sum to tide them over temporary difficulties.

THE General Medical Council rose on Tuesday, having sat seven days. The subjects on which it had to deliberate included many which involved points of great importance and some delicacy. We have already commented on one of these in regard to which the deliberative quality of the Council has yet to be tested. Mr. TEALE'S statement of the case against the multiplication of examinations was necessarily somewhat academic in its character and was the better for being so. But this is the mere introduction of the subject. It is the basis of an attack on our system of examination, which system threatens to injure the education it is supposed to test. It rests with the Examination Committee to refute or to accept Mr. TEALE'S charges, and in the latter case to give a practical form to objections extensively shared by those who have paid any attention to the matter.

Another subject of great importance—having regard to the function and reputation of the Council—is its action in the matter of the Apothecaries' Hall of Ireland. Whatever the Council might have done was sure to be criticised from many different points of view, and what it has done will also be well criticised, although done on the motion of one of its ablest and most experienced members, whom Dr. TUKE called "the old Parliamentary hand." Its various critics will do well to remember that the Council cannot look at matters from any particular point of view. It is a complex body, it is in a certain sense a judicial body, and it is bound by its very nature to take a number of things into consideration which do not trouble critics with short and easy methods for the extinction of the least fit. The Privy Council, it will be remembered, declined to go fully into the case at its late hearing and showed a decided wish that the General Medical Council should relieve them of the duty of doing so. The reluctance of the Privy Council was most sensible and it was most respectful to the General Medical Council. Sir DYCE DUCKWORTH spoke as if the Privy Council were asking the General Medical Council "to do its dirty work." This is an entire misapprehension. There is no reason to think that the Privy Council will be one whit less ready than the General Medical Council to extinguish the Apothecaries' Hall if it fails to justify its claim to further existence. But the highest court of appeal naturally demands that before the extinction of the Hall it should have every chance to show its *raison d'être*. In a poor country like Ireland it seems scarcely fair to leave the whole work of non-university qualification to be done by a Conjoint Board which works more expensively than any similar board in the United Kingdom and which drives away to a neighbouring division of the kingdom a large proportion of its own students. Moreover, it was impossible for the Privy Council to overlook two considerations—first, that whatever the faults of the Apothecaries' Hall it was acting in association with another and a powerful corporation; and, secondly, that for the discharge of the existing obligations to candidates who have already been examined by it this Board must continue in existence for five or six years longer. Sir WILLIAM TURNER, with his practical mind, seized on this circumstance and based on it a most valuable suggestion—viz., that the two corporations should be asked by the Council to reconsider the whole question and to reconstruct their conjoint scheme in a way that should make each of them responsible for the whole examinations and should be satisfactory to the General Medical Council. The voting of the Council on this motion and its competitors was unfortunately very close, and this seems to show that some of the members had a difficulty in making up their minds. But the more the motion is considered the more reasonable does it appear,

Digitized by Google

and the greater it seems must be the responsibility of the Royal College of Surgeons in Ireland if it refuses to entertain the suggestion of the General Medical Council. It cannot be the interest of the medical corporations of Ireland to call into existence a new kind of State examination that might compete with them, or to necessitate by a dog-in-the-manger attitude the interference of the General Medical Council, still less of the Privy Council.

This is eminently a case for Home Rule—for showing that the medical corporations of Ireland can meet all the wants of the people of Ireland, and they will have only themselves to blame if they do not succeed. There was great force in the complaint of Sir PHILIP SMYLY that in the old arrangement the Royal College of Surgeons in Ireland had no control over the appointment of medical examiners. Unless this is altered the College will be well advised in refusing to entertain the suggestion of the General Medical Council. And, indeed, the Council itself would probably not sanction a scheme which does not make both parties jointly and separately responsible. But if such an arrangement can be devised it will be a wise and magnanimous procedure on the part of the Royal College of Surgeons in Ireland to give entertainment to the proposal of the General Medical Council. At the same time, the Council must be prepared for the failure of Sir WILLIAM TURNER'S suggestion, especially after the very narrow and halting majority by which it was carried. And it must be admitted that the outlook of the Apothecaries' Hall of Ireland is very uncertain. It is difficult for either the Privy Council or the General Medical Council to preserve a body whose diplomas are in such little demand. The only excuse for attempting to do so is that this small demand may be partly the misfortune of the body as well as its fault, and that in the economy of Ireland there is room for a Board whose conditions and cost are on a somewhat lower scale than those of the other Conjoint Board of that country.

Annotations.

"Ne quid nimis."

THE ARMY MEDICAL OFFICE AND SERVICE.

WE understand that a very legitimate subject of grievance among the Army Medical Staff has been removed. The practice has always hitherto been in the headquarter office of the medical service to have a post which should rightly be occupied by a medical officer filled by a civilian clerk. Everything connected with the roster, the movements of medical officers and the representations of their claims and wishes to their chief, should be most properly and fittingly committed, anyone would think, to an officer of their own service. That seems to us so correct in principle as to commend itself and to require no words of comment. We are glad, therefore, to recognise that the new Director-General has made this one of the initial reforms of his office. Medical officers very naturally desire to approach their own head through one of themselves, who may be reasonably expected to understand and appreciate their objects and requirements and to be more in sympathy with them than any civilian could be. It strikes us that what is wanted in the present unsettled state of the department is a strong man at the helm with the courage of his opinions. Things appear to have been somehow drifting of late in the wrong direction. With the advent of a new Director-General an opportunity occurs for considering not only what is right for the medical service itself, but what is best for the public service as a whole. Some clear and settled policy should be arrived at after careful and impartial consideration, with a determination to stick to it. It would not surprise us if some radical changes were soon introduced into the medical service, seeing that Lord Lansdowne is the present War Minister, and that we have a new Commander-in-Chief in the person of Lord Wolseley as well as a newly-appointed Director-General.

MEDICAL CERTIFICATES AND BOARD SCHOOLS.

IN THE LANCET of May 23rd we commented upon the action of the Macclesfield School Board concerning its wish to appoint a medical officer. We also expressed a doubt whether any medical man would apply for the post, and we now learn that only one did so, and he of course was appointed. We congratulate the board on having obtained the services of so good a man as Dr. Swail, but we condole with him on the unpleasant task he will have of supervising the certificates of his brother practitioners, and that too at the bidding or upon the judgment of the clerk, a gentleman who presumably has no medical training whatever. To certify whether a school child has measles or chorea is indeed a solemn and responsible task, and the board, we see, marks its sense of this responsibility by paying a whole shilling. Meanwhile we suppose the Macclesfield practitioners will be allowed to sign certificates dealing with such an unimportant matter as death, for instance, without having a clerk to sit in judgment and without receiving even a shilling.

THE POWER OF MAGISTRATES TO HEAR CERTAIN CASES IN CAMERÂ.

SOME months ago a long correspondence was published in the *Times* as to whether magistrates possessed power to hear cases with closed doors, the various correspondents dealing with the question in its more strictly legal aspect. Then followed the notice of the proposed Bill to regulate the publication of cases in which the details were of a nature which rendered their suppression desirable. In an annotation which appeared in THE LANCET it was suggested that as magistrates did possess the power of hearing cases in private—as shown by the action of two provincial stipendiary magistrates, in cases which were instanced — the practice might with great advantage be adopted in all those unhappily numerous cases which come almost daily before magistrates in towns and cities and much too frequently even in county police courts. In these cases the details are not only wholly unfit for publication in the daily press, but also to be heard by any but those who are officially engaged in the case and are obliged to hear them. Those members of the profession whose painful duty it has been to give evidence on these occasions know how extremely unpleasant it is to do so before the very persons who ought to be excluded, a number of coarse-minded, idle men, whose reason for remaining in court is to gratify a very idle and gross curiosity. It is with great satisfaction that we have now to record the action of the magistrates in the most recently reported case of the kind. On the 21st ult. a medical man practising in Liverpool was charged before the magistrates at the County Police-court, Birkdale, with indecently assaulting a girl under the age of sixteen. Mr. Collingwood Hope, who appeared for the prosecution, applied to the bench to hear the case in private. He felt fully the responsibility of such application, but having regard to the fact of the serious charge made by this young girl against a medical man, he asked, in

Digitized by Google

the interests of justice, that the bench should exercise the prerogative they undoubtedly possessed and hear the case privately. He felt sure that the bench would consent when he stated that if, after the magistrates had heard all the evidence, they felt that it was not a case for conviction, grave, serious, and even irreparable injury would have been done to this girl. In reply to Dr. Barron, who was one of the magistrates hearing the case, and who asked if the term "irreparable" applied to the fact of the case being heard in public, Mr. Hope observed that all the facts which could not be substantiated would be announced broadcast, no good object could be served by publishing the details, and hearing the case in private would not interfere with justice. Mr. Steel, who appeared for the defendant, agreeing to this course, the case was put back till all the other business was disposed of. The court was cleared of all save those concerned in the case, and after a four hours' inquiry the bench dismissed the case. We trust that in the interests of morals and for the honour of human nature that this course will be adopted in all cases in which it is obviously desirable.

THE VACANT PHYSICIANSHIP OF THE ROYAL INFIRMARY AT NEWCASTLE-ON-TYNE.

THE election of a successor to Dr. Philipson will take place on Thursday, June 18th. Formerly the election was a formidable affair for candidates who had to canvass the governors. Now it rests with a selection committee, which is composed of the consulting physicians and surgeons, the physicians and surgeons of the Infirmary, the members of the house committee, and a certain number of governors, in all numbering sixty. The election is by ballot, canvassing on the part of a candidate being a disqualification. It would be hard on a candidate to visit with a similar punishment the indiscretion of puffing newspaper friends, writing even before the occurrence of the vacancy. Such sin is apt to bring its own punishment. We may trust such a committee as we have described to realise the importance of their duty and to discharge it with impartiality. The candidates include George R. Murray, M.D. Cantab., &c., Vickerman H. Rutherford, M.B. Cantab., and Thomas Beattie, M.D. B.S. Durh. &c. The committee will have no difficulty in selecting a physician whose appointment will be recognised far beyond the district of Newcastle as the reward of merit. On the same day a special Court of Governors is summoned to appoint Dr. Philipson honorary consulting physician—a graceful and proper way of continuing his long and beneficial connexion with the Royal Infirmary. He has acted for some years as vice-chairman of the house committee. It is gratifying to know that in this double capacity he will still be able to render important aid to the chief medical institution in the northern counties of England.

DOLCE FAR NIENTE.

THOUGH it be true in a way that medicine has no politics, and though medical men would treat with equal readiness small-pox in a Radical or in a Tory, yet we think it our duty as medical journalists to offer a word of warning to the Government. In a hymn formerly, if not at present perhaps owing to the revival of taste, popular among what Mr. Gladstone in a recent utterance called "independent religious bodies" there occur the lines—

> "Doing is a deadly thing,
> Doing ends in death."

This is, indeed, a form of sound words. The late Government did not shine at the polls, not, indeed, because they had done too much, but for merely trying. The present Government is on its way to disaster by the same methods. If only a Government would arise and say, "No great measures will be undertaken, but we will devote ourselves to making existence more comfortable," people would arise and bless it. There is an opportunity now for our rulers to earn everlasting gratitude by bringing in and passing a Streets Bill. There is Mr. Jacoby's admirable Street Noises Bill, a birth-strangled babe we fear, for this session, which would make a foundation. Among other clauses of such a Bill the following are suggested. A clause to prevent gas, water, electric light, telephone, drainage, and pneumatic companies from digging up the roadway directly it has been laid down; a clause to prevent carts full of decomposing bones, fat, and other filth being driven slowly along the street at all hours of the day; and a clause to prevent beer-barrels, sacks of coal, and perambulators loaded with market produce being rolled along or across the pavement except between certain hours. With regard to beer and coal we believe there is a Police Act dealing with their delivery, but it is quite obsolete or never acted upon. Attention to all these matters would enormously benefit the health of the dweller in towns, and we are sure a Bill to bring about this consummation would easily pass. Education rating and benefices are but apples of discord. A Bill such as we have indicated would, we believe, unite every party in the House.

BENEFIT NURSING ASSOCIATIONS.

SOME twelve years ago Miss Broadwood founded at Ockley (Surrey) a local nursing association for the benefit of the poor who could not afford to pay for the services of a trained nurse. She accepted as her model a plan which had been successfully tried at Holt (Norfolk), where—hospital-trained nurses having proved to be unsuitable for cottage cases—a staff had been formed from a humbler class of women accustomed to nurse amongst cottagers. A number of parishes were affiliated together, one or more cottage nurses engaged, and a secretary was appointed. Each parish guaranteed a certain sum annually towards paying the nurses' and other expenses. A sliding scale of fees and subscriptions was fixed, sufficiently low to enable people of every class to engage the services of a nurse, the inducement to the poor to subscribe being the right to have a nurse at half-fees. The nurses employed lodged in different parts of the district, and when nursing boarded with the family of the patient, save in exceptional circumstances. Occasional nursing was undertaken, but obviously over such an extended and thinly populated area very little of this could be done. In this respect the system differs from that in which "district" nurses are employed. The Ockley experiment proved so successful that Miss Broadwood made public the results, and since then about 100 other districts have formed local associations working on the same lines, and the system is now known as the "Holt-Ockley." The incessant inquiries for particulars and the appeals for aid in obtaining cottage nurses and in establishing fresh centres led Miss Broadwood to urge that all the centres should be affiliated and have an office in London. The Affiliated Benefit Nursing Association was thus formed and has its office at 12, Buckingham Palace-road, W. Having completed the second year of its existence, by the permission of the Duke of Sutherland a meeting was held at Stafford House on the 4th inst. Miss Broadwood reported that eighteen fresh centres had been formed during the year, that fifty-seven women had been sent to Plaistow (Sister Katherine's nursing home) and elsewhere for training, and that most of these had been engaged by the various branches of the association. The Duchess of Sutherland gave an account of the establishment of several centres in Sutherlandshire, and bore testimony to the immense service the nurses had been to the labouring classes in that county. Mr. J. H. Cheatle spoke upon the conditions under which cottage nurses should attend confinements by arrangement with medical men; Mr. Horace Manders urged the desirability of utilising workhouse

Digitized by Google

infirmaries for training this class of nurse, and Dr. Thresh described his experience in connexion with practical training at the Essex County Cottage Nurses' Home at Leytonstone. The growth of this association and the great interest which is being evinced upon the subject of nursing for the poorer classes seem to indicate that cottage nurses—women taken from cottage homes and who have had a short course of training—are of real service, especially in rural districts, and that in future the cottage nurse will come to be recognised as having her own particular sphere of usefulness.

THE FUNERAL OF SIR GEORGE JOHNSON.

SIR GEORGE JOHNSON was buried on Monday last, June 8th. The first portion of the burial service was read at St. James's Church, Piccadilly. Bishop Barry, the rector, and the Rev. Dr. Wace, Principal of King's College, London, officiated, the former delivering a short address on Sir George Johnson's life and work. Amongst those present were Sir W. Priestley, M.P., Sir William MacCormac, Sir Richard Quain, Sir Joseph Lister, General Sir R. Wilbraham, Sir John Williams, Sir J. Banks, Sir W. Brooks, Sir Joseph Fayrer, Sir Dyce Duckworth, Dr. Wilks, Mr. Christopher Heath, Dr. Dickinson, Dr. Playfair, Dr. Liveing, and Mr. S. B. Bancroft. Sir Alfred Garrod and Dr. Tirard, as medical attendants during the last illness, followed with the relatives, who alone accompanied the body to Addington, near Croydon, where the remains of Sir George Johnson's wife repose. The service at St. James's Church included the hymns, "Lead, kindly light," and "On the Resurrection morning." A most appropriate text appeared in the copies of the burial service summarising Sir George Johnson's career: "I have fought a good fight, I have finished my course, I have kept the faith."

ASTASIA-ABASIA.

A CASE of this disease is recorded by Dr. A. A. Eshner in the *Journal of the American Medical Association* of May 16th of this year. Astasia-abasia may be accepted as a convenient designation for a clinical condition characterised by inability to stand or to walk, but not dependent upon actual paralysis. As a rule sensibility, muscular power, and coördination are preserved, though the disorder may be associated with hysteria or organic disease of the spinal cord. The case described by Dr. Eshner was that of a woman aged forty-six. There was a decided neurotic taint in the family. From 1871 to 1892 she smoked tobacco constantly and had suffered from nicotinism. In 1878 the "speech had been partially paralysed," the disturbance having set in abruptly and being unattended with any concomitant disease. For ten minutes the woman was totally unable to speak, and only with difficulty for two or three hours more. In 1893 the patient observed that contact of the hands with cold water and exposure to draughts of air would cause her to fall. Previously to this there had been numbness in the toes and difficulty in walking. When she came under observation she complained irregularly of icy coldness of the feet, extending half way up the legs, and at times of a sense of burning in the same parts. The bowels were obstinately constipated. She could not distinguish between the desire to defecate and that to urinate. The digestion was poor, but the appetite was fairly good. The tongue was slightly coated and dry. Sleep was good and refreshing. Headache was only an occasional symptom; when present it was supra-orbital and vertical. Occasionally there was vertigo. On inclining the body forward and flexing the trunk after meals vomiting resulted. The patient was annoyed by a sense of the presence of hair in the throat. She had never had a convulsion or lost consciousness. The patient appeared quite unable to walk unsupported. When asked to make the attempt she threw her arms about rather incoördinately and swayed upon her feet. She was unable to stand at all with her feet together. She maintained that the right leg felt heavy. She could walk up and downstairs with the aid of the bannister. She volunteered the information that she did not fall when her feet were warm, and that she did not topple over in her own room. The knee-jerks were greatly exaggerated and ankle-clonus was represented by a few contractions of the foot upon flexion. So far as could be determined there was no other derangement of motility, and the muscles used in walking and standing possessed the power of performing other acts. Sensibility was generally preserved. The right pupil was a little smaller than the left; both were regular and reacted to light. The patient was rather pallid and of poor nutrition. She pointed out a small spot as large as a pin's head upon the left ear, which for two or three months had from time to time been the seat of intense burning. The patient was extremely detailed in her account of herself, and in this she was supported by her husband. Dr. Eshner regards the case as clearly a hysterical one, all of the symptoms and attendant circumstances, including the family history, supporting such an opinion, but he thinks it must none the less be viewed with a good deal of seriousness and the prognosis be guarded. This case, he says, and allied ones cannot be viewed as manifestations of merely functional disturbance. It is far more probable that there have taken place nutritional changes which become more and more pronounced with the progress of the case and which in time may lead to structural changes.

PAROCHIAL BLACKMAIL.

OFFICIAL custom does not often err by spoiling justice with generosity. Its fault far more frequently is on the opposite side. In its estimate of medical service this less agreeable characteristic is apt to be only too apparent. With curious inconsistency, moreover, the medical practitioner is in many cases expected to set an example of liberality. It is so when he attends as witness at a coroner's inquest. On such occasions an officer of the court invariably absorbs the odd shillings of his fee. On a recent occasion when the medical witness was ordered to make a post-mortem examination he was somewhat surprised to find that a mortuary-keeper who acted as his assistant was likewise entitled under a vestry order to claim the, for him, not insignificant sum of 5*s*. for his services. It is worthy of notice that no mention was made of this honorarium before the work had been done. These modest reductions combined amounted to a sixth of the whole medical fee, a fairly substantial discount. Custom, under such circumstances, clearly requires some alteration. The practitioner either is or is not entitled to a certain legal remuneration. If he is, why should the amount due to him be reduced by a wholly needless exercise of charity towards the regularly paid coroner's officer? If he should also require the aid of the mortuary keeper in making a post-mortem examination, or in any other matter connected with the inquest, he may surely be allowed such necessary assistance without payment. It would be advantageous to have the duties of mortuary officials clearly defined. We are not aware that they are too onerous. At all events it would seem that time can be found for work in the post-mortem room if there is a good fee in prospect. There are other conditions affecting the work of medical men in public mortuaries which will not bear too close examination. Better warming arrangements are in winter absolutely essential to good work. Warm water, clean towels, soap, nail-brushes, and disinfectants (such as can be used to the hands of the operator) are as often absent as not. Yet no one acquainted with the responsibilities of medical men who are daily engaged in surgical and obstetric practice will deny that they are absolutely indispensable,

Digitized by Google

not only to the safety of the practitioner but of the public. Why, then, should the onus of precaution rest only on the former? Any additional expenses incurred by providing such needful additions as we have indicated for the post-mortem room would not be heavy, and they should certainly fall upon vestries or municipal councils and not on the comparatively disinterested medical expert.

THE ROYAL SOCIETY CONVERSAZIONE.

"LADIES' NIGHT" at the Royal Society was held on Wednesday last, when, as is usual, many of the exhibits shown at the previous annual conversazione (in May) were repeated. On the whole, however, the exhibits were of a still less striking character from the point of view of display. The "New Photography" appeared to draw the keenest interest, and an excellent demonstration was given by Professor Silvanus Thompson. He showed the production by "x" rays of electric dust shadows and the exhibit included a number of new forms of "x" ray tubes, and notably one for insertion in the mouth. Professor Thompson employed "scheelite" or native tungstate of calcium on the fluorescent screen. Mr. Herbert Jackson repeated his demonstration of the use of phosphorescent materials in rendering "x" rays visible, and Mr. J. S. H. Teall showed an excellent series of photographs of the electric discharge at various stages during the exhaustion of a Crookes's bulb. Bordering on the same subject was the brilliant exhibit of Messrs. Siemens Brothers and Co., which illustrated the history and development of the electric discharge in vacuo. Thus there was to be seen a facsimile of the first vacuum tube ever constructed which was by Dr. William Watson in 1751. In regard, however, to the application of the "x" rays to medical diagnosis the series of photographs shown by Dr. Macintyre are undoubtedly a great advance on any previous productions. He exhibited photographs showing besides the hard tissues the soft tissues as exemplified in the series including the neck, tongue, larynx, heart (normal and abnormal), diaphragm, muscles, &c. Coming to the exhibits that were not previously shown—and they represented not more than one-third of the entire demonstration—the photographs of the hæmatozoa of fly disease of South Africa attracted a good deal of attention. As is well known, for the last half-century the tsetse fly has been notorious as a terrible scourge to live stock and a most formidable impediment to colonisation in Equatorial and South Africa. It has now been discovered by Surgeon-Major Bruce that the fly is itself innocuous, and is only fatal to animals when it is the carrier of a flagellated infusorian (hæmatozoon), which it introduces into the blood. Close by were models of the curious flowers of *Aristolochia gigas* from Brazil and of *Stapelia gigantea* from Natal, which have the extraordinary property of exhaling a sickening fæcal smell which attracts carrion flies and dung beetles in abundance. They are described as being provided with indoloid scents and resembling animal corpses in their colouring, having usually livid spots, violet streaks, and red-brown veins on a greenish or fawn-coloured background. In the exhibit of the Applied Mathematics Department of University College we noticed diagrams illustrating the relative variation of different organs in men and women of divers races, and diagrams also showing that 25 per cent. of the married population produce 50 per cent. of the next generation. The research apparatus, which is intended for the Davy-Faraday Research Laboratory of the Royal Institution, made an excellent display, and was presided over by Mr. Robert Mond, son of the generous founder of the laboratory. Standing in one corner of the library was Professor Dewar's apparatus for the production of liquid air and oxygen, which he has reduced to the limits of comparative portability. The tuneful experiments by Mr. Joseph Goold were exceedingly interesting, and consisted in a pictorial demonstration of the axes of sound vibrations by means of powdered chalk dusted upon the tuning bar. Professor Herkomer showed his "Herkomer gravures," their method of production being also the subject of an interesting demonstration in the meeting room. A lantern exhibition by Professor A. C. Haddon was given also at an earlier hour in the same room, illustrating the evolution of the cart and of the Irish jaunting car; while Professor Dewar concluded the demonstration by repeating his fascinating experiments with liquid air. Sir David Salomons, Bart., showed an important improvement in the stereoscope, which is designed to suit the vision of all persons without straining the eyes, so affording those who are unable to use the ordinary stereoscope the opportunity of appreciating the beautiful and solid effects of this instrument. A series of accurate micrographs taken at a high magnifying power by Mr. T. Andrews were of peculiar interest in illustrating the microscopically visible and tangible micro-flaws almost invariably present in steel railway axles, rails, tyres, propeller-shafts, &c. The importance of the subject is evident from the fact that the presence of "these germs of metallic disease" in steel (mostly due to sulphur and other impurities) greatly influences the deterioration by fatigue of the metal and is a potent factor in inducing sudden fracture of engineering constructions in steel. In connexion with these annual exhibitions of the Royal Society, we are gratified to learn of an important step that is being taken this year which cannot but prove productive of good. The Lords of the Committee of Council on Education have arranged for the public exhibition, in the Western Galleries of the Science Museum at South Kensington, of a number of the objects shown at the Royal Society's *soirée*. The exhibition will remain open to the public for about a fortnight. This is as it should be; the public have always been enabled to view the fruits of the year in the world of art, and why not similarly in the world of science?

THE METROPOLITAN HOSPITAL SUNDAY FUND AND MR. BURDETT.

A SPECIAL meeting of the Council of the Hospital Sunday Fund, held in the old ball-room of the Mansion House on Monday last, was notable for two reasons: it was the first time since His Royal Highness became a vice-patron that the Prince of Wales has attended a meeting of the Fund; and, secondly, it was the occasion of the presentation to Mr. Burdett of a magnificent album containing the portraits of the members of the Council with their autographs, including also that of Her Majesty the Queen as patron of the Fund. Mr. Burdett will, we feel sure, forgive us for giving the primary object of the meeting a second place, because no one will appreciate better than he the prestige which His Royal Highness's name will add to the Fund. The Prince of Wales has ever been ready to help the cause of charity and especially has his willingness manifested itself when the cause of the sick and suffering has been in question. His presence at the festival dinner in aid of the re-endowment of Guy's Hospital on Wednesday is one of the latest displays of His Royal Highness's goodness in this direction, but here in passing we may be allowed to express the hope that that function, important as it was, may not be allowed to overshadow the still more important one which will take place next Sunday. For it must be remembered that Guy's Hospital only represents a portion of the vast metropolis, while the Metropolitan Hospita Sunday Fund is representative of the whole of the hospitals in the great county of London. Last year, as our readers know, the total amount collected by the Fund amounted to

Digitized by Google

some £60,000, a sum which should be maintained this year if the Fund is to efficiently carry on its important work. Towards this amount by the contributions of a few wealthy donors Mr. Burdett raised a sum of £15,000. For this help the Council of the Fund passed a special resolution of thanks to Mr. Burdett, which has been ornamentally emblazoned and enclosed in an album presented to him at the ceremony on Monday. We congratulate Mr. Burdett upon the recognition which he has received from the Council of the Metropolitan Hospital Sunday Fund for the services which he has rendered to the hospital charities of London.

MEDICAL MISSIONARIES.

WHILE congratulating the Church Missionary Society on the success of the medical branch in the mission field, and sympathising with them in their efforts to obtain funds for the further extension of the work carried out by that branch, we regret that one of the speakers at the annual meeting of the Medical Missionary Auxiliary should have seen fit to speak with levity of a profession which renders important aid to the work in which he takes a great interest. Mr. James Munro, C.B., while officiating at one of the society's stations with his son and daughter, felt it desirable that his wife should come out to them, and as in his opinion the evangelical work was of more importance than the medical it was decided that his son should be sent home to fetch his mother. "My daughter and I worked the dispensary ourselves," said Mr. Munro. "I was asked by several medical men whether I did not have any accidents, by which," continued the speaker, "I supposed them to mean deaths." This questionable joke having caused some laughter among the audience the speaker went on to explain that as he was not a professional man he did not have accidents, a remark which led to a fresh outburst of hilarity. We think that Mr. Munro would have shown better taste if he had abstained, even by implication, from casting ridicule on the profession for whose help he was pleading, and we advise him not to make a rule of adding to his other onerous duties the responsibilities of a medical practitioner.

GLOUCESTER SMALL-POX STATISTICS.

THE *Gloucester Chronicle* issued on Saturday last a special edition containing certain data as to the small-pox epidemic at Gloucester up to May 29th. The statistics given are as follows:—

—	Total.	Not vaccinated.	Vaccinated in infancy only.	Uncertain.
Persons attacked ...	1822	639	1056	127
Deaths	396	265	90	41
Proportion of deaths per cent.	21·7	41·4	8·5	32·2

In a note the statement is made that the "uncertain" cases consisted of 17 which were alleged to have been re-vaccinated but on insufficient evidence, 85 which were re-vaccinated after exposure to infection, and 25 about which no information could be obtained. From these figures it appears that the per case mortality of the unvaccinated patients was nearly five times that of the once vaccinated sufferers. If, however, we add the uncertain cases and the deaths among them in their entirety to the cases and deaths in the once vaccinated, we obtain figures as follows—namely, 1183 cases and 131 deaths, yielding a case mortality of 11·1 per cent., and thus still much under one-third that of the unvaccinated cases. These data are given, it should be remembered, while the epidemic is still progressing, and that at the rate of some 50 cases per week; they must therefore be taken only for what they are worth at the moment. And be it noted that no age statistics are here given, an important matter when considering the pros and cons of vaccination in relation to small-pox. But even as they stand the data afford a striking illustration not only of the protective efficacy of vaccination against death by small-pox, but also indirect evidence of the importance of vaccination in warding off attack by small-pox, since it will be seen that not one of the many hundreds of persons recently primarily vaccinated at ages above that of infancy finds place in the statement of attacks.

REMARKABLE INSTANCE OF THE APPRECIATION OF THE PASSAGE OF TIME DURING HYPNOSIS.

AT a meeting of the Society for Psychical Research held on the 5th inst. Dr. Milne Bramwell related the case of a young woman who in a state of hypnosis showed a remarkable power of appreciating the passage of time. The subject of experiment was nineteen years of age and had received an ordinary board school education, during which and since she had not shown any extraordinary capacity of calculation. Before treatment the patient had suffered for about twelve months from functional nervous affections, but at the time of the experiments she was in excellent health. The experiments consisted in suggesting to the patient during hypnosis that she should perform a simple act at the expiration of a certain number of minutes, such as making a cross with a pencil on a piece of paper, and at the same time writing down the time she thought it was when she did this. The interval suggested varied in the course of the experiments from a few hundred to over 20,000 minutes. Sometimes six such suggestions were made at the same time, and starting from different imaginary hours. For example, at four o'clock one day she was asked to fulfil the suggestion in 10,080 minutes, starting from ten o'clock the previous day, &c. Fifty-five such experiments were made, with only two failures. An interesting point was that on awaking, the patient had no recollection of what had been suggested and never complained of headache or gave any indication of nerve exhaustion. It was sometimes arranged that the suggestions should fall due in Dr. Bramwell's house when she was awake or asleep, and the result was always highly satisfactory. On many occasions several independent observers attested the results. The case is to be reported in detail to the International Congress of Psychology, to be held in Munich during the summer.

THE annual dinner of the Army Medical Staff will be held in the Whitehall Rooms of the Hôtel Métropole on Monday next, June 15th, at 7.30 P.M. Gentlemen intending to be present are requested to communicate at their earliest convenience with Surgeon-Lieutenant-Colonel James Hector, the honorary secretary, at 25, Anerley-park, S.E.

A LIFE-SAVING exhibition in aid of the Guy's Hospital Re-endowment Fund will be held at the Central Hall, Holborn, from July 9th to 18th next. The exhibition is promoted by the St. John Ambulance Association, of which the Prince of Wales is president, and by the Life-saving Society, of which the Duke of York is president.

AT the annual dinner of the survivors of the Lucknow garrison, which took place at the Holborn Restaurant on Wednesday evening, Surgeon-General Sir Joseph Fayrer,

Bart., K.C.S.I., Surgeon-Major H. M. Greenhow, and Deputy-Surgeon-General S. B. Partridge, C.I.E., were present.

THE Colonial Office has been informed by telegram from the Governor of Hong-Kong that thirty-four fresh cases of bubonic plague occurred in the colony in the week ending June 9th, and that the number of deaths from the plague during the same period was thirty-five.

THE British Balneological and Climatological Society will hold a conversazione at Limmer's Hotel, Conduit-street, London, W., on Wednesday, June 17th, 1896, at 8.30 P.M., when Dr. C. Theodore Williams will deliver an address on Sea-bathing and the Open-air Treatment of Disease.

AS was generally anticipated, the Queen has appointed Dr. Thomas Barlow, F.R.C.P. Lond., to be Physician to the Household in Ordinary to Her Majesty, in the room of Sir John Russell Reynolds, Bart., deceased.

DIPHTHERIA AND ANTITOXIN AT THE GLASGOW FEVER HOSPITAL.

NEW remedies, whatever be their nature, are received in these days with caution and even with distrust, and this is more particularly the case when these remedies relate to diseases which are known to undergo naturally considerable variation in virulence. The evidence, however, which has now been adduced both at home and abroad as to the efficacy of diphtheria antitoxin must needs go far to convince all open-minded persons that in this method of treatment, though certainly not so potent for good as was once hoped, we have a weapon which if properly used is calculated to diminish in a very considerable degree the case fatality of diphtheria as manifested in recent years. The report of the medical superintendents of the Metropolitan Asylums Board, dealing as it does with a very large number of cases, can leave but little doubt as to the utility of antitoxin, and although it has been deplored by some that the serum was not applied in a more uniform fashion, and that other comparisons were not made, it is clear that the disparity in dosage has taught us very valuable lessons which otherwise might have been lost. Our object at the present moment, however, is to draw attention to another series of cases which, although numerically small as compared with the total of the Metropolitan Asylums Board, nevertheless supports the conclusions there arrived at in a very marked degree. The figures which relate to the Glasgow Fever Hospital, Belvidere, during 1895 are dealt with in a very concise manner by Dr. Ernest Marsh, senior assistant physician to that institution. As in the case of the Metropolitan Asylums Board report, Dr. Marsh takes for his chief standard of comparison the fatality rate of the hospital-treated cases in former years, but it is in a sense unfortunate that reliable statistics in this direction can be only obtained for the years 1890–4 inclusive. During these five years, however, the hospital fatality rates in percentages have been respectively 39·8, 38·8, 37·2, 40·5, and lastly in 1894, when 245 cases were under treatment, 35·5. Before 1890 the annual hospital figures were so small as to afford no reliable data, but the average fatality rate for the years 1871–94, taken together, was 40·4, i.e., 55·4 among those under five and 26·4 among those over five. Coming now to the antitoxin year 1895 we learn that out of 179 cases admitted during the year 137 were treated with antitoxin, while of the remaining 42 cases 38 were so mild as to give rise to no anxiety and 4 were moribund on admission. It will thus be seen that the severe cases only were treated with antitoxin. The antitoxin was as a rule administered shortly after admission in doses of from 10 to 20 c.c.; in 76 cases only one injection was made, while in the remainder additional ones were deemed necessary. Altogether (including 9 treated in 1894) there were 146 cases to whom antitoxin was administered, and of these 4 received doses of 5 c.c., 40 of 10 c.c., 15 of 15 c.c., 38 of 20 c.c., 10 of 25 c.c., 19 of 30 c.c., 17 of from 35 to 40 c.c., 2 of 50 c.c., and 1 of 67 c.c. In all cases simple local treatment and, when necessary, stimulants were used. Of the total 179 admissions during 1895, 25, or 14·0 per cent., died, as compared with a mortality of 35·5 in 1894, the lowest rate then recorded. To what then was this remarkable diminution due? Was it due to an accentuation, a marked accentuation, of the natural fall of the hospital cases observed in 1894, or to some marked difference in the age incidence of the cases? or was it due to the use of antitoxin? To these questions Dr. Marsh furnishes an answer which, if not actually convincing, must be held to carry enormous weight. If the fall in fatality-rate from 35·5 to 14·0 is to be accounted for by a natural decline in the virulence of the disease it may reasonably be expected that something approaching a similar fall will be seen in the home-treated cases. On looking, however, at the figures, it appears that the home-treated cases evinced during 1895, actually an excess in fatality-rate on similar cases during 1893 and 1894.

Year.	Treated at home.			Treated in hospital.			Total.		
	Cases.	Deaths.	Mortality per cent.	Cases.	Deaths.	Mortality per cent.	Cases.	Deaths.	Mortality per cent.
1893	670	145	22·0	153	62	40·0	823	207	25·0
1894	715	167	23·0	245	87	35·0	960	254	26·0
1895	468	114	24·0	179	25	14·0	647	139	22·0

Those, therefore, who contend that the natural variations of the disease explain the sudden drop in case mortality must account for this discrepancy in the home- and hospital-treated cases. Probably the position will be taken up that there has been during the year in question some remarkable shifting of age incidence and that this has been all to the advantage of the hospital cases. Unfortunately the age distribution in the two sets of cases is not given in the report, but in addition to the inherent improbability of this explanation is the fact that the fall has been equally apparent in the cases under five as well as those over five, and in the faucial as well as in the laryngeal cases. There is, however, another method of indicating the value of antitoxin, that is, by a comparison of the tracheotomy cases during 1895 with those of previous years, and probably in a sense this is one of the best comparisons which under the circumstances could be made. Here, again, we are met with the same encouraging results as was the case with the Asylums Board statistics. During 1895 there were 29 cases requiring tracheotomy, as compared with 76 between 1891–92, 42 in 1893, and 23 in 1894. Between 1871 to 1892 a fatality rate per cent. of the tracheotomy cases was 79; in 1893, 76·2; and in 1894, 86·9. In 1895, the antitoxin year, the fatality rate of the tracheotomy cases was but 34·5. What can, then, be the possible explanation of these figures? A sudden drop in the virulence of the disease has already been discussed, and it would seem that a high age incidence among the cases requiring tracheotomy; a deliberate selection of cases with a view to good results, or the introduction of a new and exceptionally skilled operator, are the only feasible explanations. But the reading of these figures alongside those of the Metropolitan Asylums Board is probably sufficient to carry conviction as to the improbability of any of these views being correct. Similarly with regard to the advantages of early treatment the Glasgow figures tell the same tale as the London ones. In the Glasgow figures, however, it is to be regretted that the age incidence of the cases in this connexion is not more fully given—for instance, out of 21 cases treated within forty-eight hours of the onset of the disease there were no deaths; but it is obviously open to the critic to suggest that the age incidence may have had something to do with the results. In the matter of urticarial rashes, abscesses of the seat of inoculation, &c., the Glasgow report tells practically the same tale as did the Asylums Board statistics, and the value of Dr. Marsh's carefully prepared report is most apparent when read side by side with the London figures.

THOMAS WAKLEY,

THE FOUNDER OF "THE LANCET."

A BIOGRAPHY.[1]

CHAPTER XXIII.

A Barren Victory.—The Secession of Mr. William Lawrence.—His Demeanour towards Wakley.—Wakley Continues to "Peg Away."—The Insult to the Medical Officers of the Navy.—The Members Pass Resolutions in the Theatre of the College.—Wakley Treated by the Authorities as a Broiler and Rioter.—A Disgraceful Scene.

THE victory of the Members of the College of Surgeons over their autocratic Council was but a barren one. In obedience to the order of the House of Commons a return was made showing that the College had received from Government £15,000 in June, 1799, for the purchase of the Hunterian Museum (this sum was not granted directly to the College, but to the executors of John Hunter, who, however, in return for it handed over the Hunterian collection to the College); £15,000 in July, 1806, to erect a suitable building to contain the Hunterian Museum; and £12,500 in April, 1810, for building purposes in connexion with the edifice in Lincoln's-inn, a suitable home for the Museum again being mentioned as the chief object of appropriation. The return also showed that £30,000 in addition had been spent by the College in building, the money having been obtained as fees. Passing swiftly over the regulations concerning admission to the museum and certification for examinations, the return next dealt with the source of the income of the College. The years 1825 and 1826 were chosen as types, and the figures furnished showed the income for the years to have been in the gross £7261 16*s.* and £7704 9*s.* respectively. There the return ended, no details of expenditure being given. The document was laid upon the table and no debate ensued. No member of the House was sufficiently interested or sufficiently well-informed to consider it to be his duty to carry the matter further in teeth of the substantial opposition to practical reform that such men as Sir Astley Cooper, Mr. Abernethy, and Sir William Blizzard had been able to secure. The wealth of the College was exposed and its meanness to its commonalty was made no less manifest; but the only people who cared for these things—viz., a reforming section of that commonalty—knew it all before, so that the victory must be considered a barren one. It was a slap in the face for the authorities, but it was not only no rout of them, it did not form even a temporary check to their course.

The committee of Members who had organised the petition and who had hoped such great things from it were sorely disheartened, and almost immediately afterwards they received a great blow by the desertion of Mr. William Lawrence. Mr. Lawrence was a most powerful friend, and could if he chose be a most powerful foe. His mere presence at the assemblies of the reformers, being himself a hospital surgeon, and one of the very class who had most to hope from the prolongation of old abuses, had been of the utmost service; while his ready pen, his eloquence, and his clear brain had served them well, both in the columns of THE LANCET and from the chair at the general meetings. Now the prestige thrown over the movement by his participation in their counsels was gone, while the weight of his talents was thrown into the other scale, for he accepted an invitation from the Council of the College to become one of them. Wakley felt Mr. Lawrence's secession deeply, but the blow was not entirely unexpected. It will be remembered that from the first Mr. Lawrence had proposed milder counsels than suited the more thorough-going of the reformers, but had been always defeated by the general vote. Wakley recognised this, and when the shrill cry of "Traitor" or "Judas" was raised at the news that Mr. Lawrence had agreed to sit on the Council he did not join in it. He deplored Mr. Lawrence's action, but his language was much more measured than that of most of his followers and much milder than was expected by them. Mr. Lawrence was equally studious to preserve an outwardly amicable attitude towards Wakley, the terms of their curious truce having been arranged between them. In fact, they could not fight even if they had wished. Mr. Lawrence had been behind the scenes at the office of THE LANCET for years and knew things that could not be made public without immensely injuring many besides Wakley. All journals have their secrets, and sufficient has been said about the early career of THE LANCET to show that many men must have assisted Wakley in private by giving information, while in public they considered themselves at liberty to stand aloof from the cause of reform. It must be remembered that at most hospitals if a man connected with the institution whether as a student only or as one in authority had been convicted of being on the staff of THE LANCET his conduct would have been regarded by the surgeons as a distinct breach of trust, and he would have lost all chance of promotion at once. So that anonymity was the rule. In a perfect state of affairs this necessity for concealment could not have existed and honourable men need not have been ashamed to hold enlightened opinions; but in the condition of medical politics at that time it was not possible to be over-nice. Wakley had nothing to fear on his own account from any indiscretion of Mr. Lawrence, but he always made his contributors' cause his own cause; and when Mr. Lawrence deserted THE LANCET and the programme of the reformers Wakley felt that the future of many who had helped him was now in the hands of an adversary, one of the detested Council. But Mr. Lawrence, on the other hand, had his lips sealed by self-interest as much as by honour, though be it said Wakley, in common with most thoughtful persons, credited him with the finer motive. Mr. Lawrence had himself written in extraordinarily bitter terms of the leaders of the profession, and had it been known that some of the wittiest and most personal of the strictures that had been passed upon these worthies had been from his pen many among them would not have welcomed him back to the fold. They could not have exhibited even a semblance of friendship towards him. So, as has been said, a curious truce was concluded between Wakley and his late partner in the cause of reform. Mr. Lawrence was understood to esteem Wakley, and to hold his views up to a point, but not to be prepared to follow him to the extreme length that Wakley desired to go. Wakley was content to believe that Mr. Lawrence would still serve the cause of the commonalty even after he had thrown in his lot with the oligarchs, and his references to him were always civil and sincerely regretful.

In spite, however, of the defection of friends, the inaction of Parliament, the turbulence of some would-be reformers and the apathy of others, Wakley kept "pegging away," to use the phrase in which he himself promised that he would never desert the cause of medical reform. Every volume of THE LANCET was prefaced by an editorial statement in which he breathed threats against the Charter of the College. Almost every issue contained some article reflecting upon the government of the College. Now and then he had some little triumph to record, as when the hated back-door

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., XVI., XVII., XVIII., XIX., XX., XXI., and XXII. were published in THE LANCET, Jan. 4th, 11th, 18th, and 25th, Feb. 1st, 8th, 15th, 22nd, and 29th, March 7th, 14th, 21st, and 28th, April 4th, 11th, 18th, and 25th, May 2nd, 16th, 23rd, 30th, and June 6th respectively.

entrance was done away with in 1827, or when the pressure brought by some popular teacher upon the Council to have his certificates officially recognised proved successful to its end. But generally the articles recapituated the complaints that had so often been made, and reading them now we wonder that they did not become wearisome in the ears of those to whom they were addressed, though it is impossible to withhold admiration from their writer's marvellous perseverance. Now it was the senility of certain members of the Council, and now the dirty condition of the library, and now the hauteur of the secretary, Mr. Belfour; but, week in week out, the Council of the College were reminded that they had in Wakley a critic who was frankly inimical to the existent constitution and ever watchful for an opportunity to bring it into discredit. The Council of the College at length redeemed the situation from a monotony of dreary bickering by furnishing Wakley with a legitimate and sensational reason for impugning their methods and manners.

On Feb. 12th, 1831, there appeared in THE LANCET a letter stating that the surgeons of His Majesty's Navy had been notified by circular that they were not to attend the King's levées. The reason for this extraordinary order was not given or even guessed at—and we may anticipate matters by saying that it was issued by the Lords Commissioners of the Admiralty under a grievous official mistake and was almost immediately rescinded. The writer only begged the profession to rally round their insulted brethren and insist upon a proper recognition by the Court of their position as officers and gentlemen. Wakley at once responded. He stigmatised the circular as a deliberate and cold-blooded insult which the profession as a whole was bound to resent, and he urged in THE LANCET that the following Monday at the Royal College of Surgeons would be a good time and place for a public demonstration of sympathy as well as for a public decision upon the steps to be taken towards the annulling of the offensive order. In consequence of this notice a large number of Members attended at the College, the official occasion for which the theatre was open being the delivery of the Hunterian Oration on Hernia by Mr. Anthony White, but the real object of their presence being to publicly protest against the insult inflicted on the naval surgeons by the Admiralty in forbidding them to attend the King's levées. It must be understood that their assembly for such a purpose was an entire and radical innovation, amounting to an assertion that the commonalty and not the Council could decide on the business of the day.

Wakley on entering the College was received with loud cheers and almost immediately rose to protest against the treatment to which "ships'-doctors" had been subjected. In the course of a humorous speech he pointed out that the surgeons of the navy had as much right to be considered officers as those of the army, and moved a resolution that they ought to enjoy the same privileges. Mr. Garland, a very well-known general practitioner and a keen reformer in spirit, seconded the resolution, when Wakley observed that their doings might be considered irregular as they had no chairman; he therefore took upon himself the task of putting the resolution. It was carried with enthusiasm. The second resolution, calling upon the College Council to vindicate the rights and dignity of its Members, was moved by Mr. T. King and having been duly seconded was also carried with acclamation. Mr. King was a popular lecturer on surgery at the General Dispensary in Aldersgate-street and a man of considerable scientific standing.

Just as these resolutions had been passed the officers of the College entered the theatre. Mr. Robert Keate, surgeon to St. George's Hospital, was acting as President for Mr. Headington on the occasion, and Mr. King rose and presented the resolutions to him. The discussion of these was postponed until Mr. White had delivered his oration, the acting President having very distinctly promised that after the oration the Council would listen to what their Members had to say. So poor Mr. White had to read his address to a very impatient audience, who treated his official remarks with scant ceremony, thereby evidently discomposing him. "God knows what to call it ..... a most extraordinary jumble," said Wakley of this oration in the next number of THE LANCET, but Mr. White was undoubtedly placed in a very trying position. When he had at last finished, the acting-President, having conducted certain visitors out, divested himself of his gown, and returning said that as a *member of the Council* he was now ready to hear Mr. King. Wakley said that an agreement to postpone the hearing of their complaints had been made with the acting-President and not with his gown. Sir Astley Cooper tried to cast oil on the waters, spoke highly of the naval surgeons, and characterised the action of the Admiralty as improper. He suggested that the purpose of the Members would be better served by their deputing six of their number to confer with the Council. Mr. Keate, supported by Mr. Thomas, a member of the Council, persisted that he would lay the resolutions before the Council and personally could hear no more on the subject as he was not present in an official position. The meeting terminated by Wakley's remark that the Members had done *their* duty and it only remained for the President and Council to do *theirs*.

The resolutions were duly laid before the Council by Mr. Keate, but were considered "irregular," and the Council "found it impossible" to act upon them. This decision was come to by a majority of 15 to 3, the three being Sir Astley Cooper, Mr. Lawrence, and Mr. Brodie. Wakley considered this a gross breach of confidence. The Members had allowed Mr. White to deliver his oration on the distinct understanding that the President and Council would listen to them afterwards. At the close of the oration the acting-President found himself unable to do more than convey a message to the Council, having hung up his official position in the ante-room with his gown—a piece of quibbling that had been received by the meeting with hearty disapprobation. Consequently, in the following week Wakley again begged the profession to attend at the College and decide what course should be taken to compel the Council to espouse the cause of the oppressed naval officers. The Members were enjoined to assemble at the College at three o'clock, at which hour the doors of the theatre would be open in preparation for the next Hunterian lecture at four.

Immediately upon this invitation being given by Wakley the Council issued a notice in the morning papers that the doors of the College would be opened at 3.45, and not until then, and that no public discussions would be allowed in the theatre of the College either upon that or any other occasion. Circular notices to this effect were also posted to some of the metropolitan Members. The Members, however, either being ignorant of the Council's action or believing it to be a ruse, arrived in great force, to the number of three or four hundred. The porter did his duty to his employers and refused to admit anybody until 3.45, in spite of the very inclement weather. At about twenty minutes to four Wakley arrived and demanded admission, but the porter stuck to his instructions, only exceeding them by making a special attempt to exclude the Editor of THE LANCET. At twelve minutes to four the doors were thrown open, and no sooner had the theatre been filled in every part, which occupied but a minute or two, than Wakley was called for on every side. He rose to speak in a scene of confusion and uproar which beggars description. The majority of the meeting was with him, but a small opposition was noisy and demonstrative. Wakley declared that nothing need now be done until the President's arrival, when the officers of the College must be asked by the

Digitized by Google

assembled Members who was responsible for the advertisement and circular forbidding them to assemble in their own College.

At four o'clock the President, Council, and a *posse* of Bow-street officers entered the theatre. Wakley rose holding the circular in his hand, and tried to ask whether it was an official document issued by the Council. The President, Dr. Morson, and Mr. King, as well as Mr. Guthrie (a member of the Council), tried to make themselves heard without avail. The disorder seemed wildest in the immediate neighbourhood of Wakley, who remained on his feet without speaking, the centre of a circle of applauding supporters. A Bow-street officer was sent to order him out. The surrounding Members would have rallied to his aid, but Wakley forbade them, saying that the Council had not the least power to remove him. He informed the officer of this fact, who returned to the Council saying, "Mr. Wakley knows perfectly well what he's about." The Council were exasperated, and one gentleman went so far as to suggest the use of the constables' staves. The uproar still continued and at last the President rose and left the theatre, being followed by the Council and visitors. Wakley then addressed the meeting, imploring them to preserve quiet behaviour. He proposed that they should put themselves in order by electing a chairman, and suggested Mr. George Walker, a surgeon at Sheerness and a very senior Member. Mr. Walker was unanimously elected and Wakley at once continued his speech. He observed that they "had not listened to a lecture on *hernia*, but that *rupture* was a very appropriate subject on such an occasion." He asked the Members whether they did not consider that he had been right in enquiring of the Council whether the precious document he held in his hand had emanated from them officially; he described it as one of the most extraordinary pieces of composition he had ever seen, and suggested that it must be the work of Mr. Belfour's cook. He said he would not move a vote of censure on the Council for the indignities to which he and his brother Members had been subjected because he really thought that vote had already been as good as passed. He described for the meeting the gross insult put upon the naval surgeons by the Admiralty, and finally moved a resolution that the Members deeply regretted the unsympathetic attitude of the Council as shown by the fact that they had refused to notice the resolutions of the Members passed for their consideration at the previous meeting. "This refusal," said Wakley, "is another added to the already innumerable existing proofs that the President and Council are alike indifferent to the honour, happiness, and respectability of the commonalty of this chartered College." The resolution was seconded by a Mr. Complin and carried with only two dissentients.

A few moments later Mr. Belfour, the secretary of the College, and the person whose name had been appended to the offending circular, entered the theatre and handed to Wakley a paper bearing the following words: "Mr. Wakley, you are required by the President and Council to quit the theatre." Wakley refused point blank, when a similar order to the Members, written large and pinned to a board, was held up over the lecturer's desk. No one moved. Suddenly a number of Bow-street officers rushed into the theatre and making for Wakley seized him by the collar, arms, and legs, and proceeded to expel him by force from the building. The surrounding Members ran to his assistance and a tug of war ensued, Wakley playing the somewhat unpopular *rôle* of rope (his own description). While he was thus stretched out a Bow-street officer aimed a blow at his head with a truncheon. This providentially missed him and his struggles were so fierce as to throw himself and half-a-dozen persons down several benches to the floor of the theatre. The fighting might have been prolonged in spite of the nature of the odds, for Wakley was a man of great strength and large frame and an expert boxer and wrestler, but it was not his desire to continue the brawl. He consented to leave the building, and urged his friends to forego further resistance. On getting outside the officers released their grip when Wakley at once ordered them to take the officer Ledbitter, who had aimed the cowardly blow at him, into custody. This they refused to do, but at last two Bow-street officers to whom the previous occurrences were unknown were fetched who complied. The procession, consisting of the Bow-street officers, the arrested man and his custodian, Wakley with his clothes hanging on him in rags, and a body of sympathetic followers, made its way through Covent-garden accompanied by an enormous and uproarious crowd to Bow-street, where at seven in the evening Wakley charged his assailant before the chief magistrate, Sir Richard Birnie.

In the meanwhile the Members who had remained in the theatre proceeded with the business for which Wakley had convoked them. They passed a resolution that three of their number should form a deputation to the Lord Chamberlain (the Duke of Devonshire) to point out to his Grace the invidiousness of the position in which the naval medical officers had been placed by their exclusion from the levees of the Sailor-King and they selected to represent them Messrs. Wakley, Walker, and King.

(To be continued.)

THE SOUDAN CAMPAIGN.

As we surmised last week from the signs that were apparent in the Nile expeditionary force, things have recently assumed a far more active phase. With regard to the political or financial aspects of the Egyptian question we have, of course, nothing whatever to do; but we suppose all will be agreed that once an expedition of this kind has been undertaken the sooner and more decisively it is carried out the better. A forward movement has now taken place and a most successful attack has been made upon the Dervishes, who were surprised and defeated by the Egyptian army and driven out of their camp at Firket with considerable loss, and that station, with its camp, stores and equipment, arms, camels, horses, and provisions, has been captured by a force led by British officers under the command of the Sirdar, Sir H. Kitchener. The attack appears to have been admirably conceived and brilliantly executed, and the moral effect of it cannot fail to be great. It is satisfactory in the first place to learn that nothing could have been better than the behaviour of the troops, both Soudanese and Egyptians, and, in the second, the impression which this early exhibition of our power is likely to create in the minds of the Dervishes must not be lost sight of, to say nothing of the effect it will probably have upon the native tribes and population who may be wavering as to the side they will take in the campaign. As regards the quality of the Soudanese or black troops there has never been any doubt, they are born fighters; brave and well-disciplined, they have always given a good account of themselves; the doubt was with regard to the Egyptian soldiers, who, notwithstanding that they are men of fine physique and admirably drilled and disciplined, have not hitherto been remarkable for their display of courage and steadiness in actual war. On this occasion, however, everyone seems to be agreed that they fought well, and that the Egyptian army as it exists at the present time is a very different force indeed from what it was. Under British officers and British leadership Egyptian soldiers have acquired the requisite spirit and confidence to make them effective fighting material. The most advanced post of the Dervishes was at Firket on the banks of the Nile about twenty miles from Akasheh. The main body of the Nile expeditionary force having previously made a heavy march from Akasheh on the night of the 6th inst., attacked the enemy's position early on the following morning, and in about an hour and a half from the commencement of the fight the Dervishes were in full flight. Our casualties

Digitized by Google

were trifling. One British officer, Captain Legge, of the 20th Hussars, received a sword wound. The Egyptian army had twenty killed and eighty wounded; of the latter eight are Egyptian officers. A hospital has been established and the wounded are reported to be doing well. The Dervish losses, which include the Emir Hammuda, who commanded, and several other emirs, are estimated to amount altogether to 800 or 1000. The number of prisoners taken is also large. Fortunately the weather during these operations was rather cooler than usual. The Egyptian army is reported to be well supplied and the medical arrangements have so far worked most satisfactorily. It is to be hoped that the success that has been achieved may facilitate our subsequent advance on Dongola, and that we may be sooner within measurable distance of the end of the campaign than was at first anticipated. Once peace and a settled government are established trade will begin to revive, railways will be constructed, and every attempt will be made to establish free intercourse and communication between the inhabitants of the Nile and desert and those of Lower Egypt.

According to the latest telegraphic intelligence a body of mounted troops, under the command of Colonel Burn Murdoch, have advanced from Firket thirty miles across the desert to Suarda, on the Nile, and have occupied that place. Infantry are being rapidly pushed on to hold Suarda, which is a strong and very valuable position. The Dervishes were evidently surprised by the Egyptian cavalry force. The entire Dervish camp has been captured with a great quantity of supplies, and a number of prisoners have been taken. This must prove a serious blow to the Dervishes. The campaign has evidently been pushed on so far with great energy and success.

THE OBLIGATIONS OF THE GENERAL MEDICAL COUNCIL, MEDICAL SCHOOLS, AND CORPORATIONS IN RELATION TO THE RIGHTS OF MEDICAL MEN.

A MEETING (adjourned from May 15th) of the Select Committee of the Civil Rights Defence Committee was held on May 22nd at the residence of Mr. Victor Horsley, Mr. Timothy Holmes being in the chair.

The minutes of the last meeting were read, adopted, and signed by the chairman.

General Graham brought up the letter to the Master of the Society of Apothecaries duly signed by the members of this Committee (see below), and reported that the Master had very kindly consented to receive Mr. Anderson and himself (the speaker) on Tuesday, May 26th.

A draft letter to the President and members of the General Medical Council was considered and adopted for signature by the members of the Select Committee.

Mr. Rivington inquired whether it would not be well to propose definite measures to the General Medical Council, and especially in relation to the Privy Council appeals, since the relations of the General Medical Council to the Privy Council in the administration of the Medical Acts, and presumably in maintaining them inviolate, are direct and intimate.

The Chairman said he understood the most urgent question was the appeal to the House of Lords in Anderson *v.* Gorrie and Others, and that as that decision destroys the rights of medical men under the Medical Acts the coöperation of the General Medical Council by appointment of representatives to, and by coöperation with, this Committee, and even by contribution from its funds in support of the Medical Acts, might reasonably be asked.

Mr. Anderson said that Lord Stamford's letter which the Committee was supporting invited the General Medical Council to receive a deputation, to appoint representatives to the Civil Rights Defence Committee, and to coöperate in such other ways as might be considered advisable. After discussion it was resolved to await the reply of the General Medical Council to this letter and to that of the Earl of Stamford.

On consideration of a letter inviting independent representations from the constituent bodies of the Civil Rights Defence Committee in support of the invitation to the General Medical Council, and asking the British Medical Association to arrange a deputation to the General Medical Council, it was resolved to postpone dealing with these proposed measures till a reply should be received to the present invitation to the General Medical Council.

Opinion of counsel was brought up by General Graham fully supporting the views and action taken by the committee and that the judgment was voidable, on the precedent of Dimes *v.* Grand Junction Canal Co. (3 H. L.Cas); that the court, though it had a discretion, had under the circumstances the power and the duty to set aside the judgment and hear the appeal; that Mr. Anderson was entitled to have the orders the court made drawn up; that by refusing to draw them up the court embarrasses Mr. Anderson in his appeal to the House of Lords.

Mr. Rivington laid on the table THE LANCET of May 23rd, with a very full report of the meeting of May 15th, and the meeting expressed its sense of the great advantage to the cause of such full publication of the proceedings.

With a vote of thanks to Mr. Holmes for his valuable services in the chair the meeting adjourned *sine die*, to be convened by special notice by the secretarial committee.

The following is a copy of the letter to the Master of the Society of Apothecaries mentioned above:—

5, Mitre-court, Temple, E.C., May 16th, 1896.

To the Master of the Worshipful Society of Apothecaries of London.

SIR,—We beg to address you as members of the Civil Rights Defence Committee and of the Select Committee to which has been referred the question of the obligations of the medical schools and corporations and General Medical Council in relation to the rights of medical men held out as inducements to young men to enter the profession.

Of all these rights Mr. Anderson, and with him all medical men, are deprived by the judgments pronounced in his case, the facts of which are already fully before you.

We desire, therefore, to support Mr. Anderson's application to your worshipful society to take part in defending the rights thus violated and to lend your powerful influence in enlisting in that defence the aid of other worshipful companies of the City of London whose charters are endangered by the infringement of your own in Mr. Anderson's case, and who, we feel every confidence, will readily respond to an appeal from you to unite in this defence of your ancient rights and liberties.

The circumstances of the case are so extraordinary that we feel sure on investigation your worshipful society will find our representations fully justified, and that not only will your sense of justice and regard for the dignity of your rights violated in the violation of your Licence to Mr. Anderson, but your sympathy for him as a grievously oppressed and injured man be fully enlisted in our support.

We beg to cordially support Lord Stamford's invitation to you of Nov. 21st, 1895, to appoint representatives to our Committee, on which we shall heartily welcome their coöperation.

General Graham and Mr. Anderson have been requested, with your permission, to convey this letter to you on our behalf.

We have the honour to remain, Sir, your obedient servants,

TIMOTHY HOLMES, M.A. Cantab., F.R.C.S.,
Chairman of Select Committee on Medical Defence, representative of Association of Fellows of the Royal College of Surgeons of England.
WALTER RIVINGTON, M.A., M.B., M.S. Lond., F.R.C.S.,
J. WARD COUSINS, M.D. Lond., F.R.C.S. Eng.,
Representing the Royal College of Surgeons of England.
J. WARD COUSINS, President of Council,
HENRY T. BUTLIN, Treasurer,
Representing the British Medical Association.
GEORGE D. POLLOCK, F.R.C.S.,
FREDERICK J. GANT, F.R.C.S.,
H. PERCY DUNN, F.R.C.S.,
Representing the Association of Fellows of the College of Surgeons.
VICTOR HORSLEY, F.R.S., F.R.C.S., President of the Medical Defence Union,
J. ALFRED MASTERS, M.D., M.R.C.P. Lond., Treasurer of the Medical Defence Union,
Representing the Medical Defence Union.
E. G. YOUNGER, M.D., M.R.C.P.,
J. ERNEST BULLOCK, M.D.,
Representing the West London Divisions of the London and Counties Medical Protection Society.

The following resolution was unanimously passed at a meeting of the Barbados Branch of the British Medical Association held on April 10th, 1896:—

"That this branch of the British Medical Association adopts the reports of the Civil Rights Defence Committee on the case of Mr. R. B. Anderson, F.R.C.S. Eng., as correctly stating the professional and civil rights involved in the injuries done to Mr. Anderson; identifies itself with the Committee in the measures adopted in defence of those rights; and unites with the Committee in cordially inviting Her Majesty's Ministers, Members of Parliament and other public men, the Guilds of the city of London, the General Council of Medical Education and Registration, the great professional corporations and the medical schools of the United Kingdom, and especially the University of London, the Royal College of Physicians of London, the Worshipful Society of Apothecaries, and the St. Mary's Hospital School, to unite with the Committee in defence of rights essential to the practice of the medical profession as a means of livelihood."

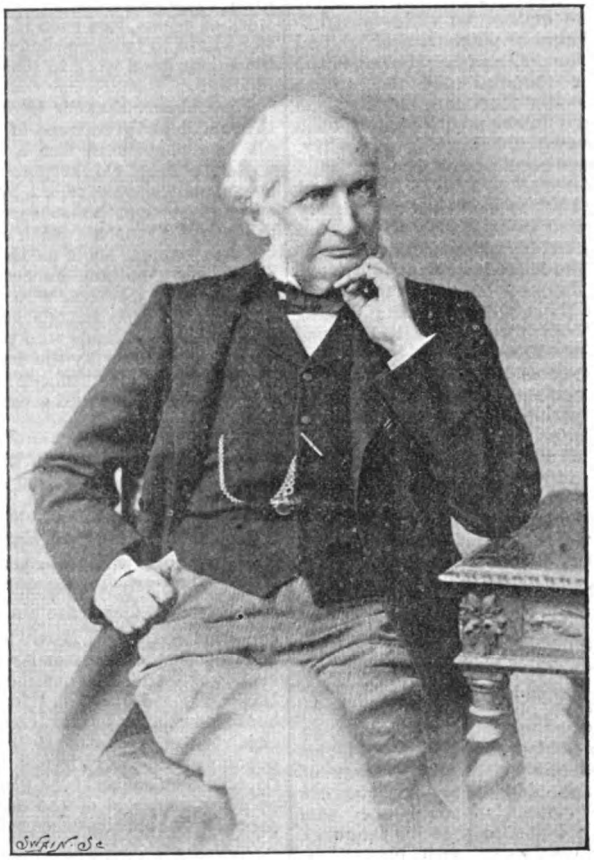
Obituary.

SIR GEORGE JOHNSON, M.D. LOND., F.R.C.P. LOND., F.R.S.,

PHYSICIAN EXTRAORDINARY TO HER MAJESTY THE QUEEN, CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL, &C., &C.

WE briefly announced last week the death of Sir George Johnson, which occurred at his residence, 11, Savile-row, on Wednesday, June 3rd. For many years he had suffered from paralysis agitans, and some five or six years ago his condition had caused considerable anxiety to his friends, but more recently he had been much better, and had been able to resume practice and literary work, and even on Monday, June 1st, he had spent the morning writing the memorandum, which we print in another page, on the treatment of cholera, the manuscript showing remarkably few corrections or alterations and exhibiting no indication of the approaching end. An hour after returning home in the afternoon he was found on the floor unconscious and was thought to have had a fainting fit; but when his colleague, Dr. Tirard, arrived the gravity of the condition, right hemiplegia with aphasia, was noted, a diagnosis confirmed later when he was seen again by him in consultation with Sir Alfred Garrod. Consciousness was partially regained on Monday and Tuesday, but late on Tuesday night the pulse became irregular and intermittent and he became less responsive; coma supervened at midday on the 3rd, and he passed away so peacefully that it was difficult at first to realise that the end had come.



SIR GEORGE JOHNSON, M.D., F.R.S.,
PHYSICIAN EXTRAORDINARY TO THE QUEEN.

George Johnson was born in November, 1818, at Goudhurst in Kent, and was educated at the grammar school there. His choice of the practice of medicine as a profession was the result of an accident. His maternal uncle was a general practitioner at Cranbrook in Kent, and in the early part of 1837 his arm was broken by a fall from his horse. He then asked young George Johnson to stay with him for a few weeks and drive him in his gig. At the end of six weeks Johnson decided to relinquish the plans that had been made for his future and to join his uncle as an apprentice. His father warned him that he must not expect to meet with the same amount of success, but young Johnson replied that he would be content with a modest income. After remaining two and a half years with his uncle he entered the medical department of King's College, London, in October, 1839. His college career was a highly distinguished one. He was awarded prizes in anatomy, chemistry, physiology, and materia medica, and at the end of his third winter session he obtained the first prizes in medicine, surgery, and midwifery, the first Warneford prize, and the King's College Medical Society's prize for an essay on "Auscultation and Percussion." He was also awarded the senior scholarship which had then just been founded, and he was elected an Associate of King's College. At King's College Hospital he served as clinical clerk to Dr. Todd and dresser to Sir William Ferguson. At the end of his college course he held in succession the offices of house physician and house surgeon to the hospital. In 1841 he passed the first M.B. London in the first class, and in 1842 the second M.B., again in the first class, and received the scholarship and medal in Physiology and Comparative Anatomy. In 1844 he took his M.D. degree at the London University. In 1846 he became a Member of the Royal College of Physicians of London and in 1850 was elected a Fellow of that College. In the same year he married Charlotte Elizabeth, the youngest daughter of the late Lieutenant White of Addington; he was left a widower with five children in 1860. At the Royal College of Physicians of London he served the offices of Examiner in Medicine, Censor, Councillor, Goulstonian Lecturer, Materia Medica Lecturer, Lumleian Lecturer, Harveian Lecturer, and Vice-President. In 1862 he was appointed a Senator of the University of London, and in 1872 he was elected a Fellow of the Royal Society. In connexion with his work at King's College he was the first to receive in 1843 the appointment of resident medical tutor, an office which he held for seven years. In 1847 he was appointed assistant physician of King's College Hospital and in 1856 he became a full physician. In 1857 he succeeded Dr. Boyle as Professor of Materia Medica and Therapeutics, a post he retained until 1863, when he succeeded Dr. George Budd in the Professorship of the Principles and Practice of Medicine. In 1876 he resigned the chair of Medicine in consequence of the pressure of private work, and was appointed Professor of Clinical Medicine. When in 1886 he resigned that office he was elected by the Council Emeritus Professor of Clinical Medicine and consulting physician to King's College Hospital. In 1876 the Council of the Royal College of Surgeons of England appointed him one of the examiners in medicine, but he was unable to fulfil the duties of this office, as they interfered with those of the Senior Censorship of the Royal College of Physicians of London. For eighteen years he was physician to the Equitable Assurance Office. In 1883 Dr. Johnson was appointed by the Prince of Wales consulting physician to the Royal College of Music. In 1884 he was elected President of the Royal Medical and Chirurgical Society. In 1885 the committee of the Athenæum Club paid him the compliment of electing him a member of the club under the rule which provides for the annual introduction of a certain number of persons of distinguished eminence in science, literature, the arts, or for public services. In 1888 past and present students united with other friends in presenting him with his portrait painted by Mr. Frank Holl, R.A. The public presentation was made by Sir Joseph Lister in the large theatre at King's College in the presence of numerous of his former colleagues and friends, and the scene was one which will long be remembered both for the kindly tribute of praise paid by Sir Joseph Lister and for the graceful and emotional response made by Dr. Johnson. In 1889 he was made a Physician Extraordinary to the Queen, and he received the honour of knighthood in 1892.

The following is the list of his principal contributions to medical literature:—"On Diseases of the Kidney: their

Digitized by Google

Pathology, Diagnosis, and Treatment," published in 1852; "Lectures on Bright's Disease," 1873; "Epidemic Diarrhœa and Cholera," 1855; "Notes on Cholera," 1866; and "The Laryngoscope: Directions for its Use and Practical Illustrations of its Value," 1864. He also contributed largely to the current medical periodicals, and assisted Sir Thomas Watson in revising the last edition of his famous "Lectures on the Principles and Practice of Medicine." Referring to his coadjutor, and expressing his obligations to him in an epilogue, Sir Thomas Watson says of him, "I will only say that I think him unsurpassed for accomplishments and ability in his vocation. King's College may well be proud of him." It is generally acknowledged that Sir George Johnson's most important contributions to medical science are—"Notes Relating to Bright's Disease of the Kidneys," "The Pathology and Treatment of Cholera," and "The Diagnosis and Treatment of Diseases of the Throat by the Aid of the Laryngoscope." In 1884 he published a "Defence of Harvey as the Discoverer of the Circulation of the Blood." This defence was a reply to certain criticisms which had been evoked by his Harveian Oration of 1882. It may be remembered that in the oration he endeavoured to vindicate Harvey from the charge of plagiarism which had been made by some Italian professors, and he referred to the voluminous work by Professor Ceradini and also to an oration by Professor Scalzi. His Harveian Oration was attacked by Professor Scalzi, and Johnson with warmth once more resumed his defence of Harvey and Harvey's originality. In 1887, after relinquishing active hospital work, he published his "Medical Lectures and Essays," and in 1889 followed "An Essay on Asphyxia." In 1895 he published a "History of the Cholera Controversy," and in 1896 a small book on "The Pathology of the Contracted Granular Kidney."

We have permission to use the following remarks written some years ago by Sir George Johnson himself. They have a bearing upon his work, and those who knew him, either personally or by repute, will probably read them with interest. "The most anxious period of my life was that in which I first entered upon the controversy as to the pathology and treatment of cholera after the epidemic of 1854. My friend Dr. Todd knew that I was preparing to publish particulars of the cases which I had treated by evacuants, together with my views as to the nature of choleraic collapse. He said to me, 'I believe that in the main you are right, but you will not convince the profession that you are, and in the attempt to do so you will suffer serious harm to your reputation and your prospects. I therefore advise you to publish no more on the subject.' I told him that I could not act upon his advice, and that with a firm belief that I was right I would not shrink from contending for what I held to be true, however unpopular it might be. I have never regretted that I did not accept Dr. Todd's well-meant advice, for I am persuaded that the time will come when Sir Thomas Watson's judgment of my cholera theories and practice will be universally acknowledged to have been just." In these words, which to a large extent he repeated in his last publication on the "History of the Cholera Controversy," may be found the clue to much of Johnson's line of thought. Many of his writings provoked opposition, and it is characteristic that he never shrank from contention with one who differed from him in opinion; and also that his language and his arguments gained in strength with opposition. In the height of controversy he frequently employed terms which, perhaps, to a certain extent are to be regretted. In fact, to him the scientific world was divided into two classes—those who agreed with him and those who differed; and his language in dealing with most of the controversies aroused by his theories may sometimes seem to us more powerful than the occasion appeared to demand. His defence of the hypertrophy of the small arteries in Bright's disease was very forcible; and on one occasion—in 1876—an unfortunate dispute arose between him and Sir William Gull over a point of professional etiquette connected with the "Balham case." This question was referred to the Royal College of Physicians of London, and although the decision was given in Dr. Johnson's favour a great deal of ill-feeling was aroused. In his "Medical Lectures and Essays" many of the strong expressions of younger days were toned down, although in forcible and clear language he maintained the views expressed earlier in life. There is throughout this book ample evidence that the author had thought much upon the subjects about which he had formerly written. His views are expressed here and there in more guarded words; but in some instances he seems also to have taken pains to set them before the reader armed and ready—nay, even anxious—for the fight. There have been those who have blamed Dr. Johnson for the warmth and the pugnacity of his style of literary diction, but it may be doubted whether any really good work has been done in any profession without an abundance of hard hitting. In recent years men have been more tender in avoiding wounding the susceptibilities of others, but an enthusiastic belief in the truth of what he teaches is apt to lure the teacher into the hot places of controversy. All Johnson's convictions he taught with an enthusiasm which showed how fully he relied upon the accuracy of his statements and upon the importance of what he taught. In the "Medical Lectures and Essays" he appeared to write with the calmness of one who recognises the great truth that work of all kinds in the long run must take its proper place in the estimation of thinking men, and will be valued by them according to the truth which time has shown it to possess. To this tribunal he was, we think, willing to leave the last word concerning much of what he had written and taught. Beyond a doubt his work, even when most controversial, was most stimulating to the work of others, and even if some of his theories and observations have to be somewhat modified, they will none the less have done good work in rousing enthusiasm and encouraging inquiry.

We feel sure that Sir George Johnson's life as written in the medical literature of the past fifty years will lead all to recognise in him a competent teacher, a vigorous writer, a deep thinker, and one who when fighting most strenuously was impelled by an earnest desire to convince others of what he so earnestly believed to be the truth. Sir George Johnson's death severs largely the connexion with historic names, such as those of Sir Thomas Watson, Dr. Todd, Sir William Ferguson, Sir William Bowman, Dr. Bristowe, and others, who were his firm friends. Though many of his early friends have passed away, the number of admirers and friends who yet remain to respect his memory was amply shown by the large and representative gathering at St. James's Church, Piccadilly, when the last public tribute of affection and esteem was shown on Monday.

KENNETH McLAREN, M.B., L.R.C.P. LOND., M.R.C.S. ENG.

THE death of Dr. Kenneth McLaren took place at his residence, Newport-road, Cardiff, on May 29th. The deceased gentleman was thirty-five years of age and had been in practice in Cardiff for six years. About a week previously he contracted a cold and acute pneumonia followed. Dr. McLaren was educated at St. Bartholomew's Hospital and graduated M.B. of London University in 1890, having two years previously taken the qualifications of M.R.C.S. Eng., and L.R.C.P. Lond. He had formerly held the appointments of house surgeon to St. Bartholomew's Hospital and house physician to the Royal Free Hospital. Dr. McLaren was extremely popular and during his residence in Cardiff had made many friends. The funeral took place on June 1st and was attended by many members of the medical profession as well as residents, by whom the deceased was much respected.

T. CANNING HUNTER, L.R.C.P. EDIN.

WE regret to announce the death of Mr. T. Canning Hunter, Pontypridd, the eldest son of Mr. R. C. Hunter, J.P., who has practised in the town for over thirty years, which took place after a brief illness early on the morning of June 7th. The deceased, who was only twenty-eight years of age, a week previously complained of feeling unwell and went to bed. A severe attack of pneumonia set in, and he was in a very critical condition during the week. All that medical skill could do was done for him by Mr. Jenkins, Pontypridd; Dr. Sheen, Cardiff; and Mr. Evan Jones, Aberdare. On the morning of the 6th he rallied slightly, but a change for the worse again occurred, and shortly after midnight he passed peacefully away, having lost consciousness half an hour before the end came. Mr. Hunter had a bright, cheerful disposition, and his untimely death cuts short a career which gave every promise of success. He was educated at Mr. Shewbrook's school, Monckton House, Cardiff, and finally in Scotland, and last January he qualified as a physician and surgeon at Edinburgh. The funeral took

Digitized by Google

place on Wednesday, when the remains were laid to rest in Glyntaff Cemetery.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. J. W. Scott, Professor of Materia Medica in the Western Reserve University, Cleveland, U.S. Dr. J. Lojo y Batalla, Professor of Children's Diseases in Santiago (Spain). Dr. Nicolás Montells Bohigas, Professor of Clinical Surgery in Saragossa. Dr. J. A. Stoltz formerly Professor of Midwifery and Gynæcology in the Nancy Medical Faculty.

THE ASSOCIATION OF BRITISH POSTAL MEDICAL OFFICERS.

THERE was a very numerous and representative gathering at the fourth annual dinner of the Association of British Postal Medical Officers, which was held in the Whitehall Rooms of the Hôtel Métropole on May 19th. The event proved to be a successful one. Mr. Matthew Halton, J.P., President, occu ied the chair and there were also present: Sir Walter Foster, M.P., Sir Thomas Roe, ex-M.P., Sir Dyce Duckworth, Sir Robert Hunter, solicitor to the Post Office; Mr. Lewin Hill, third secretary to the Post Office; Mr. Baillie Gage, solicitor to the Post Office, Dublin; Dr. Farquharson, M.P., Mr. Alfred Arnold, M.P., Dr. Thorne Thorne, C.B., Dr. Henry Fitz-Gibbon, Dr. Walton Browne, Dr. W. Dougan, Mr. Frank Iliffe, Dr. Ritchie Giddings (hon. secretary), Mr. Bertram Thornton, J.P., Dr. Leonard Adeney, J.P., Dr. West Symes, Mr. McVeagh, Surgeon-Lieutenant-Colonel Murray, Captain H. Berkeley, R.N., Dr. Matthew Coates, Dr. I. Brown, Mr. Poole Lansdown, Dr. Domett Stone, Mr. J. W. Burbidge, Mr. Philip Jones, Dr. W. Taylor, Mr. C. Pemberton, Mr. Picton Phillips, Dr. Thomas Higgs, Dr. Richard Paramore, Dr. James Oliver, Mr. Biddulph Goss, Dr. Ridley Hilder, Mr. W. B. Hallowes, Mr. S. Evans, and many others. The Duke of Norfolk, Postmaster-General, wrote expressing regret at his inability to be present, and similar letters were received from Mr. Cresswell (secretary to the Post Office, Dublin), Sir John Lubbock, M.P., Dr. A. Whitelegge (Chief Inspector of Factories), Mr. Luke Fildes, R.A., Mr. Alma Tadema, R.A., &c.

The loyal toasts having been duly honoured, Dr. Paramore proposed "The Army, Navy, and Reserve Forces," to which Captain Henry Berkeley, R.N., Surgeon-Lieutenant-Colonel Murray, and Surgeon-Lieutenant-Colonel Phillips replied. Sir Dyce Duckworth then in a brilliant speech proposed "The Houses of Parliament." Sir Walter Foster, in responding, said Sir Dyce Duckworth had said, "Thank God we have a House of Lords." His feeling would have been considerably more intense if we had arrived at the stage of civilisation in which we had life peerages and medical men, on account of their intellectual and social qualifications and their self-sacrifice for the good of humanity, found a place in the House of Lords. The medical men connected with the postal service had done wisely and well in organising themselves. They had under their charge in various parts of the kingdom one of the most deserving class of public servants. They had grave and reasonable duties to perform, and they should frame such a policy for themselves as would tend to the better performance of their duties and the elevation of the class to which they belonged. They could then raise the postal medical officers of this kingdom to that position which they ought to enjoy as a very important part of the Civil Service. No men in the Civil Service deserved higher honours than its medical men when they did their work honestly and well. He saw around him men receiving distinction for services infinitely smaller than the services rendered to the State by the medical profession, and it was in a combination such as this that they would finally win their way to that just recognition of their work which was the duty owed to them by the State for long and faithful service. The association had only been in existence for some four years, but he believed there was a great future before British postal medical officers if they acted together for the common good and the elevation of their calling, which was, after all, for the good of humanity. The medical profession was of professions the most neglected among politicians; they were carrying on a war against the greatest enemy of humanity, but their laurels were not given them by the State, but by their approving consciences. He hoped the time would speedily come when the State would recognise as worthy of the highest honour medical men whose life aims were those of preventive medicine.

Mr. Alfred Arnold, M.P., having also replied, Mr. Bertram Thornton, J.P., proposed "The Postmaster-General, the Secretary, and other Officers of the Department." Mr. Lewin Hill and Sir Robert Hunter replied, the former remarking that he did not consider that the present severe educational test was the most reliable one for securing efficient recruits for the postal service, in whom a thorough aptitude for business was an essential.

Sir Thomas Roe proposed "The Association of British Postal Medical Officers." He said this association had been organised not for purposes allied to trades unionism, but for the purpose of joining together all the members of the medical profession connected with the postal service in the United Kingdom, so that they could compare notes and see that any advantage, however small, that might have been discovered in one individual district should be conferred upon every district connected with the association. He considered that the association merited the support and sympathy of the Department and of all public men generally. Dr. Henry Fitz-Gibbon responded.

Dr. Farquharson, M.P., in proposing "State Medicine," emphasised the necessity and importance of having one special department in the State duly represented in the Government, whose duty it should be to deal with all medical questions of every kind that may arise instead of the diffuse and unsatisfactory arrangement which obtains at the present time. Dr. Thorne Thorne replied.

"The Chairman," proposed by Dr. Walton Browne in a felicitous speech, was most cordially received, and a very enjoyable evening terminated by the President toasting "The Secretary," in doing which he remarked that the two reports which had been framed by him for the association during the past year for presentation to Lord Tweedmouth's Committee, the one dealing with several questions concerning the general health of postal employés and the other with the average sanitary condition of the post-offices of the country, would be memorable incidents in the history of their association.

The annual general meeting of the association, which has made extensive strides during the past year, was held in the hotel in the morning, when many matters were under discussion by a large number of the members from all parts of the kingdom. The following executive was elected for the ensuing year:—President: Dr. Henry Fitz-Gibbon, Dublin. Vice-Presidents: Dr. Watson, Manchester; Mr. Iliffe, Derby; and Mr. Halton, Barnsley. Hon. Secretary for Scotland: Dr. W. Dougan, Glasgow. Hon. Secretary for Ireland: Dr. Walton Browne, Belfast. Hon. General Secretary and Treasurer: Dr. Ritchie Giddings, Nottingham. Committee: Mr. McVeagh, Coventry; Mr. Thornton, Margate; Mr. Walker, Middlesbrough; Dr. Coates, London; Dr. Paramore, London; Dr. Taylor, Cardiff; and Mr. Lansdown, Bristol. Auditors: Dr. West Symes, Halifax; and Dr. Dougan, Glasgow.

DEATH CERTIFICATION.

THE following report was circulated amongst the members of the Liverpool Medical Institution and approved by them at the last meeting of the council of that institution.

LIVERPOOL MEDICAL INSTITUTION.

At a meeting held on April 18th, 1895, a sub-committee was appointed to consider the recommendations of the Select Committee of the House of Commons on Death Certification, and to draw up resolutions thereon, to be submitted to a future meeting of the Institution.

The sub-committee consisted of—

Dr. William Carter, Chairman.
Dr. James Barr, Dr. E. W. Hope, Mr. F. W. Lowndes, Dr. W. Macfie Campbell, Dr. W. Permewan, Dr. D. Smart.
Dr. Hugh R. Jones, Secretary.

The sub-committee met three times—on April 22nd and 29th and on May 7th.

Mr. Lowndes submitted a synopsis of the principal recommendations of the Select Committee of the House of Commons, 1894.

RECOMMENDATION 1.—That in no case should a death be registered without production of a certificate of the cause of death, signed by a registered medical practitioner or by a coroner after inquest.

Resolved.—That this recommendation be amended so as to read:

Digitized by Google

That in no case should a death be registered without production of a certificate of the cause of death signed by a registered medical practitioner or by a coroner after inquest or after informal inquiry with medical assistance.

A fee of one guinea was suggested for a medical report and an additional fee of one guinea for a post-mortem examination.

It was thought desirable that the medical practitioner first called should be selected, whenever possible, to make the report.

RECOMMENDATION 2.—That in each sanitary district a registered medical practitioner should be appointed as public medical certifier of the cause of death in cases in which a certificate from a medical practitioner in attendance is not forthcoming.

Resolved.—That this recommendation be rejected.

RECOMMENDATION 3.—That a medical practitioner in attendance should be required, before giving a certificate of death, to inspect personally the body; but if on the ground of distance or for other sufficient reason he be unable to make this inspection himself he should obtain and attach to the certificate of the cause of death a certificate signed by two persons, neighbours of the deceased, verifying the fact of death.

Resolved.—That this recommendation be approved.

RECOMMENDATION 4.—That medical practitioners should be required to send certificates of death to the registrar instead of handing them to the representatives of the deceased.

Resolved.—That this recommendation be rejected.

RECOMMENDATION 5.—That a form of certificate of death should be prescribed, and that, in giving a certificate, medical practitioners should be required to use such form.

Resolved.—That this recommendation be approved.

The following form of death certificate was approved:—

BIRTHS AND DEATHS REGISTRATION ACT, 1874.

MEDICAL CERTIFICATE OF THE CAUSE OF DEATH.

To be given by the Medical attendant to the person whose duty it is to give it with information of the death to the Registrar of the sub-district in which the death took place, and to NO OTHER PERSON.

No. of f. ..... corresponding entry in Register Book of deaths to be inserted here by Registrar.

I HEREBY CERTIFY that I attended ..... at ..... during h..... last illness; that such person's age was stated to be .....; that during that illness I first saw h..... on the ..... day of ....., 18.....; that I last saw h..... alive on the ..... day of ....., 18.....; that ...he died* ..... on the ..... day of ....., 18.....; that I saw and identified the body on the ..... day of ....., 18.....; and that, to the best of my knowledge and belief, the cause of h.....death was as hereunder written—

Cause of death.	Duration of disease in years, months, days, or hours.†
Primary	.....
Secondary	.....

† The duration of each form of disease or symptom is reckoned from its commencement until death occurs.

Witness my hand, this.....day of.....18.....

Signature.....

Registered qualification.....

Residence.....

N.B.—This certificate is intended solely for the use of the Registrar, to whom it should be delivered by the person giving information to him of the particulars required by law to be registered concerning the death. Penalty of £2 for neglect of informant to deliver this certificate to the Registrar.

*** The Registrar-General cautions all persons against accepting or using this certificate for any purpose whatever except that of delivering it to the Registrar.

The medical practitioner in attendance is required, before giving a certificate of death, to inspect, personally, the body; but if on the ground of distance or for other sufficient reason he is unable to make this inspection himself he must obtain and attach to the certificate of the cause of death a certificate signed by two persons, neighbours of the deceased, verifying the fact of death.

* If from any circumstances the death be not verified by the certifying medical practitioner a certificate of verification must be attached. The words, "As I am informed," must be inserted after the words "that he died," and the words "that I saw and identified the body on the ..... day of ....., 18....." must be erased.

THE HOLIDAY SEASON.

THE advent of summer weather brings with it the momentous questions, "Where shall we go?" and "How shall we get there?" For the invalid the first question will, no doubt, be settled by the medical attendant, who is also frequently consulted with regard to the second question. We therefore propose to call attention to the facilities which are afforded by the various railway and steamship companies for reaching popular health resorts and watering places, and to give such information as will enable our readers either to select a suitable place for recouping their own flagging energies after the year's daily round of toil or to give useful advice on the subject to their patients. The rate at which we live in the present day makes it a duty which every one owes to himself to take a rest once a year and, if need be, some sacrifice should be made to procure it. By rest, however, we do not mean inaction, for it must be remembered that physiological rest does not necessarily consist in inactivity. What is required is a change from the work that has occupied the mind or the body during the year. The old lines—

> "Arise betimes, to pump repair,
> First take the water, then the air,
> Most moderate be in meat and drink,
> And rarely, very rarely, think,"—

contain wisdom which might with advantage be applied, not only by visitors to "baths," but by all.

Those who are quite undecided as to the direction in which to travel will do well to seek the advice of the indispensable Cook or Gaze, but having once decided the question of "where" the "how" is a matter that can be readily settled.

THE GREAT EASTERN RAILWAY.—The activity of this company in opening up to holiday seekers such places as the Broads in England, the Ardennes in Belgium, and various parts of Holland and Germany deserves a word of praise, but it is to be regretted that it does not minister to the comfort of its third-class passengers with the same ardour as the Midland and Great Northern Railways. It can hardly be said that the Broads and the Ardennes afford "fresh woods and pastures new," especially since this enterprising company has arranged its annual tours and excursions, but in both places the traveller will experience that rest and novelty which he needs if he will only plan his holiday judiciously. Holland, Germany, Denmark, and Scandinavia fare countries to which the Great Eastern Railway offer special acilities for travellers. Scheveningen, the Dutch Brighton, is most easily reached. At 8 P.M. it is possible to dine in London, and at 8 A.M. the next morning to be breakfasting by the Dutch sea. Combined with mornings in the bright little court capital, The Hague, with trips to Delft, to Haarlem, to Leyden, to Amsterdam, and the other historic, antiquarian, and artistic centres of Holland, the holiday may be made a pleasant and profitable one. The return fares from London to Scheveningen (tickets available for sixty days) are: first class, 50*s.* 4*d.*; second class, 34*s.* 6*d.*; while fares from the north and midlands are equally moderate. The journey home from Scheveningen is made under the same comfortable conditions as the outward trip. The traveller catches the train leaving The Hague at 10.2 in the evening and arrives in London at 8 o'clock next morning, at the north and midland towns in the afternoon. The excursions to Germany *viâ* the Hook of Holland are equally cheap and convenient, and special fares are announced till October to the Berlin Industrial and Budapest Millennial Exhibitions. The possible combinations of tours in Denmark, Norway, and Sweden are only limited by considerations of purse and leisure. For those seeking rest and quiet and fond of yachting and fishing the Land of the Broads is fast becoming a favourite holiday ground. To describe all the tours which may be taken by the aid of the Great Eastern Railway Company in this district would occupy too much space, but two excellent little pamphlets, "Summer Holidays in the Land of the Broads," containing descriptive notes with particulars of facilities for fishing, yachting, holiday parties, &c., and "Holiday Notes in East Anglia," to be obtained at any of the company's offices, will supply the holiday maker with all the information he requires. A pamphlet giving a list of furnished lodgings to be let in farmhouses and country

Digitized by Google

villages in Essex, Hertfordshire, Cambridge, Suffolk, and Norfolk will also be found useful. "Circular Tours by Rail and Saloon Steamboats" will be issued in July next. All these pamphlets are issued gratis. Various tours by this company are advertised from time to time in our columns and further information can be obtained on application to the traffic manager.

THE MIDLAND RAILWAY.—The ramifications of the lines of this company, extending as they do to so many parts of England, make it difficult to locate its boundaries. In a north-westerly direction there are termini at Liverpool and Morecambe, in the north the line extends to Carlisle, and in the north-east to York. The southern extremities of the line are London, and the south of England on the one side, and Bristol, Bournemouth, and the West of England on the other. Swansea, in Wales, and Cambridge, Lynn, Cromer, Yarmouth, and other eastern counties towns are also in touch with this company's iron ways. A glance at the company's map will show that the line runs through the entire length of England from north to south, with connexions from east to west, enabling it to bring within the scope of its carrying arrangements most of the important business centres and health and holiday resorts of Great Britain. For comfort and ease of travelling this company compares very favourably with the other lines, and the introduction of third-class carriages on all trains and the abolition of the second class is noteworthy. The carriages are warmed by steam and on some of the express trains third-class dining carriages are provided. Such luxuries, too, as pillows for night passengers and luncheon baskets are readily obtained. Stop over (or break of journey) privileges are allowed at many points of interest on the journeys, and through tickets are issued to places on other companies' lines. The programmes of tourist ticket arrangements give details of various cheap excursions and tours to and in the principal holiday resorts in the British Isles, including Morecambe and the Lakes, Isle of Man, Ireland, Bournemouth, Isle of Wight, Channel Islands, the Peak of Derbyshire, Norfolk Broads, North Wales, the watering places of Yorkshire and Lancashire, the west and south of England, Scotland, &c. The new edition of the illustrated pocket guide to the Midland Railway, price 6*d*., gives a succinct account of the scenery and places of interest through which this line passes, embellished with charming vignettes, while the Midland Railway holiday tours in the British Isles (price 3*d*.), also illustrated, contains descriptive notes, tourist fares from principal towns, and list of furnished lodgings in farmhouses, country villages, &c., adjacent to the line. The arrangement of this latter publication is excellent, and the guide should be in the hands of everyone who contemplates a journey on the Midland Railway.

THE GREAT NORTHERN RAILWAY.—This is another company which studies greatly the convenience of its passengers, and both first- and third-class dining corridor cars are attached to many of the trains. The Great Northern Railway communicates with Nottingham, Sheffield, Manchester, Liverpool, Leeds, Bradford, Keighley, Halifax, York, Newcastle, Edinburgh, Glasgow, and all parts of Scotland. In connexion with the NORTH-EASTERN RAILWAY this company issue a tourist programme giving details of the East Coast Route to Scotland, with descriptive notes and vignettes of the principal objects of interest by which the line passes. Tourist tickets which offer some advantages will be issued until October 31st and will be available by all trains, except that tourist tickets issued to Scarborough, Whitby, Robin Hood's Bay, Filey, and Bridlington will not be available by the 10 A.M. Scotch express from King's-cross during the time the 10.25 A.M. express is being run. Tourist tickets between Great Northern stations and stations in Scotland, and between Great Northern and other stations in England will, with a few specified exceptions, be available for the return journey without extra payment until Dec. 31st, 1896. Scarborough, Whitby, Filey, Bridlington, Saltburn, Harrogate, Ilkley, Ben Rhydding, Barnard Castle, Whitley, Cullercoats, Hexham, Alnmouth, Alnwick, Berwick, &c., are readily reached by this line, as are also Norwich, Sheringham, Cromer, North Walsham, and Yarmouth. Intending visitors to Scotland will also find some cheap and comprehensive tours by consulting the "Programme." "The Farmhouse, Country, and Seaside Lodgings' and Hotels' Guide" (illustrated), issued by this company, will prove useful. Information as to trains, fares, &c., may be obtained at the booking and other offices of the Great Northern and North-Eastern Railway Companies.

THE LONDON, BRIGHTON, AND SOUTH COAST RAILWAY communicates with such places as Portsmouth, Southsea, Sandown, Shanklin, Ventnor, Worthing, Bognor, Hastings, and Newhaven, and *viâ* Dieppe to Paris, Rouen, Havre, Honfleur, Trouville, Bayeux, Caen, and Cherbourg. The South of France, Italy, and Switzerland are also readily reached by this railway. The tourist and excursion programme gives particulars of a number of excursions and tours on the South Coast, Isle of Wight, Scotland, Ireland, and the Isle of Man, the Lake district, Wales, &c. The Italian tours give a wide range for choice.

THE LONDON AND SOUTH-WESTERN RAILWAY.—The programme of cheap tickets and general excursion arrangements will be found useful to travellers to Guernsey, Jersey, the West of England, and Isle of Wight. The various tours are too numerous to mention individually, but the programme, which contains a list of farmhouses and other apartments to be let in North Cornwall during the summer months, can be obtained on application to the General Manager, Waterloo Station, or at any of the Company's offices.

THE LONDON, CHATHAM, AND DOVER RAILWAY.—The summer service of this company includes cheap week-end and day excursions to the principal seaside and country towns on the line.

In connexion with the "Belle" Steamers, Limited, cheap through tickets are issued to Southend, Clacton-on-Sea, Felixstowe, Harwich, and Ipswich.

(To be continued.)

THE FESTIVAL DINNER IN AID OF THE FUNDS OF GUY'S HOSPITAL: THE PRINCE OF WALES PRESIDES.

THE Prince of WALES presided on Wednesday evening last over a great festival at the Imperial Institute in aid of Guy's Hospital, whose funds, in consequence of the depreciation in the value of land, have sadly fallen away. About 500 guests sat down at the dinner. Among others present, in addition to the staff of the hospital, were: Lord Alington, Sir F. Abel, Dr. Adler, Dr. Clifford Allbutt, Mr. A. J. Balfour, the American Ambassador, Mr. Bonsor, M.P., Mr. T. Bryant, Mr. Henry Burdett, Mr. W. H. Burns, Mr. Burdett-Coutts, M.P., the Earl of Denbigh, Lord Egerton, Lord Elcho, Sir H. Farquhar, M.P., Mr. W. L. T. Foy, the Duke of Fife, Alderman Faudel-Phillips, Mr. H. S. Foster, M.P., Dr. A. D. Fripp, the Rev. the Hon. E. Carr-Glyn, the Earl of Gosford, Sir E. Green, Sir W. C. Gull, M.P., Lord George Hamilton, M.P., Lord Herschell, Mr. H. G. Howse, Mr. S. Hoare, M.P., Sir J. H. Kennaway, M.P., Admiral Sir Henry Keppel, Mr. Letchworth (Grand Secretary of English Freemasons), Mr. E. H. Lushington (treasurer), the Duke of Marlborough, the Rev. H. L. Paget, Lord Penrhyn, Dr. P. H. Pye-Smith, Lord Roberts, the Bishop of Rochester, Lord Rothschild, Mr. J. B. Robinson, Mr. Reuben Sassoon, Sir J. Sebag-Montefiore, Dr. L. E. Shaw (dean), Mr. J. Stern, Mr. Sykes, Mr. Abel Smith, M.P., Sir C. Tennant, Lord Tweedmouth, Cardinal Vaughan, Sir Somers Vine, Dr. Wilks, Lord Wandsworth, Lord Wantage, the Earl of Warwick, the Bishop of Winchester, the Rev. J. E. C. Welldon, and Sir Sydney Webb.

The Prince of WALES proposed the toast of "The Queen," which was drunk with enthusiasm.

Mr. A. J. BALFOUR proposed "The Prince and Princess of Wales and the rest of the Royal Family," which was heartily drunk, and to which the Chairman briefly responded.

The Prince of WALES proposed "The Army, Navy, and Reserve Forces," to which brief response was made by Admiral of the Fleet Sir H. KEPPEL and Field-Marshal Lord ROBERTS, V.C., both of whom testified to the excellent work of the medical men in the services.

The Prince of WALES then proposed the toast of the evening, "Guy's Hospital." He said: We have met here this evening to take steps that the benevolent work of Guy's Hospital may be continued uncontractedly, the long exemption from the necessity for an appeal having made it difficult for the authorities to remove the impression that Guy's is permanently and sufficiently endowed. The founder, Thomas Guy, a bookseller and publisher of London, invested his money for the hospital so that for 150 years the income

Digitized by Google

derived placed the governors in a position to inform intending donors that there were other charities in greater need than Guy's. It was in 1724 that Guy founded the hospital which bears his name. One hundred years later—in 1829—a second merchant and citizen of London, William Hunt, left £180,000 to enable the original foundation to support the increased demands upon it. Guy's building is now used entirely as surgical wards, and the block known as "Hunt's House" is wholly devoted to medical cases. During the next fifty years—1830 to 1880—the hospital was able to maintain its wards, comprising 600 beds, fully equipped and always crowded, but adequately endowed. At last, however—fifteen years ago—there occurred the great fall in the value of land, in which, according to the will of the founder, the entire capital bequeathed had been compulsorily invested. Then, for the first time, the endowment proved insufficient. The governors, hoping the depression was only temporary, closed 100 beds. This decline in the value of land not only continued, but increased, and the governors, brought face to face with the necessity of still further curtailing the scope of the operations of the hospital, or of enlisting public support, appealed for £100,000 to carry them over what they still hoped was only a temporary difficulty. £114,000 was generously given, but has all been expended, for, notwithstanding that 100 beds have been closed, and that no hospital is more economically managed, £40,000 a year is required to maintain this great charity, whereas the endowment now only brings in £20,000 per annum. We must now, unfortunately, recognise the fact that the depression has proved to be not merely temporary, but permanent, and we have met here to-night to decide whether the board of governors, who are again in the same dilemma, can continue to carry on the work of this noble institution with its former thorough efficiency without curtailment of its previous extensive sphere of action. Owing to its position, on the outskirts of a densely-populated and poor district, it has been able to minister to the medical requirements of no fewer than 160,000 needy patients a year. This immense number includes 3,300 maternity cases, which were attended at their own homes, and often provided with the necessities of life, as you will see by the statistics which are in the hands of you all. Every day cases have been turned from the doors and sent on a tedious, sometimes a painful, journey through the London streets to some less crowded hospital. If any of those whom I meet here to-night would go to Guy's—and I speak from personal experience—and see for themselves the overcrowded state of the wards and the disappointed faces of those for whom beds cannot be found, they would, I am sure, agree with me that it would be deplorable were the authorities compelled to close more beds. If we are unable to act on the recommendation of the House of Lords' Commission, and to establish a third great general hospital in South London for the poor, we may, at all events, strive to strengthen the endowment of our forefathers, so that the funds which result from them may not be impaired since we succeeded to the inheritance. To achieve this in the case of Guy's a large sum, it is true, is required; but, when I think of the generosity with which the people of England so often come forward in aid of any really good cause, I cannot but hope that the amount necessary, or at least the greater part of it, will be forthcoming. The sum necessary for this purpose is £15,000 per annum, or half a million of money capitalised. For reasons which I have already indicated, our accounts do not show that we have derived any benefit from legacies; but we hope in the future many benevolent testators will not be forgetful of the merits and needs of Guy's Hospital. I trust, in addition, that through donations to the special endowment fund and through increased annual subscriptions a sufficiently large sum will be forthcoming to render practicable shortly the extensions to the building and further development of the administration. Many who cannot afford a large donation at present in a single sum would perhaps be willing to supplement what they are now able to give by the promise of a larger amount distributed over three or five years; I would ask those who are kindly inclined to inscribe their names as donors to be good enough to intimate to the secretary whether they desire to pay their entire contributions at once or to spread them over a period of say three or four years. I must remind you, in conclusion, that the whole of the money given in response to this appeal will be invested by a strong committee of well-known financiers, and that only the interest derived from the investments will be expended. The money already subscribed, and which is large enough to make this evening for ever memorable in the annals of charity dinners, amounts to £151,000, which, capitalised, would bring in an increased annual income of £5000. The donations are upwards of £100,000, Mr. Gladstone's fund £16,000, and Mr. Incleden has left £35,000.

Mr. E. H. LUSHINGTON, in the absence of Lord Aldenham, replied to the toast.

The Prince of WALES then proposed "Guy's Hospital Medical School" in a few well-chosen words, in which he alluded to its size, efficiency, and complete scientific and recreative equipment and announced that he had accepted the office of President in succession to Lord Aldenham, who had retired through illness.

Dr. WILKS briefly replied, and the company then adjourned to the galleries, where a reception committee, consisting of the Duchess of Marlborough, the Duchess of Portland, the Duchess of Sutherland, the Marchioness of Londonderry, the Countess Cowper, the Countess of Crawford and Balcarres, the Countess Grey, the Countess of Warwick, Lady Aldenham, Lady Randolph Churchill, Lady A. Gordon-Lennox, Lady Esther Smith, Lady Tweedmouth, Mrs. Cosmo Bonsor, Mrs. A. L. Cohen, Mrs. W. Grenfell, Mrs. R. M. Harvey, Mrs. Howse, and Mrs. Pye-Smith, received many friends and supporters of the hospital. The heavy downpour of rain marred the proceedings of the reception and prevented the visitors, who were present in great numbers, from resorting to the gardens.

The total sum given in aid of the Hospital, in response to the Prince of Wales's appeal, including the sums stated in his speech, amounts to £167,528. Included among individual donations are those of the Queen, £105; the Prince of Wales, £105; Mr. A. Beit, £5000; Mr. H. Cosmo Bonsor, £5000; Mr. J. B. Robinson, £5000; Messrs. J. S. Morgan and Co., £5000; Messrs. Barclay, Perkins and Co., £2000; the Earl of Leven and Melville, £1000; Sir Frederick Wigan, £1000; Mr. Fred. Wills, £1000; the Mercers' Company, £1050; the Bank of England, £1000; Messrs. Bass and Co., £1000; Mr. Everard Hambro, £1000; Lord Rothschild, £1000; Butler's Wharf, £1000; Mr. C. Gassiot £1000; Messrs. Barnato Bros., £1000; Mr. W. W. Astor, £1000; Mr. S. Newman, £1000; the Rev. C. H. Wellbeloved, per Mr. H. M. Thornley £1000; White's Club, £1000.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6678 births and 3700 deaths were registered during the week ending June 6th. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 18·5 to 17·6 per 1000, rose again last week to 17·8. In London the rate was 17·3 per 1000, while it averaged 18·1 in the thirty-two provincial towns. The lowest rates in these towns were 11·5 in Croydon, 12·1 in Plymouth, 12·3 in Derby, and 12·7 in Burnley; the highest rates were 21·4 in Oldham, 21·5 in Liverpool, 22·8 in Salford and in Gateshead, 22·3 in Manchester, and 23·8 in Bolton. The 3700 deaths included 559 which were referred to the principal zymotic diseases, against 591 and 540 in the two preceding weeks; of these, 192 resulted from measles, 172 from whooping-cough, 73 from diphtheria, 53 from diarrhœa, 35 from scarlet fever, and 34 from "fever" (principally enteric). The lowest death-rates from these diseases were recorded in Norwich, Derby, Preston, and Newcastle-upon-Tyne; and the highest rates in Wolverhampton, Salford, Birmingham, Manchester, and Gateshead. The greatest mortality from measles occurred in London, Portsmouth, Manchester, Oldham, and Gateshead; from whooping-cough in Cardiff, Wolverhampton, Birmingham, Salford, and Huddersfield; and from "fever" in Gateshead. The mortality from scarlet fever showed no marked excess in any of the large towns. The 73 deaths from diphtheria included 52 in London, 6 in Birmingham, and 3 in Liverpool. No fatal case of small-pox was registered in any of the thirty-three large towns. There were 25 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 6th inst., against 20, 22, and 19 at the end of

Digitized by Google

the three preceding weeks; 8 new cases were admitted during the week, against 6, 5, and 3 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2717, against numbers increasing from 2523 to 2679 on the five preceding Saturdays; 318 new cases were admitted during the week, against 293, 305, and 297 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 217 and 230 in the two preceding weeks, declined again to 213 last week, and were 39 below the corrected average. The causes of 44, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Nottingham, Bradford, Newcastle-upon-Tyne, and in fourteen other smaller towns; the largest proportions of uncertified deaths were registered in Bristol, Birmingham, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·2 per 1000 in each of the two preceding weeks, was again 19·2 during the week ending June 7th, and was 1·4 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14·7 in Leith and 14·9 in Edinburgh to 21·5 in Glasgow and 22·2 in Perth. The 560 deaths in these towns included 26 which were referred to whooping-cough, 25 to measles, 14 to diarrhœa, 8 to scarlet fever, 4 to diphtheria, and 4 to "fever." In all, 81 deaths resulted from these principal zymotic diseases, against 82 and 83 in the two preceding weeks. These 81 deaths were equal to an annual rate of 2·8 per 1000, which was slightly above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had declined from 38 to 27 in the three preceding weeks, were 26 last week, of which 19 occurred in Glasgow and 4 in Paisley. The deaths referred to measles, which had been 21 and 20 in the two preceding weeks, rose again to 25 last week, and included 23 in Glasgow. The 8 fatal cases of scarlet fever showed a further increase upon the numbers recorded in recent weeks, and included 2 in Glasgow and 2 in Aberdeen. The deaths referred to different forms of "fever," which had been 6 and 10 in the two preceeding weeks, declined again to 4 last week, of which 2 occurred in Glasgow. The fatal cases of diphtheria, which had been 3 in each of the two preceding weeks, were 4 last week, and included 2 in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 109 and 97 in the two preceding weeks, further fell to 93 last week, and were 19 below the number in the corresponding period of last year. The causes of 36, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the four preceding weeks from 21·9 to 23·9 per 1000, declined again to 19·8 during the week ending June 6th. During the past ten weeks of the current quarter the death-rate in the city has averaged 23·1 per 1000, the rate during the same period being 18·3 in London and 17·2 in Edinburgh. The 133 deaths registered in Dublin during the week under notice showed a decline of 27 from the number in the preceding week, and included 8 which were referred to the principal zymotic diseases, against 9 in each of the two preceding weeks; of these, 3 resulted from "fever," 2 from scarlet fever, 2 from diarrhœa, 1 from whooping-cough, but not one either from small-pox, measles, or diphtheria. These 8 deaths were equal to an annual rate of 1·2 per 1000, the zymotic death-rate during the same period being 3·4 in London and 0·9 in Edinburgh. The deaths referred to different forms of "fever," which had been 3 and 5 in the two preceding weeks, declined again to 3 last week. The 2 fatal cases of scarlet fever exceeded the number in any recent week, while the mortality from diarrhœa showed a decline. The 133 deaths in Dublin last week included 22 of infants under one year of age, and 34 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the numbers recorded in the preceding week. Five inquest cases and 7 deaths from violence were registered; and 48, or more than a third, of the deaths occurred in public institutions. The causes of 3, or more than 2 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

Surgeon-Colonel Alexander F. Churchill, M.B., to be Surgeon-Major-General, vice J. Jameson, M.D., appointed Director-General, Army Medical Department.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Captain B. G. Seton (Bengal), Officiating Medical Officer of the 18th Bengal Lancers, is appointed to officiate as Medical Officer of the 1st Regiment Central India Horse until further orders. The services of Surgeon-Major A. V. Anderson (Bombay) are placed permanently at the disposal of the Government of Bombay. The services of Surgeon-Captain J. J. Bourke (Bengal) and Surgeon-Lieutenant E. C. Macleod (Bengal) are placed temporarily at the disposal of the Chief Commissioner of Assam. The services of Surgeon-Captain Hudson, Surgeon-Captain J. Garvie, and Surgeon-Captain Lumsden are placed temporarily at the disposal of the Government of the North-West Provinces and Oudh. Surgeon-Major R. R. Whitwell is appointed to be Civil Surgeon of Champaran. Surgeon-Captain C. R. M. Green, who is placed on special duty with Professor Haffkine in connexion with anti-choleraic inoculation, is also appointed to be Civil Surgeon of Bankura. Surgeon-Major J. H. T. Walsh, First Resident Surgeon of the Presidency General Hospital, is appointed to be Civil Surgeon of Rangpur and Gya. Surgeon-Captain H. W. Pilgrim, Second Resident Surgeon of the Presidency General Hospital, is appointed to be First Resident Surgeon of that institution. Surgeon-Captain D. M. Moir, Deputy Sanitary Commissioner, Metropolitan and Eastern Bengal Circle, is appointed to be Second Resident Surgeon of the Presidency General Hospital.

NAVAL MEDICAL SERVICE.

Staff-Surgeon John Lewis Bagnall-Oakeley has been placed on the Retired List.

The following appointments are announced:—Staff-Surgeon S. T. O'Grady to the *Medusa*. Surgeons: George A. S. Bell to the *Vulcan*; William R. M. Young to the *Vernon*; and Thomas C. Meikle, M.B., to the *Nelson*.

VOLUNTEER CORPS.

Artillery: 2nd Glamorganshire: Robert John Richard Cobden Simons, Gent., to be Surgeon-Lieutenant. *Rifle:* 4th Volunteer Battalion the Devonshire Regiment: Surgeon-Lieutenant-Colonel J. Harper resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement. 1st (Hertfordshire) Volunteer Battalion the Bedfordshire Regiment: Surgeon-Lieutenant A. J. Boyd, M.D., to be Surgeon-Captain. 3rd Volunteer Battalion the Welsh Regiment: Surgeon-Lieutenant E. S. Warburton resigns his commission. 1st Bucks: James Shaw, M.D., to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Duke of Edinburgh's (Wiltshire Regiment): Surgeon-Lieutenant-Colonel E. N. Carles resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement.

THE LONDON COMPANIES OF THE VOLUNTEER MEDICAL STAFF CORPS.

The new headquarters of the London companies of the Volunteer Medical Staff Corps were opened on Wednesday, June 10th, and the prizes were distributed by H.R.H. the Princess Louise. Among those present were Surgeon-Major-General Jameson, Director-General of the Army Medical Department; Surgeon-Major-General Taylor, Surgeon-Major-General Inkson, Surgeon-Colonel T. O'Farrell, the principal medical officer of the district; Surgeon-Major Bedford, and Deputy-Surgeon-General Ryeson of the Canadian army. In opening the proceedings Surgeon-Lieutenant-Colonel Norton stated that the corps numbered 484 men, some twenty under the authorised strength, and urged the necessity of keeping the corps up to the full strength in order that the capitation grant might not be curtailed. He also dwelt upon the importance of training volunteer corps in camps with the Regular Army. Referring to the dearth of officers from

Digitized by Google

which this corps suffered in common with other Volunteer corps he called attention to the fact that the Government had made arrangements by which every officer entering from this time would be allowed the sum of £20. This was important because many officers did not join owing to the inconvenience perhaps of expending some £70 for uniform, &c. After the prizes had been distributed the Marquis of Lorne, acknowledging a vote of thanks enthusiastically accorded to her Royal Highness, said the Medical Staff Corps was a branch of the auxiliary forces in which Lord Wolseley, the Commander-in-Chief, took a very great interest. On behalf of the Princess he congratulated the corps on their numbers, zeal, and organisation, and remarked that they set an excellent example to the ladies, who, he suggested, might form organisations for nursing the wounded in cases of urgency.

THE MASIELLO SYSTEM OF FENCING.

The system of fencing lately introduced into the Army has been the subject of some criticism in THE LANCET,[1] and last week Colonel Fox gave a private demonstration of the *rationale* of the new infantry sword exercise before Sir William MacCormac and a number of other medical gentlemen interested in the matter. Of course there are two sides to the question—the practical and the theoretical—but judging from the swordsmanship seen at the Royal Military Tournament this year, both mounted and on foot, which has shown a very marked improvement over that displayed in any previous year, it would seem that there was some practical ground for the official adoption of the Masiello system last year.

THE FRENCH LOSSES IN MADAGASCAR.

According to an official return made by General Billot it appears that the total loss in Madagascar amounted to 5592, that of Europeans being 4189 and of non-Europeans 1403. The military forces lost 2767 in Madagascar, 350 at sea, and 220 in hospital at home, and 80 were missing. The officers who were killed or died amounted to 35.

THE MATABELE RISING.

There has been a good deal of sharp work with the Matabeles in the vicinity of Bulawayo. The wounded in the recent fighting are reported to be doing well.

Correspondence.

"Audi alteram partem."

HOSPITAL SUNDAY.

To the Editors of THE LANCET.

SIRS,—The twenty-fourth anniversary of "Hospital Sunday" in London falls on Sunday next, and as President and Treasurer of the Fund I invite your courteous assistance in giving publicity to the annual appeal which each successive Lord Mayor has felt it his duty to make since the movement was initiated at the Mansion House.

At no period in the history of the Fund were the claims upon it more urgent. Last year the voluntary hospitals and medical charities relieved over 1,463,000 patients at a cost of £718,264. The ordinary income of these institutions only amounted to £576,447, leaving a deficit of £141,817. The receipt of substantial legacies enabled some of the hospitals to balance the year's accounts, but the majority of the institutions remain in debt, anxiety, and difficulty. But the most serious point is that even these results were only attained through a compulsory abandonment, for want of funds, of a large portion of the work of which the hospitals of London are capable. This is seen from the fact that while the number of beds available for the sick and suffering poor is 9005, only 6351 were able to be used last year, leaving no fewer than 2654 empty, solely for lack of the resources necessary to maintain and restore to health the patients for whom they were intended.

This year the Hospital Sunday Fund has applications from 127 hospitals and 54 dispensaries to participate in the collections to be raised on Sunday, and it is estimated that at least £100,000 will be required to meet their pressing needs. The progress of the Fund has been continuous and gratifying. In 1873 the receipts were £27,700. Last year they reached a total of over £60,000, but of this £15,000 was the result of a special collection on the Stock Exchange and a few munificent offerings which this year will be missing. In all, £828,697 has been raised on Hospital Sunday in the past twenty-three years, and the expenses of collection have averaged only 2·6 per cent. The increase in the contributing congregations has been equally striking for these have risen from 1072 in 1873 to 1817 at the present time. A few congregations now omit to take part in the movement. These figures establish that while much has been done in the past, the need of providing for the requirements of the sick poor of London is increasingly and pressingly growing, and that the necessity for enhanced liberality on Hospital Sunday becomes correspondingly great. Any diminution of public sympathy in this movement can only result in a further reduction of hospital usefulness and an addition to the already large number of empty beds and disused wards.

To dwell in detail on the work done in the hospitals would be wearisome, but if the record of patients attended is insufficient to commend them to public support I would allude to those other aspects in which they may be regarded—as the great training schools for medical men and skilled nurses and their use in the discovery and the application of scientific methods for the prevention and treatment of prevalent disease inseparable from a huge city like London, where multitudes of people are forced to live in unhealthy, injurious, and insanitary surroundings.

"Hospital Sunday" has another beneficent feature. It is the only one day in all the year in which people sink their religious differences and combine in a solemn act of devotion and charity in behalf of their sick, suffering, and dying fellow creatures. To coöperate in so beneficent a work is, indeed, a privilege, and I venture to think that "Hospital Sunday" may, under the Divine blessing, not only have the direct result of largely benefiting the hospitals, but produce such feelings of unity and goodwill as cannot fail to have a wide influence in our religious, social, and charitable work.

I have the honour to be, Sirs, your obedient servant,

WALTER WILKIN, Lord Mayor.

P.S.—Contributions of those who may be prevented from sending their donations through a place of worship will be gratefully received by Mr. H. N. Custance, the Secretary of the Fund, at the Mansion-house.

Mansion-house, June 11th, 1896.

EXAMINATION REFORM.

To the Editors of THE LANCET.

SIRS,—Mr. Teale's admirable address and your excellent article in support of it encourage the hope that we may be in sight of some reasonable solution of the examination problem. Up to the present time vested interests have had it all their own way and common sense has been excluded from the discussion. Is it too late to hope that reason may prevail? I have no doubt that the vast majority of the profession or at least of those who have ever given any thought to the subject will agree that there ought to be a simple and uniform system of qualifying examinations in each division of the kingdom, held directly or indirectly under the control of the General Medical Council, which should give the right to registration in the first instance. After being once upon the Register the practitioner could subsequently obtain any special qualifications he desired and these could be added to his registered description. All this might be done by adapting the machinery already established by the Conjoint Boards.

I am, Sirs, yours truly,

Birmingham, June 10th, 1896. ROBERT SAUNDBY.

AUGMENTATION OF THE BLOOD-MASS IN CHRONIC HEART FAILURE.

To the Editors of THE LANCET.

SIRS.—In his masterly lectures on the Causation of Dropsy recently published in THE LANCET[1] Dr. Starling refers to

[1] THE LANCET, Nov. 30th, 1895, March 28th and April 11th, 1896.

[1] THE LANCET, May 9th, 16th, and 23rd, 1896.

Digitized by Google

the tendency of the blood-mass to increase in cases of chronic heart failure. After pointing out that the primary effect of cardiac failure is to lower capillary pressure he insists on the clinical fact that there is often evidence of high capillary pressure in uncompensated heart disease. How are these facts to be reconciled? "The clue to this difficulty is," he believes, "to be found in the fact that all cases of uncompensated cardiac lesions are associated with hydræmic plethora. This association has been shown actually to exist by the observations of Stintzing and Gumprecht. I wish, however, to show you," continues Dr. Starling, "that such a condition of hydræmic plethora must be an inevitable physiological consequence of the failure of the heart pump. We have just seen that heart failure causes a fall of ..... capillary pressure. This fall, like that consequent on artificial anæmia, will disturb the relationship between the blood and the lymph; there will be an absorption of lymph from the tissue spaces—the blood will be increased in volume." I had myself already come to the conclusion that the blood-mass tends to be augmented in chronic heart failure, and as this is a point of considerable practical interest to the physician I may perhaps be permitted to quote from an unpublished manuscript (written some two years since) in which my reasons for this conclusion are set forth. "In many cases of passive congestion of the lungs and systemic veins, or of the latter alone, the volume of blood is, I believe, increased. It is evident that an accumulation of blood in these parts must, unless the blood-mass be augmented, lead to a depletion of the systemic arteries and a defective supply to the capillaries, causing a fall of capillary blood pressure. So far as these latter vessels are concerned, the effect of transferring for any length of time a portion of blood which should be in the arteries to the veins is much the same as removing that amount of blood from the body. In each case the essential result is a diminution in the quantity of blood passing through the capillaries, the diminution being actually greater in passive venous engorgement than from bleeding owing to the circulatory defect accompanying the former condition. Now, after bleeding the blood tends to regain its wonted quantity and quality, the organism appreciating the loss by reason, we may suppose, of the capillary dearth of blood, and one would expect the same kind of thing to happen when the individual bleeds into his systemic veins and pulmonary vessels. This conclusion is supported by clinical observation. While passive venous engorgement is often accompanied by emptiness of the systemic arteries, as shown by the smallness of the radial pulse, this is by no means always the case. Sometimes the radial artery is quite large and there is every evidence of arterial plethora, which would be impossible were there no increase in the total volume of blood. Again, in marked venous engorgement there would sometimes appear to be high capillary pressure, as shown by a florid complexion and a copious urinary flow, and it would be impossible to get this were the arteries defectively supplied with blood, as would happen if its mass were not augmented." It will be observed from this passage that I go even further than Dr. Starling, holding, as I do, that the increase in the blood referred to is not merely a watery increase, but that the solid constituents of the blood are at the same time augmented, though doubtless hydræmia is often observed.

The degree of augmentation of the blood mass consequent upon heart failure differs greatly in different cases. I have now under observation two patients presenting extremes in this respect. The one has great distension of the superficial vessels of the face; his radial artery is large and tense, and if he allows his hand to hang down by the side of the bed it rapidly becomes œdematous. In this case capillary pressure is high and the volume of blood must be considerably augmented. The other patient, who has an enormously dilated heart, is anæmic in appearance; his radial pulse is very small and scarcely perceptible, only one out of every three heart beats being felt at the wrist. It is clear that in this case capillary pressure is low, and it is probable that the blood-mass is not greatly augmented. I may observe that the tendency to dropsy in this patient is less than in the other, and this bears out Sir William Broadbent's suggestion that cardiac dropsy is more apt to occur when arterial tension is well maintained than when it is very low, a conclusion, by the way, in entire keeping with Dr. Starling's teachings as to the causation of cardiac dropsy.

I am, Sirs, yours truly,

Devonshire-street, W. HARRY CAMPBELL.

"THE PREVALENCE OF DIPHTHERIA IN CONNEXION WITH ELEMENTARY SCHOOLS."

To the Editors of THE LANCET.

SIRS,—I shall be obliged if you will grant me space to make a few comments upon the article which appeared in THE LANCET of May 23rd relative to a report which I have recently presented to the School Board for London in response to the following resolution: "That the medical officer be requested to report generally on the prevalence of diphtheria in London and elsewhere, and its alleged connexion with the elementary schools, and, further, to advise what, if any, steps the Board should take in the matter."

You are in error in implying that this resolution was arrived at consequent upon the publication of any memorandum by Mr. Shirley Murphy. The notice of the Board had on several occasions been drawn to the increasing prevalence of diphtheria in London and the opinion which had been expressed by various writers, amongst them Mr. Shirley Murphy, of the possible agency of the schools in spreading the disease; and for these reasons the above resolution was passed. In the course of my report I had occasion to refer to the observations of certain writers, and in this way to those of Mr. Shirley Murphy; but in your article the whole question is made apparently to revolve round the personality of that gentleman. I note that you think Part I. of the report, which deals with the geographical distribution of the disease since 1861, although "interesting," is not "relevant" to the question. But why? Elementary schools are found all over the country; diphtheria is not, scarlet fever is not, and measles is not; doubtless all these diseases are sometimes communicated in schools, as they are sometimes in churches, children's parties, &c. But if schools are the main cause or even a principal cause of the diffusion of infectious diseases, why, may I ask, do the schools select diphtheria in Sussex and measles in Staffordshire? Should not the words "not ..... relevant" contained in your article be read "not convenient"? for questions like these would appear very important to the enquiry, "How much do elementary schools have to do with the selection and diffusion of the different zymotics that prevail in different localities"? and they point to the fallacy of assuming that when the schools have been denounced the last word has been said. The comparison which I made between 1881–90 and 1871–80 is a perfectly right one. The question for me to consider was, When diphtheria increased in 1881–90 how did it affect different ages? Other factors beside school attendance would have been present in making a comparison with a more distant period, the character of the disease might have changed, certainly the conditions of housing had altered, &c.

I see that a somewhat adroit manipulation of figures is suggested by the writer of the article to enable him to escape from the difficulty in which he finds himself. I have constructed, however, the following table:—

—	Death-rate 3–10 (all ages 100).	Percentage attending Elementary Schools.	Percentage addition.	
1871–75...	324	31·6	5·9	39·2
1876–80...	343	44·0	2·7	15·7
1881–85...	352	50·9	1·1	9·2
1886–90...	356	55·6	1·1	5·0
1891–94...	360	58·4		
Totals	—	—	11·1	81·6

From this it will be seen that in 1891–94, as compared with 1871–75, there is an addition of 81·6 per cent. to the number of children attending school, and at the same time there was an addition of 11·1 to the diphtheria rate compared with that at all ages. I have admitted that children do sometimes contract diphtheria at schools, and apparently the effect of nearly doubling the school attendance is to add 11 per cent. to the risk of diphtheria calculated in this way. I regret that something like a sneer is sought to be conveyed in your criticism of my use of the Asylums Board nurses and teachers of the School Board. It would appear impossible to carry out an inquiry into school influence without the aid of the latter, and I

Digitized by Google

venture to think the services of the nurses were also of a most valuable kind; at any rate, comfort is sought for Mr. Murphy in the result of the investigation, which shows only 7·6 per cent. of the cases to be possibly attributable to school influence, "a complete justification of the position which he has assumed" being found therein. One is tempted to ask, what about the origin of the remaining trifle of 92·4 per cent. of the cases? That the schools are not to blame for the great increase of diphtheria in London I am convinced, and the sooner we abandon this unstable view and set to work to find out the real cause the better for science and the better for the metropolis.

I am, Sirs, yours faithfully,

June 8th, 1896. WILLIAM R. SMITH, M.D. Aberd.

*** The space at our disposal does not permit us to do more than comment briefly on the matter referred to in Dr. Smith's letter. We must be pardoned if we have assumed that his report is intended as a reply to the reports of Mr. Shirley Murphy, seeing that of the pages in Dr. Smith's report which we can regard as relevant to the subject of the influence of schools on diphtheria prevalence at least three-quarters are devoted to a criticism of Mr. Murphy's two points—(1) the change in the age incidence of diphtheria mortality since 1870; and (2) the reduction in the number of notified cases of diphtheria at the time the London board schools are closed for the summer holidays. Dr. Smith's remarks concerning the comparisons of the decades 1871–80 and 1881–90 make it evident that he still fails to see that a change effected in the main in the decade 1871–80, and conspicuous when comparison is made between 1861–70 and 1871–80, need not (to meet the school hypothesis) be again conspicuous between 1871–80 and 1881–90. We pass by Dr. Smith's incomprehensible reference to a "somewhat adroit manipulation of figures" by the writer of our article "to enable him to escape from the difficulty in which he finds himself." The table in Dr. Smith's letter leads us to the conclusion that he is now prepared to abandon the position he assumed in his report when he wrote "that while the percentage of children attending elementary schools has largely increased—viz., from 24·8 per cent. in 1871 to 59·8 per cent. in 1893—the comparative death-rate at ages three to ten has remained throughout these years fairly constant." As Dr. Smith now evidently sees, it has done nothing of the sort; but, as we pointed out in our article, "with increase of school attendances there has been a gradual increase of comparative diphtheria mortality at the school ages." In studying these figures there is, however, another consideration which must be held in view, and that is that the diphtheria rate at 3—10 *compared with all ages* does not make evident the whole story of the increased incidence of the diphtheria rate on that age. The result is masked and greatly minimised by the fact that the deaths from 3—10 constitute a very large proportion of the deaths at all ages. The comparison, therefore, between the increase of 11·1 per cent. in the comparative death-rate and the increase of 81·6 per cent. in the proportion of the children attending school is absurd. How much of the increase in the death-rate at all ages is due to increased school attendance still remains unknown, and certainly we are not prepared to accept Dr. Smith's 7·6 per cent. of the cases at school age as including anything like all which are "possibly attributable to school influence." Dr. Smith concludes his letter by stating that "schools are not to blame for the great increase of diphtheria in London." We challenge him to refer us to the statement of any person who has said they are. There is a wide difference between the position which regards schools as contributing in important degree to this increase and that which regards schools as the sole factor in such increase. All the evidence at present available points to the inaccuracy of Dr. Smith's conclusion that school influence "plays but an unimportant part" in the increase.—ED. L.

THE CASE OF MR. LIONEL SMITH.

To the Editors of THE LANCET.

SIRS,—Will you allow me through your columns to thank those gentlemen who so kindly came forward to assist me out of the difficulties in which I was placed by the action of the West Australian Government? I have now reached my new home and I hope to make a fresh and successful start in life which, but for the generous aid accorded me, I should have been unable to accomplish.

I am, Sirs, yours faithfully,

H. LIONEL SMITH.

N'Qutu, Zululand, South Africa, May 11th, 1896.

ISOLATION AND THE PUBLIC HEALTH ACT.

To the Editors of THE LANCET.

SIRS,—The following matter, which I will put as briefly as possible, may be of interest and use, perhaps, to some of your readers. Since the introduction of "notification" by the Public Health Act (London), 1891, I have had some trouble with the sanitary authority of this parish of St. George, Hanover-square. During this period it has been the custom to remove as many as possible of the cases of scarlet fever and diphtheria to the Metropolitan Asylums Board Hospitals. Certain cases, however, which I have met with in my practice I have decided, for reasons stated below, to retain and attend at their own homes, and have expressed to the patients' relatives my approval that they should so remain, provided that my directions as to isolation and treatment were faithfully carried out, and therefore they could remain. Notwithstanding this, and knowing that I had expressed this opinion, the sanitary inspector has stepped in, has insisted on the patients being removed to the hospital, and they have been so removed, the grounds given for this action being that the patients were not properly isolated in his opinion.

The cases in question were mostly scarlet fever or diphtheria, occurring in families occupying generally three or four, sometimes only two, rooms; but in each case the patient was put into a separate room from the rest and confined there without any direct communication with other members of the family, the only person going backwards and forwards at all from the sick room being the nurse—usually, of course, the child's mother—whom I made take sufficient precautions against spreading the disease. I have attended many such cases in pre-notification years and have never known the disease to spread after such isolation has been established in any case. Now the question of what is proper isolation is, I maintain, essentially a medical question, and it is intolerable that an unqualified person, such as a sanitary inspector, should be allowed to override the opinion of a medical man on a medical question or to interfere with his patients, nor is it professionally correct for a medical officer of health to disregard the opinion of another medical man. I complained more than once to the medical officer of health (Dr. Corfield), but he supported the sanitary inspector and the offence was repeated. The Public Health Act is not very definite on the matter; but as it declares that any legally qualified medical practitioner may certify that an infectious patient has *not* proper accommodation one would suppose (and this seems to agree with common sense) that he would be equally able and entitled to certify the obverse—viz., that an infectious patient was properly accommodated and isolated. I therefore wrote to the Local Government Board last February, stating the case and giving particulars, and asked for an authoritative opinion. The Local Government Board corresponded with the sanitary authority of St. George's, Hanover-square, and replied to me on the 2nd inst., enclosing a copy of the Board's final reply to the Vestry, as follows:—

Local Government Board, Whitehall, S.W., March 28th, 1896.
To the Clerk of the Vestry, St. George's, Hanover-square.

SIR,—I am directed by the Local Government Board to acknowledge the receipt of your letter of the 18th inst. enclosing a copy of a report which the Vestry of the Parish of St. George, Hanover-square, have received from their medical officer of health respecting the complaint of Dr. Benham, and in reply I am to state that whilst the Board concur with the view expressed by the medical officer of health as to the desirability of securing isolation in hospital of such cases of the infectious fevers as are referred to in his report, they are of opinion that where a medical practitioner is known to be in attendance on any such case, removal to hospital by the officers of the sanitary authority

Digitized by Google

should not be effected without some communication either at the time or immediately after the removal, with the medical practitioner in question.

I am, Sir, your obedient servant,
A. D. ADRIAN, Assistant Secretary.

I hope that there will now be no further friction over this subject. The principal reasons I have had for retaining such patients at home are these:—1. The parents of the child often wish it. 2. It is part of the duty of a medical man to attend such cases. 3. It is very unjust, although it may be legal, for the ratepayers to bear the entire cost of maintenance and treatment, even though the relatives could afford to pay. 4. Patients are longer in recovering if treated at the hospitals—at any rate, they are always detained there, I believe, for ten weeks at least, whereas they can be got well almost always in about six weeks if treated at home. 5. I believe, though it would be difficult to demonstrate it, that cases of scarlet fever have a better chance of recovery and avoiding complications—e.g., diphtheritic sore-throat at a late stage—if treated at home. 6. It is a very easy matter to isolate cases of scarlet fever and diphtheria. By strictly observing a few simple precautions there is scarcely any risk, according to my experience, of the infection spreading. Surely as a matter of fact most cases of scarlet fever arise from infection by slight and unnoticed cases and most of the rest from imperfect disinfection of clothes, furniture, &c.

I think that it has yet to be proved that the adoption of notification and the removal of every detected case to a fever hospital have any material effect in lessening the prevalence and spread of scarlet fever in London, and what chance is there of stamping the disease out? The question is one of interest and importance, especially considering the enormous cost of the Metropolitan Asylums Board hospitals and the extravagant rise of the rates which the over-burdened ratepayers have to pay. And yet some enthusiasts are beginning to talk of removing cases of measles to fever hospitals. What next?

I am, Sirs, yours faithfully,
F. LUCAS BENHAM, M.D. Lond.

Elizabeth-street, Eaton-square, S.W., June 8th, 1896.

"THE REGISTRATION OF MIDWIVES."

To the Editors of THE LANCET.

SIRS,—I willingly accept Mr. Humphreys' corrections, although I would have imagined that the term "Midwives Institute and its Supporters" as employed by me was sufficiently comprehensive to have included the Midwives Bill Committee. The Local Government Board will perhaps be able to find time for drawing up a code of instructions for the guidance of midwives, as the sanitary portion of these should be an easy day's work for a specialist in that department of knowledge, and the post-office provides a very simple and expeditious means of communication with the local medical officers of health. I am pleased to learn that the Privy Council imported itself into the administration of the Midwives Registration Bill and so provided a good example of unconscious humour, although I would regret to be placed under the necessity of believing Mr. Humphreys capable of anything of that kind. "The rights of existing midwives" do, however, seem to me a rather uncertain quantity, and I am afraid that the legal formulation of these would more than exhaust the resources of even a Philadelphia lawyer, had he the courage to make the attempt. If progress is the development of order it is perhaps desirable that the profession should try to create a little order in the matter now under consideration.

I am, Sirs, yours faithfully,
Salford, June 6th, 1896. WILLIAM FRASER.

"THE CHILDREN OF THE STATE."

To the Editors of THE LANCET.

SIRS,—The report of the Departmental Committee on Poor-law schools having received notice in THE LANCET, allow me to draw attention to certain statements and recommendations in that report which bear my name in the margin, but which are not in accord with my evidence thus referred to and which I cannot approve. In 1890-91 I examined individually 9831 children in Poor-law district and separate schools for a joint committee of the Charity Organisation Society and the British Medical Association, who presented a report embodying those observations to the President of the Local Government Board at his request in June, 1892. At the request of the Departmental Committee I gave evidence from published records as to the children I had seen. This showed that 15·0 per cent. of the boys and 12·2 per cent. of the girls presented some degree of congenital developmental defect predisposing them to low health with mental dulness. In the departmental report conditions found among the children are mainly ascribed to their environment in aggregation, sanitation, and education. Evidence showed that great care in selecting children for boarding-out was necessary; only perfectly normal children should be placed in the less protected position. This would necessarily leave all the cases of developmental defect in the schools. With regard to the "feeble-minded children" I was asked my experience of the best methods of training, and in reply referred to patients who paid £100 to £150 a year for living and training in private families. This evidence is referred to as a ground for recommending that pauper children feeble minded should be boarded out—a proceeding that, in my opinion, would be unwise and unfair to the child. Under the heading "Feeble-minded Children Attending Public Elementary Schools" the committee say: "322. When boarded out or placed in small homes the children attend public elementary schools"; my name is again given in the margin, but does not refer to evidence in support of the statement; I am not aware that feeble-minded children have been boarded out. A statement in the form of a question was made by a member of the committee as to the number of children who required special training at the Mile-end Schools; I did not agree with that statement; the question in place of my reply is inserted in a paragraph of the report. Other points might be mentioned to which exception may be taken; but enough has been said to show that before accepting the conclusions of the report the scientific and medical evidence needs to be compared with the statements and recommendations made.

I am, Sirs, yours faithfully,
Kensington, W., June 6th, 1896. FRANCIS WARNER.

THE FREE HOME FOR THE DYING: THE NELSON BED.

To the Editors of THE LANCET.

SIRS,—We ask those who take an interest in the seafaring class to lend us a hand in keeping up this bed in the Free Home for the Dying. There being no paid staff at the Home all donations are for the benefit of the inmates. Last year kind friends contributed £78 15*s.*, and we now ask for five shillings from all who can afford it, which will provide for the wants of this real charity for this year. Postal orders may be sent to the honorary secretary, at the office, 281, Strand, W.C., or to the bankers, Messrs. Hoare and Co., 37, Fleet-street, E.C.

We are, Sirs, yours faithfully,
W. PORTLOCK-DADSON, Captain, Honorary Secretary.
WILLIAM HOARE, Honorary Treasurer.

June 18th, 1896.

"INDURATED PSEUDO-CHANCRES."

To the Editors of THE LANCET.

SIRS,—Conclusions Nos. 4 and 5 in Mr. A. Shillitoe's paper I thoroughly agree with if the expression "spontaneously" be omitted. The experience of one case in private practice and a few in prison work has taught me that a sore may appear on the place where a chancre has been due to the irritation of masturbation; and, further, that this sore may have a for-all-the-world resemblance to a fresh chancre, and yet that it will not be followed by true secondary symptoms.—I am, Sirs, yours faithfully,

Canterbury, May 30th, 1896. PUGIN THORNTON.

"A DECEPTIVE ETHER INHALER."

To the Editors of THE LANCET.

SIRS,—We notice in THE LANCET of June 6th a letter from Messrs. Mayer and Meltzer disclaiming any connexion with a Clover's inhaler with transposed viscera, mentioned by Mr. M. S. Paul of Nagasaki, Japan, as having come under his notice. As we are just now advertising a Clover's ether inhaler we should be glad if you would insert this letter to the effect that the inhaler mentioned by Mr. Paul is not one of our making, as your readers might think from Messrs. Mayer and Meltzer's letter, which says nothing about it being

Digitized by Google

made in London or that it was one made by us. We beg to say that all of our Clover's inhalers are made on perfectly correct lines and are guaranteed by us.

We are, Sirs, yours faithfully,

PHILIP HARRIS AND CO., LTD.

Birmingham, June 5th, 1896.

THE BATTLE OF THE CLUBS.—XXXII.[1]

(Continued from p. 1527.)

THE BITTER CRY OF THE MEDICAL AID ASSOCIATIONS.

WE cannot pretend to feel sorry for the well-to-do whose little arrangements for being attended by the association medical men at 3*s.* 6*d.* a year have been much upset of late. We are happy to find that *bonâ-fide* members of friendly societies are recognising that the medical profession has its rights and even its duties of combination to insist that the terms of accommodation proper to men of small means shall not be claimed by men who can afford to pay the proper and ordinary fees for medical attendance. At the meeting of the Annual Movable Committee of the Manchester Unity of Oddfellows, held at the Colston Hall, Bristol, on May 28th, on a discussion of a Bill for consolidating the various Friendly Society Acts, Mr. Keyworth of Lincoln (so the *Daily Chronicle* of May 29th reported) introduced the question of the strained relations existing between the medical profession and the medical aid associations in different parts of the country, and proposed "that the Parliamentary agent be instructed to use his best endeavours to obtain a clause in the Friendly Societies Act enabling medical men to take positions as doctors to medical aid associations without let or hindrance." He said that they had suffered very much in Lincoln from the agitation among the medical profession not to accept service under medical aid associations. The proposal was seconded by Mr. Evans of Kidderminster, who actually reported that the profession there had gone so far as to ask their officers to resign their position. Some complained that the profession was proposing to deny the benefits of such associations to those whose wages exceeded 30*s.* or 40*s.* a week or rented a house of £20 a year. Many respected private patients of medical men are to be found with such limited means, the practitioner being quite capable of adapting his charges to their need. But withal the common sense of the British workman, who knows what his class have gained by combination, found expression, and very clear expression too, and in the end the proposal was rejected by a majority of 235 against 195. Our correspondent whose letter follows is not a person with common sense. We are happy, however, to print his letter, that any "medical servants" who read it may recognise in their medical ruler a wise and far-seeing person—if they can.

LETTER FROM A MEMBER OF THE MANCHESTER EXECUTIVE.

To the Editors of THE LANCET.

SIRS,—I presume your columns are open to the criticism by a layman of the attitude you are adopting towards friendly societies, medical institutions, and towards clubs in general. The hostile feeling on the part of the profession will make no difference to clubs whatever, it will end as it did in Lincoln—viz., defeat, ignominious defeat. The unity amongst the flower of the industrial class is too strong for the profession. The latter should understand that it was decreed at Bristol by the delegates representing three-quarters of a million of the Manchester Order "that if in any town the conduct of our medical employés is unsatisfactory, or if they demand a higher rate of payment the lodges should join in the formation of a friendly societies institution worked by one or two medical officers under the superintendence of the committee." The profession will well understand what this means. Recent events do not speak much for the business attitude of the medical profession—a friendly hint, Sirs, when I tell you that the profession will have to be officered by men of tact, experience, and business ability—i.e., a little less of the professional air about them if they intend to cope with friendly societies officials. While the latter are disposed to treat magnanimously their medical officers, as it is to the interests of the lodges that their medical servants should work in perfect harmony with them, the lodges will strenuously resist that spirit of interference which medical journals have encouraged of late. The people of England are not slow in the reception of new ideas as shown by the fact that the Manchester Order is increasing at the rate of 1000 a month in spite of secessions, and women are now swelling the ranks of Oddfellows, so that our future is indeed a glorious one. The Friendly Societies Act was altered early this year, allowing medical institutions managed by us to extend our work to all trades unions and to admit children from two years upwards. This coöperation may be a deadly danger to your profession, but it is indisputably a great blessing to the country. It is predicted that medical attendance for the working classes will be under the direct control of the friendly societies within five years and that the labour distributed amongst some thousands on the Medical Register will fall into the hands of a few hundreds willing to coöperate with the friendly societies officials, from whom every consideration can and will be given. We also propose to engage medical women for large associations where the number of female clubs will justify it. We have now 740 medical men on our Friendly Societies Register, many of these being only too anxious for a job.

I am, Sirs, your obedient servant,

A MEMBER OF THE MANCHESTER EXECUTIVE.

Derbyshire.

LINCOLN: THE PROVIDENT MEDICAL ASSOCIATION.

We have received a copy of the rules and constitution of the newly formed Lincoln Provident Medical Association. We have not space this week to quote the document in full, but the following extract from the rules shows the scale of payment adopted:—

"Families: 1*d.* per week for every several adult, i.e., over sixteen, and 1*d.* per week for each child. In cases where the combined wages of the parents are above 25*s.* a week the total payments shall not be more than 5*d.* per week. When the wages are under 25*s.* a week the total payments shall not exceed 3*d.* a week.

"Single persons: Wages above 25*s.* a week shall pay 2*d.* per week. Wages below 25*s.* a week shall pay 1½*d.* per week.

"Confinements: 15*s.* or 10*s.* 6*d.*, according to whether the wages are above or below 25*s.* a week."

We look upon this as an earnest and honest attempt to get over the differences which have arisen between the friendly societies and their former medical officers. Those unable to pay the full fees are thus given an opportunity of getting medical advice at a price proportionate to their means, while the medical officers, being answerable to no one but their fellow practitioners in the town, will feel in a much more free and dignified position than if they were in the hands of a committee of laymen.

LINCOLN MEDICAL PROTECTION FUND.

The following subscriptions have already been received, and the ready response does credit to the profession. To

FIFESHIRE MEDICAL ASSOCIATION AND MEDICAL AID APPOINTMENTS.

At the last meeting of this association, held at the Royal Hotel, St. Andrews, on June 8th, Dr. W. Stuart Palm, president, Dr. J. Sutherland Mackay moved a resolution: "That the holding of a 'medical aid' society's appointment shall render the holder ineligible for membership in this association." This was seconded by Dr. Curror and unanimously agreed to. The correspondence between the association and Dr. Bruce of Dingwall was then read, and discussion ensued upon the whole question, in which Dr. Nasmyth, Mr. Berwick, Mr. Graham, Dr. Petrie, and Dr. Douglas took part, and the council was instructed that any member holding such appointment should be requested either to resign it or his membership. After the meeting a notice of motion was handed in by Dr. Hamilton Kyle, who was unavoidab'y prevented from being present at the meeting: "That a committee be appointed to inquire and report as to the conditions upon which members of the association may hold friendly or other society appointments, to formulate a code of ethics for the guidance of its members, and to define the powers and duties of an ethical committee."

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday.

HOSPITAL Saturday in Birmingham has always been a popular occasion. It is essentially a working-class movement and has been always conducted with much enthusiasm and vigour. Last year the amount realised was £13,057; this year an appeal for a larger sum was made, not only for the distribution among the medical charities of the town, but for the maintenance of the convalescent homes in Wales. These separate institutions for men, for women, and now, thanks to a liberal anonymous donor, for children also, have been ever regarded with high favour; they have been productive of an untold amount of benefit and happiness. With the same untiring energy and zeal which have characterised the many workers on former occasions the amount this year has reached the sum of £13,777. More will yet come in, and the committee's sanguine expectation of £14,000 will evidently not be very much out of reckoning.

The New Sanatorium.

A valuable addition to the existing benevolent institutions of the town was formally opened at Sutton Coldfield by the Lord Mayor on the 4th inst. This institution is the gift of Lieutenant-Colonel J. H. Wilkinson. The site is a splendid one, the building, formerly an hotel, being well adapted and fitted for the purpose. It is intended more particularly for clerks, warehousemen, assistant school teachers, shop assistants, and small tradespeople—those of a class often poorly paid, whose breakdown in health means stoppage of supplies and great inconvenience and frequently privation. A large audience witnessed the opening and cheered the various proceedings. Donations amounting to £2000 have been promised as well as annual subscriptions of £500. The institution is thus favourably floated. It is entitled to confidence and success for the future.

Singular Death: Heavy Insurance.

A case involved in exceptional and even extraordinary circumstances is now occupying the attention of the police authorities at Acock's Green. A servant girl aged twenty-nine years had been in the service of a family for a little over twelve months. She had been subject to attacks of hysteria and had been warned by the medical man against drinking brandy to what was obviously a detrimental degree. At 7.30 on June 3rd she was apparently in normal health, at 11.30 the same night the medical man received a note to say that she was dead. He wrote to the coroner stating the fact and also that as he had not attended her lately he should recommend an inquest to be held. An inquest was accordingly held, a post-mortem examination made, and evidence of acute inflammation of the stomach of long standing was found. In the medical man's opinion she died from syncope the result of continued sickness, due to the state of her liver and stomach, brought about by the undue use of stimulants. It seems that the girl was examined for insurance on May 6th and passed as quite sound. Now a claim for £8000 has been made by the people with whom she lived, in whose favour she made a will. The body has been again opened and the contents of certain parts placed in the hands of the county analyst.

Medical Benevolent Society.

At the annual meeting, held on May 29th, the directors reported that the invested funds now amounted to £12,109; sixteen annuitants were upon the books, and the annual grants ranged from £15 to £40. The society was stated to be in a flourishing condition.

June 8th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Deadlock at the Lying-in Hospital.

THE offer made by the board of management to submit the questions of difference between them and the late staff to the arbitration of the Lord Mayor has been declined both by the staff and by the council of the Medical Institution as representing the profession. The reasons assigned by the latter for declining the intervention of Lord Derby are as follows: That "the existing difference involves a question of principle in regard to which the medical profession are wholly unable to modify their view. They will, as has been so often stated, with readiness give their services to the charity on condition that their position and responsibilities are those accorded in other hospitals to honorary medical officers. That is to say, they shall have sole and entire professional charge of the patients and a proper representation on the board of management. Upon these points no compromise is permissible. If the board has not sufficient confidence in the honour and discretion of its medical officers to place in their hands the full charge of the patients, and, while withholding it from them, places that charge in the hands of the matron-midwife, the profession, once for all, decline to have any share in a system so unprecedented, so unsatisfactory in the interests of the patients, so dishonourable to themselves, and so subversive of all progress in medical science." They suggest that a special meeting of the subscribers be summoned under the presidency of the Lord Mayor at which both representatives of the profession and of the late staff be present,

Digitized by Google

in order that the whole subject may be dispassionately and impartially considered. The late staff, in also declining arbitration, give their reasons in more forcible language, which reads thus:—"After the resolution passed by your board on May 19th, accusing the medical profession of wanton cruelty and of being utterly regardless of common humanity; and, further, as it is questionable whether your board longer represents the wishes of the majority of the subscribers to the charity, we feel that further communication with your board is attended with difficulty. Moreover, there is no room for arbitration. We have repeatedly laid before you our request for complete authority in our own department, and for representation on the board of management, which we have formulated in these words: (1) that the medical officer on duty at the hospital shall have sole and entire medical charge of all patients in the hospital; and (2) that the medical staff shall be represented on the board of management by four members of the medical board to be selected from time to time by the staff. We consider that at this stage the only possible appeal must be to the subscribers who maintain the charity and are responsible for its future. If they grant our request we shall be happy again to give those gratuitous services which we have given in the past; if they refuse things must remain in their present unhappy position." They proceed by saying that when the meeting of subscribers takes place they hope that the Lord Mayor may take the chair, as they feel confident that under his presidency opportunity will be afforded to explain their position which was denied to their chairman and secretary at the last meeting. They conclude by pointedly drawing the attention of the board of management to the fact that the question of utilising the opportunities of the hospital in assisting students of medicine in their education forms no part of the present dispute. They strongly deprecate the fact that the board should have made use of this question as a side-issue to divert the attention of the subscribers from the real question between them. There can be no doubt from remarks of individual members of the board made in conversation with friends, and from the report of the proceedings of the ladies' committee which have just come to light, that a revolt has taken place in the citadel of management which will probably lead to the retirement of the president from office. The daily papers of June 6th have published, at the request of the ladies' committee, a copy of three resolutions carried at their meeting on May 22nd, and which are as follow: "1. In view of the position taken by the medical profession, the ladies' committee of the Lying-in Hospital desire to record their opinion that the medical officer at the hospital should have sole and entire medical charge of all patients in the hospital. 2. That the medical board be represented on the board of management by two members of the medical staff having a right to vote. 3. That the matron-midwife should stand in the position of house surgeon under the honorary medical officer on the rota." It is satisfactory to find one section of the managing body acknowledging its mistakes by offering the olive-branch, and it will not cause much surprise to find the board of management climbing down from their position of *non possumus* now that it has been so forcibly demonstrated to them that the solid phalanx of a determined unity of action hitherto unparalleled on a similar scale leaves them without hope of conducting their charity on such discredited lines. The contest waged is looked upon as one of principle by the profession, and should serve as a warning to the managers of kindred institutions not to put too great a strain on the susceptibilities of an unpaid staff.

New Ambulance for the Northern Hospital.

Mr. Louis S. Cohen has generously presented this hospital with a new ambulance carriage fully equipped. It is a fine specimen of mechanical skill, and is supplied with everything requisite in the way of surgical appliances and dressing. It affords accommodation for three patients in the recumbent posture, and will carry two or three more in cases of need besides the surgeon and driver. The springs under the body of the ambulance are so contrived as to reduce the vibration to a minimum. The carriage is built of ash and weighs 15 cwt., and by means of an ingenious arrangement the entire harness can be instantaneously removed or applied as the case may be, and a start made within half a minute of the receipt of intimation of accident. The vehicle was specially constructed by the St. John Ambulance Association.

The Heath Scholarship.

The many friends of Mr. George P. Newbolt, surgeon to the Stanley Hospital, have heard with much pleasure of his successful competition for the Heath Scholarship, a prize of the value of £200. Prior to his appointment to the Stanley Hospital Mr. Newbolt was surgeon to one of the sections of the Manchester Ship Canal during its construction, where he gained a large surgical experience from the numerous accidents occurring, The subject of the essay was the Surgical Diseases of the Jaws.

Health of Liverpool.

The medical officer, Dr. Hope, reported that 375 births were registered in the city during the week ending May 30th, representing a birth-rate equal to 30·4 annually per 1000 of the population. The deaths registered during the same period amounted to 254, making a total mortality-rate equal to 20·6 annually per 1000 of the population. Of the total deaths, 88 were those of children below five years of age, and of these 53 were infants below one year of age.

June 9th.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Thornbury Board of Guardians and Small-pox.

THE Thornbury board of guardians and rural council are evidently of opinion that if a medical man attends small-pox cases he should confine his attention solely to those patients, for at the last meeting of the board on May 29th the sanitary inspector, in reply to an inquiry, said that several persons had called his attention to Mr. Lane visiting private patients and their consequent fears of the epidemic spreading. It was resolved that the clerk be instructed to give seven days' notice to Mr. Lane to terminate his agreement, and that Dr. Bond be requested to engage a medical man to attend all small-pox cases only in the district subject to the approval of the council. An amendment was proposed: "That, subject to Mr. Lane complying with such condition as attending to small-pox cases only, he shall be appointed"; but this was defeated, the resolution being carried, 15 voting for it, 1 against, and 2 neutral. It was further resolved that the cost of the medical man should not exceed five guineas weekly, and that the officers be instructed that no visitors be allowed in the hospital except in extreme cases when a minister of religion is sent for. The guardians seem to be unaware that if a medical man has been revaccinated, and uses ordinary disinfecting precautions, there is no danger of his carrying any contagion.

The Vaccination Question at Swindon.

The lesson to the anti-vaccinationists at Gloucester has had no effect upon the guardians at Swindon, for at their last meeting the vaccination question was again discussed at great length, and it was decided by 16 votes to 11 not to enforce compulsory vaccination but to await the report of the Royal Commission.

The South Wales University College.

At a meeting of the council of the University College of South Wales and Monmouthshire held on June 3rd, Lord Tredegar was unanimously elected President of the College, in succession to the Very Rev. the Dean of Llandaff, who has resigned. Lord Tredegar takes great interest in the institution, and has already given £2500 towards its funds.

The Better Housing of the Poor in Bristol.

The sixth annual meeting of the Bristol Committee for Promoting the Better Housing of the Poor was held on May 29th. The report stated that during the past year, out of a large number of houses visited, it was found necessary to call the attention of the sanitary authority to ninety-five. Of these a considerable number had been repaired and improved, some had been converted to other uses, whilst those that were past repair had been closed. There were, however, still remaining in the city a large number of houses of the above class, which from a moral and social point of view should be closed. It was also stated that Mr. Lewis Fry, M.P., wished to resign the position of chairman of the committee as he was unable to devote time to the work. Canon Cornish was accordingly elected to fill the vacancy. This society is doing good work in a quiet way. The committee visit the poorer parts of the city and if they discover any defective drainage, &c., communicate with the owners to make the necessary alterations, and if this is

Digitized by Google

not done the sanitary authority is informed, the committee and the sanitary authority working harmoniously together.

The Wells (Somerset) Board of Guardians and their Medical Officers.

The Wells Board of Guardians recently proposed that their medical officers, in addition to their duties, should also dispense medicines for their patients, and instructed the clerk to write to the four medical officers of the union asking them if they would, at an increased salary, consent in future to dispense the drugs, in addition to giving advice. At the last meeting of the guardians the clerk stated that three of the four medical officers decidedly disapproved of the proposal, while the fourth only consented to giving it a conditional trial. Some of the guardians suggested that the board should adhere to the proposed system for the medical attendants to dispense and that the said officers be asked to give a definite acceptance or rejection of the proposal by the next meeting, but on a division this was defeated, and it was eventually decided to refer the question to the General Purposes Committee.

The Cardiff Water-supply.

An alleged contamination of the water-supply at Cardiff was discussed at the meeting of the Waterworks Committee of the corporation last week, a scare having been caused by reports of a somewhat sensational nature. The engineer stated that he had received about fifty complaints and a number of samples of water. Mr. Hughes, the borough analyst, presented his analysis of a sample of Cardiff water. According to his report the water yielded no evidence of animal or sewage contamination, but it contained, apparently, more than the usual amount of vegetable or peaty matter, and Mr. Hughes was of opinion that the taint, apart from the taste and smell, was not such as to cause uneasiness, but was mainly due to fermentation of vegetable matter in the water in the service reservoir. The committee decided to arrange for seven additional ventilators to improve the ventilation of the service reservoir. It is stated that the borough analyst will make an analytical examination of the water before it enters the filter beds.

The Nursing at the Merthyr Tydvil Union Workhouse.

The committee appointed to inquire into the complaints of the two assistant nurses at the Merthyr Tydvil Union Workhouse who had recently resigned have presented their report to the guardians. It appears that the chief grievance was in respect to the dietary. The board decided to give certain extras upon the advice of Mr. Ward, the house surgeon, consequent upon which the resignations were withdrawn. Upon the recommendation of the committee it was decided to advertise for probationary nurses.

June 9th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Sanitary Congress and Health Exhibition.

A MEETING was held on Friday last at the town hall, Newcastle-on-Tyne, to make arrangements for the Congress and Health Exhibition of the Sanitary Institute in the autumn. The Mayor presided, and the meeting was attended by the following gentlemen representing the Sanitary Institute: Mr. A. Wynter Blyth, M.R.C.S. Eng., chairman of the Council; Mr. H. Law, M.Inst. C.E., chairman of the Exhibition Committee; and Mr. E. White Wallis, F.S.S., secretary. The date proposed for the meeting is Sept. 2nd to 9th. H.R.H. the Duke of Cambridge, President of the Sanitary Institute, has expressed his intention to be present at the meeting and to open the exhibition, which will remain open until Sept. 26th.

Appointment of Surgeon to the Eye Infirmary, Newcastle.

Dr. Charles Lightfoot has been selected to fill this important post. He is a son of Mr. R. Lightfoot, who for many years was a leading surgeon in Newcastle, and is one of the best-known and most respected members of the profession in the North of England. Mr. R. Lightfoot was the first, it is believed, who treated strabismus by operation in Newcastle, and for long he was known far and wide for his success in eye surgery. Dr. Charles Lightfoot has had an excellent training as an ophthalmic surgeon and much will be expected from him.

Dr. Stainthorpe of Hexham has just received the congratulations of his friends upon his eightieth birthday. He is hale and well and enjoys a hard day's work as well as many younger men. May he long be able to do so.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS)

The New Edinburgh City Hospital.

IN view of the erection of a new city hospital in Edinburgh Baillie Pollard, the convener of the Public Health Committee, has published a memorandum containing his views on the subject after having visited a number of the Infectious Diseases Hospitals on the Continent, from Budapest and Vienna to Hamburg and Copenhagen. He prefers the one-storey pavilions, but thinks that with advantages of site and purity of atmosphere two-storey pavilions might be as satisfactory. The point to which special reference may be made is his treatment of the important question of research. He says that in constructing the new hospital the city will have a unique opportunity to render, at a comparatively trifling cost, one of the most valuable services to the Edinburgh Medical School that it has ever received. That service lies in providing adequate laboratory accommodation for bacteriological research, and for the investigation of the nature, causes, and prevention of all kinds of febrile disease. The Edinburgh school has never yet been able to take its proper place in relation to this all-important field of inquiry. The prosperity of the medical school tended in no small degree to the general prosperity of the city. Anything, therefore, that the city could do to promote the interest of the medical school was a contribution to the best interests of the city itself. Down to the present time almost all the material which increased fever hospital accommodation provided had gone to waste. There were no proper means of conducting such systematic inquiry as that which is carried on in the principal centres on the continent. The opportunity to meet this great defect now lay ready to their hands. In every well-appointed fever hospital on the continent, but especially in Germany, well-equipped laboratories are found where students and graduates conduct methodical and patient investigation into every aspect of every kind of infectious disease. There is also provided a museum and a post-mortem room. It was the part of the city to provide the necessary accommodation, which it could now do in the simplest and most economical way in setting apart suitable rooms for the purpose. It might be assumed that the medical school would not be slow to do its part in making the best use of facilities so provided. Mr. Pollard's views are excellent, and his opinion as to the desirability of such a departure as he indicates will be readily granted by the profession. But when he admires the excellence of the arrangements in Germany for studying infectious diseases he must bear in mind that it is public money which subsidises all that and makes it possible. If Mr. Pollard would find the money there will be no lack of energetic and able workers found in Edinburgh for the work there; but it is quite in vain to suppose that men can live on air, however great their devotion to science may be.

Harveian Society of Edinburgh.

Dr. Peel Ritchie (Fellow and Past President of the Royal College of Physicians of Edinburgh) chose for the subject of his Harveian Oration before the Harveian Society of Edinburgh the Early Days and First Knights of the Royal College of Physicians of Edinburgh. The orator's remarks, which were very interesting, dealt with the establishment of the Edinburgh College of Physicians and its connexion with many necessary reforms in the medical profession, and as regards Scotland in preparing and publishing a Pharmacopœia. We hope to publish an abstract of the oration in a future issue.

New Cottage Hospital, Aberdeenshire.

A cottage hospital is to be erected at Bridge of Alford, Aberdeenshire, by the Alford District Committee of Aberdeen County Council. The cost will be about £1100. There will be a four-roomed cottage and a pavilion, with two wards (for six or eight patients) and nurses' room.

A Medical Staff Corps' Encampment.

On the 6th inst. the Aberdeen University Volunteer Medical Staff Corps went into camp for three days at Pitfour, Aberdeenshire. The departure from the city was marked by

Digitized by Google

a popular demonstration, which did not, however, bring good luck in the shape of dry weather, at the outset at least, to the corps, which numbered about a hundred, including officers. Colonel Ferguson of Pitfour did his utmost for the comfort of the men, and during the wet spell the riding school within the beautiful policies was placed at the service of the corps for drill. The inspection took place on Saturday afternoon to the satisfaction of the inspecting officer and amid favourable atmospheric conditions. A church parade followed on Sunday forenoon. Staff-Surgeon J. Mackenzie Booth, M.D., C.M., was in command of the corps.

June 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Army Medical Deadlock.

IN a leading article in the *Irish Times* of June 8th an unqualified contradiction is given to a statement which appears in the current number of a medical contemporary to the effect that an effort is being made by certain teachers belonging to the Dublin medical schools to induce Irish candidates to present themselves for examination for commissions in the Medical Staff under present regulations. So far, the writer states, is this from being the case that the responsible teachers in all the schools have given timely warning of the absolute necessity that candidates should obtain satisfactory assurance that the necessary reforms will be carried out before they present themselves for examination. It is pointed out that any other course would be suicidal and disloyal to their brethren in the service, whose hopes of redress depend largely on the inability of the War Department to obtain a sufficient number of medical recruits. As I have more than once mentioned in these columns the dearth of candidates for the Army Medical Service really commenced in Ireland, while the falling off in their number has always been more marked here than elsewhere. It is not likely that while the grievances which destroyed the army medical classes of Dublin remain unredressed candidates will present themselves in any number from here. The fact, however, that a deficiency of competitors in August next would probably lead to the promulgation of a new and fovourable warrant will doubtless keep back many sensible men who wish to ultimately join the service.

Mater Misericordiæ Hospital, Dublin.

This hospital has been for some years the largest of the general hospitals of Ireland, containing, as it does at present, 330 beds. A new wing has, moreover, been planned and is soon to be erected. The hospital, as is well known, was originally designed to form a square, with sides about 100 yards in length, enclosing an exercise ground for the patients. Three sides of the square are in existence, while the idea of erecting a fourth has been very properly abandoned. Instead of this a new building to contain wards for the reception of fever cases, and about 130 feet in length, will be erected to face the North Circular-road, with, of course, an entrance on that road quite distinct from the main approach to the general hospital in Eccles-street. The commencement of this new wing is now delayed only by the strike which prevails in the building trade.

The Royal Hospitals, Belfast.

On June 6th the working-men's committee and their friends paid their annual visit to the Throne Hospital, and having inspected the various departments they held a meeting, at which they passed resolutions strongly recommending the claims of the Throne Hospital, as well as the Royal Hospital, to the support of their fellow working men and women. It was stated that during the past year they had collected over £2400 from their fellow employés, the amount being subscribed in halfpennies and pennies.

Belfast Asylum.

At the monthly meeting of the governors, held on June 8th, it was reported that there were 627 inmates in the asylum and 90 at the Purdysburn Auxiliary. There is to be a friendly discussion between the board of guardians and a committee of the governors of the asylum on June 15th in reference to the often discussed question of transfer of patients to the workhouse. The committee of inspection reported that they were of opinion that the water-supply of Purdysburn Asylum was insufficient. They thought the question must be considered should artesian wells, with large cisterns for storing purposes, be made, or should a supply be obtained from another source. They also thought the new sewage works and filtering tanks were unsuitable for a large establishment.

The Study of Mental Diseases.

At the Asylum Board on Monday last a communication was received from the office of Lunatic Asylums, forwarding a copy of a letter which they had addressed in reply to a Belfast medical man, who requested to be allowed to visit the Belfast District Asylum for the purpose of studying mental diseases. The inspectors in their reply said they would be very pleased that the medical man should avail himself of any opportunities which the medical superintendent might think fit to offer him. The board of governors decided that the medical man might attend during the ordinary hours of the students' class conducted by the medical superintendent for the study of mental diseases, but that no special arrangement could be made.

Cork: the Legal Value of Medical Evidence tendered by Policemen.

The Royal Irish Constabulary are a fine body of men, but when they aspire to play the part of medical men by giving medical evidence they are undertaking the performance of duties outside their sphere. Last week a man was brought before the local bench of magistrates charged with "assaulting, wounding, and inflicting grievous bodily harm." After the ordinary evidence had been given Mr. Horne said he would require medical evidence of the grievous bodily harm. The following colloquy then ensued:—Mr. Ewart (District Inspector of Police): "Strike out 'grievous bodily harm.' The sergeant saw the wound." Mr. Horne: "Oh, no; I don't think the sergeant is competent to prove grievous bodily harm unless you have other evidence. I for one will not take that. I will either return information for trial to quarter sessions or refuse information." Mr. Ewart: "I ask you to return information on the charge of wounding." Mr. Horne: "I refuse." The sergeant was then put forward by his inspector and gave as much medical evidence as he could, but Mr. Horne, alive to his legal responsibilities, said: "We don't find grievous bodily harm and we cannot return informations, but we order a summons for common assault to be issued against him." In future similar cases the district inspector must either provide medical evidence or omit the graver charge. Should he adopt the latter course there may be a serious miscarriage of justice.

Election of Coroner for East Limerick.

Last week Dr. P. J. Cleary of Kilmallock was elected coroner for East Limerick by a large majority. The other candidates, all medical men, were Mr. Hennessy (Galbally), Mr. Lee (Kilfiane), and Dr. Connery.

June 8th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Disinfection by Formaldehyde.

I HAVE already in the columns of THE LANCET enlarged on the virtues as a disinfecting agent of formic aldehyde, giving details of experiments conducted with that gas in hospital wards. I make no apology for once more referring to such an important subject. MM. Roux and Trillat and M. Bosc publish in the *Annales de l'Institut Pasteur* (May 25th) two separate reports on the sterilising properties of formaldehyde. The experiments of the first-named collaborators were conducted in rooms whose cubic capacity varied from 70 to 1400 c.m. The destruction of pathogenic germs was absolute even in the room of the larger dimensions. The sterilisation of the air-dust and of the walls may be considered as practically perfect, the aldehyde vapour acting almost instantaneously and simultaneously in every part of the room. No danger of poisoning with carbonic oxide is incurred, although the irritating nature of the gas renders it incumbent on the manipulators to prevent its escape into the neighbouring rooms. M. Bosc states that the dry vapours of formaldehyde destroy after an exposure of five hours' duration all pathogenic micro-organisms existing on dry squares of linen, the presence of a little moisture not having an appreciable retarding effect. The spores of pathogenic fungi are

Digitized by Google

likewise destroyed if they be dry. The only germs that resist are the bacillus subtilis (of hay) and the bacillus mesentericus, neither of which possesses any practical importance. When contact with the vapour is difficult the result is precarious. Thus, of two specimens placed in a coat-pocket whose flap had been turned down one (the staphylococcus) was killed, whereas the other (bacillus coli) survived and furnished a weak culture in five days. The staphylococcus and the charbon bacillus survived exposure to the vapour when placed inside a heap of sheets and in the thickness of a mattress respectively. The wool of this mattress yielded a culture of the streptococcus. Germs placed on a mattress simply doubled on itself were, on the contrary, killed. Moist specimens were also killed when perfect access of the aldehyde vapour was ensured. Of some such moist specimens exposed in test tubes some were destroyed and others escaped. Koch's bacillus tuberculosis contained in dry sputa or in sputa triturated with sterilised sand was killed, and even fresh sputum spead on linen to a thickness of one or one and a half millimetres was disinfected. It is evident that the freer the contact of the aldehyde the more complete is the disinfection. Quilts, sheets, curtains, &c., to be disinfected should, therefore, be hung on lines, pockets should be turned inside out, and woollen mattresses unsewn. After the disinfecting process is over the windows are widely opened. A quarter of an hour later the room can be entered (the windows being still open). After two days of thorough ventilation the room is odourless and habitable. The formaldehyde does not deteriorate or decolourise any object. Formaldehyde generators are sold in Paris in the form of lamps. I had one in use in a furnished apartment the other day in a case of chicken-pox, the result being quite satisfactory. I would strongly recommend this method in preference to the old sulphur plan.

Professional Etiquette.

A considerable part of the correspondence pages of THE LANCET being devoted to points of professional etiquette, the following rules formulated by the Conseil Général des Sociétés d'Arrondissements de Paris will be of interest to your readers:—

"Tout médecin appelé pour la première fois dans une famille doit, s'il aperçoit ou apprend qu'il a été appelé à défaut du médecin traitant absent ou malade, ne donner ses soins que pendant l'absence de son confrère. Si le médecin, appelé en l'absence du médecin traitant, constate que le malade a l'intention formelle de réclamer ses soins pour l'avenir, il peut continuer à voir le malade après avoir averti son confrère. Tout médecin appelé accidentellement près d'un malade en traitement devra se borner à prescrire les médicaments nécessaires pour parer aux accidents du moment et ne se représenter chez le malade que s'il est appelé en consultation par le médecin traitant. Tout médecin appelé près d'un malade, dans le cours d'une maladie aiguë ou chronique régulièrement suivie, fera ses efforts pour faire rappeler le médecin traitant; s'il échoue il doit prévenir, sans délai, le confrère auquel il succède. Tout médecin appelé en consultation devra s'abstenir, vis-à-vis du malade et de son entourage, de toute réflexion. La consultation étant faite à part, le traitement convenu sera fait par le médecin ordinaire. Le médecin appelé en consultation par le médecin traitant ou par la famille ne devra retourner voir le malade que s'il est appelé à nouveau et autorisé par le médecin traitant. Il est d'une bonne confraternité d'accepter un médecin consultant proposé par la famille, quels que soient son âge, son grade, ou sa situation, pourvu que son honorabilité personnelle et professionnelle soit indiscutable. Le cabinet de consultation est un terrain neutre où le médecin peut donner ses conseils à tous ceux qui les lui réclament, et quel que soit le médecin traitant."

June 11th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Direct Vision by Means of the "x" Rays.

PROFESSOR BUKA of the Technical College (Berlin) announces in the *Deutsche Medicinische Wochenschrift* that he has succeeded in directly observing by the "x" rays without the aid of photography, not only the bones, but also some of the internal organs. The proceeding he describes as follows. Instead of a photographic sensitised glass-plate he uses a screen consisting of a plain glass plate closely covered with paper in which a U-shaped window is cut out. Barium platinocyanide is very evenly spread over this U-shaped space, and the whole is then covered with a second layer of paper. The remainder of the apparatus is the usual covered Crookes's tube, a Ruhmkorff induction coil, &c. When the screen is placed before the luminous vacuum tube the U-shaped space becomes fluorescent, and if the outspread hand is brought between the screen and the vacuum tube the bones, which of course are not penetrated by the "x" rays, appear on the screen as dark shadows with outlines as distinct as in a good photograph. They may thus be directly observed, and the movements of the joints are equally visible on the screen. A still more striking phenomenon was the direct observation of the ribs, the respiratory action of which was quite perceptible; and in addition to the osseous parts of the thorax there came into view a dark mass on its left side showing the distinct outlines of the heart. The liver also became visible, but the lungs, which are penetrated by "x" rays, were not to be seen. Foreign bodies also could be directly observed. Professor Buka lays stress on the fact that by his method it is possible to explore the living body in all directions by simply moving the screen and the vacuum tube, whilst by the photographic method, not only would a long series of pictures on glass be necessary for the same purpose, but the photographic method has hitherto failed in depicting the internal organs.

The German Surgical Association.

The association, which has just celebrated its twenty-fifth anniversary, was founded in 1872, when those civil and military surgeons who had taken part in the Franco-German war gathered together in Berlin to discuss their campaigning experiences. Regular annual meetings have since then been held in Berlin under the presidency of the late Professor von Langenbeck, the founder of the association, who acted as chairman until removed by death. The most eventful meetings were those of 1873, when Professor Esmarch described his method of artificial anæmia for operations on the extremities; of 1874 and 1875, when Professor Lister's antiseptic treatment was discussed at length; and of 1891, when Professor Koch's tuberculin was the principal theme. By 1891 the membership of the association had greatly increased and it was able to inaugurate its new home, Langenbeck House, erected in commemoration of its distinguished president. Foreign surgeons, and especially visitors from Great Britain, have always taken part in the proceedings, and in 1889 Professor Victor Horsley read a paper in excellent German on the Injuries of the Motor Area in the Cortical Substance of the Brain. It is worth mentioning, too, that of the nine honorary members three are English—Sir Joseph Lister, Sir James Paget, and Sir Spencer Wells. The celebration began with a concert on the evening of May 25th in the Great Hall of the Reichstag Palace, courteously placed at the disposal of the members by the President of the Parliament. On the next morning a formal meeting took place in Langenbeck House, the great hall of which was adorned with oil paintings of the former presidents and the honorary members. The meeting was attended by a very distinguished assembly, including delegates from the Berlin professional societies and from foreign surgical associations, as well as representatives of the Government, the University, the town council, the Army Medical Staff, and the Red Cross Organisation. All the leading German surgeons and many foreign ones were also present. The Royal College of Surgeons of England was officially represented by Mr. Reginald Harrison and Mr. John Langton. Sir Spencer Wells also took part in the proceedings. The chairman, Professor von Bergmann (Berlin), in his presidential address welcomed the assembly and especially the delegates, gave a short account of the history and the aims of the association, and finally an obituary of the members deceased during last year. A series of papers on different subjects illustrative of the present state of surgery was then read by several of the leading members especially appointed for this purpose by the committee and a banquet at which the delegates proposed the toast of the association closed the first day's proceedings. On May 28th the members of the Congress and their ladies were entertained at Krolls Theatre by the Berlin Surgical Society. The evening began with a series of *tableaux vivants*, acted by Berlin surgeons and their ladies, and depicting the history of German surgery from the time of the ancient Teutons till the modern era. The performance was honoured by the presence of the Emperor and Empress, and was followed by a supper and a concert. During the proceedings the question of international surgical congresses, as suggested by American surgeons, which had been adjourned at the last year's meeting, was discussed. It was resolved unanimously that the Congress should assemble every fourth year; that the members of the great national surgical associations should take part in it; that from those countries where such associations do not exist only a limited number of surgeons should be admitted; that the official languages should be German, English, and French; that a committee of the country where the Congress is held should organise

Digitized by Google

the meeting; that questions of general and immediate interest previously selected by a committee should have precedence, and that other subjects should be discussed only after those questions had been exhausted. The forthcoming Congress will probably be held in London in 1900. A detailed account of the papers read at the meetings of the association will appear in the next issues of THE LANCET.

June 8th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Anthropometry in Italy.

BIOLOGY in its wider and more practical sense will find much to profit by in the elaborate work now given to the world under the following title: "Antropometria Militare. Risultati ottenuti dallo Spoglio dei Fogli Sanitari dei Militari delle Classi 1859-63. Eseguito dall' Ispettorato di Sanità Militare, per ordine del Ministero della Guerra" ("The Anthropometry of the Soldier. Results obtained by gleaning the Sanitary Literature of the Army on the Levies taken in 1859-63. Executed by the Inspecting Staff of Military Hygiene, by order of the War Office.") No military power in Europe has yet, I believe, produced a statistical return so rich in material of anthropological and ethnographical interest as this just issued in Rome. The conception of such a compilation is due to Lieutenant-Colonel Dr. Salvatore Guida, who first proposed it in the *Giornale di Medicina Militare* in 1879. At the military levies of non-Italian countries the statistics used to be confined to stature and the perimetry of the chest. Of late years Germany took the lead in appointing a special scientific commission to assist at the inspection of the incipient soldier and on its own account to take note of other measurements. Dr. Guida, in the article above referred to, was of opinion that anthropology and ethnography (to say nothing of medico-military practice) would have much to gain by carrying the inspection some steps further and filling up for each soldier enrolled a paper representing his health conditions at the first inspection, to be followed periodically by other entries, forming a running commentary on his health vicissitudes during his military career (invaliding, leave, withdrawal from service, death), particularly affecting his stature, weight, and thoracic circumference in successive years. At the close of his military services by retirement or death the paper (*foglio*) of each individual was to be consigned to a central bureau charged with the general review of these *fogli*. The War Office fully accepted Dr. Guida's proposal, and the compilation on its lines was to include the period between 1859-63. No fewer than 300,000 *fogli*, attesting the physical condition of as many soldiers at the first inspection up to death or withdrawal from active service, were thus available, giving the variable characteristics of physique (stature, weight, thoracic girth) with their variation in each year; then the non-variable or slightly variable physical qualities (the colour and form of the hair, the eyes, the complexion, the teeth, eyebrows, the forehead, the nose, the mouth, the chin, the general outline of the visage, and the diameter of the head); and, finally, the physical defects and the illnesses undergone. The *spoglio* (gleaning) of these *fogli* and their scientific arrangement were performed under the direction of Captain Ridolfo Livi, M.D., and the results under the title given above have just been published in a volume of 420 pages, with relative atlas of twenty-three plates and other subsidiary indications. The whole publication amply justifies the proposal of its original author, Dr. Salvatore Guida—a proposal which elicited the cordial approbation of anthropologists and ethnographers like Virchow, Rancke, De Lapouge, Ammon, Olorez, Lagneau, Chervin, Dujardin, Galton, Beddoe, Kollmann, Boas, Ripley, and others.

June 5th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Suprarenal Extract.

DR. VELICH has been experimentally investigating the action of suprarenal extract, and the results as published by him entirely confirm those of Oliver and Schäfer. He observed an increase of the blood pressure, irritation of the vagus nerve, and an acceleration of the pulse after injection of atropine or section of the medulla oblongata. Increase of the blood pressure also follows on sections of both splanchnic nerves or on bleeding, and is due to the contraction of the small vessels and capillaries of the abdominal viscera. The acceleration of the heart's action is produced by the influence of the extract on the heart. After the injection of suprarenal extract the extirpated heart pulsates more strongly than is normal.

Zymotic Diseases during 1895.

The report on Zymotic Diseases in Austria during 1895, which has just been published by the Sanitary Commission, shows that there were 2901 cases of small-pox, 2366 of which occurred in Galicia; there were some outbreaks in Styria, but no case has been registered in Tyrol and Vorarlberg. The report also shows an increase of 14,055 cases of scarlet fever above the number recorded in the previous year; this disease was prevalent in Moravia, Bohemia, and Istria, and the death-rate amounted to 18·8 per cent. Diphtheria exhibited an increase in Dalmatia and Galicia; the death-rate fell to 31·6 per cent., against 37·6 per cent. in 1894 and 43·8 per cent. in 1893. There were also 19,462 cases of enteric fever, against 36,349 in 1892.

The Antitoxin Treatment of Diphtheria.

Dr. Zuppinger has published in the *Klinische Wochenschrift* a report on the Antitoxin Treatment of Diphtheria in the Rudolf Hospital for Children. During 1895 there were 160 admissions of children suffering from diphtheria, of whom 120 recovered and 40 died. Following the classification of Behring he distinguishes three varieties of diphtheria—pharyngeal, pharyngo-nasal, and pharyngo-laryngeal. Among the 160 children there belonged to the first group 72 cases with 8 deaths (a mortality of 11 per cent.), to the second group 32 cases with 13 deaths (a mortality of 40 per cent.), and to the third group 56 cases with 19 deaths (a mortality of 33 per cent.). With respect to the age of the patients there were 13 children in their first year, of whom 9 died (69 per cent.); 32 in their second year, of whom 12 died (37 per cent.); 57 between their second and third year, of whom 10 died (17 per cent.); 32 between their fourth and sixth year, of whom 6 died (18 per cent.); and 26 at higher ages, of whom 3 died (11 per cent.). In some cases there was infiltration and erythema resembling the eruption of scarlet fever; sometimes the children complained of pains in the leg. In cases of croup with grave symptoms the dose injected during the first twelve hours was from 2000 to 3000 units, and if no improvement resulted a further injection with from 1000 to 1500 units was given. In slight cases 1000 to 1500 units were sufficient. In spite of these large doses no important disturbance was observed. In 20 cases there was albuminuria, and in 3 there was post-diphtheritic paresis of the soft palate. Serum was injected in 51 out of the 56 cases of laryngeal diphtheria, with the result that 36 recovered (71 per cent.) and 15 died. In 12 cases the stenosis disappeared, in 36 cases intubation was performed, and in 3 cases tracheotomy. Among the cases in which intubation was employed 14 died (38 per cent.), and 1 case in which tracheotomy was performed died from bleeding due to erosion of the innominate artery. Bacteriological examinations were made in 122 cases, including 67 pharyngeal cases, 28 laryngo-nasal cases, and 27 laryngeal cases. In 17 cases belonging to the first group Löffler's bacilli were found, in 25 cases these organisms were associated with streptococci and staphylococci, and in 25 cases there were only staphylococci. There were 45 pure forms and 44 combined forms of diphtheria, while in 33 cases no Löffler's bacilli were to be seen; of the 45 cases of pure diphtheria 17 died, whereas the death-rate of the combined forms amounted to 6 and that of the last group to 7. In order to show the presence of antitoxic serum in the blood subsequently to its subcutaneous administration Dr. Loos examined the blood of a boy three years of age suffering from varicocele. It possessed only a trifling antitoxic quality, but a sample taken some hours after the injection of 2000 units of antitoxin showed a decided increase of antitoxic power. It is, further, of great importance to decide whether the formation of antitoxic substances ceases on recovery from diphtheria. Cases not uncommonly occur where Löffler's bacilli are found in the mouths of healthy children and an examination of the blood shows that it possesses a highly antitoxic power. Children who have recovered from diphtheria may also have virulent

Digitized by Google

bacilli in the pharyngeal mucous membrane without again falling ill.

Tuberculous Leprosy.

A case of tuberculous leprosy has been exhibited by Dr. Rille at a meeting of the Dermatological Society. The patient was a boy aged fifteen years, who was admitted to hospital some months ago, and was treated with arsenic, thyroid tablets (about 1000 in number), and finally with an ointment containing Goa powder. Some nodes have disappeared, but at present there are several in the pharynx, larynx, and conjunctiva. The case is interesting from the presence of reddish nodes on the sole of the foot—a place where the occurrence of leprosy has been denied by writers such as Boeck and Danielssen—the lesion being supposed to be syphilitic. Histological examination showed the bacilli and the typical structure of nodes. The patient came from Roumania, where of late years about a hundred cases of leprosy have been observed. There is no alteration of sensibility, and no albuminuria or implication of the internal organs.

Insurance against Sickness.

Compulsory insurance against sickness among the working classes was introduced some years ago, and the Government has just submitted to Parliament a further Bill on the same subject. The medical profession does not seem to realise the importance of this fact, for, with the exception of the Vienna Medical Chamber, no society has hitherto taken measures to oppose this Bill. Indeed, the impoverishment of the profession is increasing to such a degree that in Vienna there are many young medical men who no doubt wish for the introduction of this compulsory scheme and would be satisfied with receiving a penny a visit. The medical chambers have but little influence and any opposition of theirs to this Bill will be unsuccessful. Notwithstanding its high scientific position the profession in Vienna and in Austria has no business organisation, and its boards possess so little disciplinary power that they are not even able to check medical advertising.

Honours to Medical Men in Austria.

During this week high distinctions have been conferred upon Professor Neusser and Professor Wiederhofer. Professor Neusser, who is one of the most eminent authorities on internal medicine, has been appointed a Privy Councillor, an honour which is so much the greater as he is, perhaps, the youngest man in Austria whom the Emperor has distinguished in such a degree. His name is widely known by his researches on the diseases of the blood and by his chemical and bacteriological knowledge. His lectures are attended not only by students, but also by a great many physicians who appreciate his skilful diagnoses. Professor Wiederhofer has received a letter from the Emperor wherein His Majesty pays a highly flattering tribute to his merits and thanks him for his attendance on the deceased Archduke Karl Ludwig.

June 8th.

BRITISH ORTHOPÆDIC SOCIETY.—This Society met at Birmingham on May 30th, 1896. The new General Hospital, the General, the Children's and the Royal Orthopædic Hospitals were visited by the members. The meeting was held at the Birmingham Medical Institute. Mr. Wm. Thomas showed cases of Congenital Torticollis, severe Lateral Curvature in a male adult, Congenital Absence of Metacarpus and Phalanges, and Double Congenital Displacement of the Hip and Talipes, treated by Tarsectomy.—Dr. Warden showed a case of Partial Absence of the Fibula, Marked Lateral Bending of the Tibia, associated with Congenital Talipes Valgus.—Mr. E. Luke Freer brought forward cases of Congenital Hip Displacement, Rhachitis Adolescentium, Relapse after Tarsectomy for Double Talipes Equino-Varus, and Cervical and Upper Dorsal Scoliosis.—Mr. Keetley and Mr. Openshaw discussed the cases, and Mr. W. Thomas, Dr. Warden, and Mr. Luke Freer replied.—Mr. Robert Jones brought forward an interesting case of Recrudescent Rickets in a girl eight years of age. He stated that he had seen twenty or thirty cases, and in most of these the lower extremities alone were affected; in some, as in the present case, the head, chest, and upper extremities participated in the deformities.—Mr. Tubby drew attention to the fact that hitherto no microscopical examination of the bones had been made in cases of so-called "late rickets."—After votes of thanks to the Birmingham members for their hospitality and to the Council of the Birmingham Medical Institute the proceedings terminated.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE Council was much gratified on Monday last by the presence of Sir Henry Acland for an hour or more during the discussion on the Apothecaries' Hall of Ireland. He seemed to enjoy his visit to old friends and to the new room, and said to one member that it made him feel quite young again.

The Recommendation of the Council on instruction in practical midwifery has at last been altered and brought more into consonance with reason and the nature of the case. The Council has resolved that henceforth the alternative of three months' attendance on the in-door practice of a lying-in hospital shall be to have been present at not less than twenty labours, at least five of which have been conducted *throughout* under the direct supervision of a registered practitioner. The word "throughout" is meant to cover the period of the puerperium as well as the mere labour. The Scottish schools will doubtless bring themselves as soon as they can into harmony with this reasonable recommendation on one of the gravest subjects of medical education. It is only fair to them to say that they have been bound by the Commissioners of the Scottish Universities, and that their representatives, including Dr. Tuke, chairman of the Education Committee, have been earnest parties to the alteration. The result must be so far satisfactory to Dr. Glover and those who for years have shown the absurdly loose and inadequate nature of the Council's recommendation on this important subject.

Not the least important part of the Council's proceedings was the consideration of a letter from the Medical Defence Union, dated May 28th, on the bearing of the recent judgments in the cases of Bridgewater and Frickhart respectively. Bridgewater practised and advertised extensively at Cardiff under the title Dr. Bridgewater, M.D., U.S.A. Mrs. Frickhart's case was different. She had been on the Register as a L.K.Q.C. Phys. Irel. and M.D. of Zurich. For violating the rules of her college by advertising, she was deprived of her only British diploma. The Council also saw fit to remove her name from the Register after vainly attempting to procure her appearance before them to answer for her conduct. The Medical Defence Union regard their failure to get convictions in these cases—a failure so far endorsed by the High Court—as a proof of the nee for amendment of the Medical Acts so as to make them more efficient as a means for enabling the public to judge between qualified and unqualified practitioners. It will be seen that Mr. Muir Mackenzie, from his statement to the General Medical Council, is not yet satisfied that it was the Acts themselves that were to blame so much as the mode of presentin the cases to the Court. The cases of apparent breach of the fortieth clause are numerous, and there should be no difficulty in putting Mr. Muir Mackenzie's views to the test. The sooner this is done the better. Though the judges do not pretend to have settled or decided anything by their recent action, it has had the effect of encouraging pretenders of all sorts and discouraging those who do their best at great cost to defend the public and the profession.

It will be observed that the Council dealt with several cases of charges of infamous behaviour in a professional respect. In three the Council removed the names of the offending practitioners; in another instance the practitioner was found not guilty of the offence. Even in cases where the practitioner's name is removed there are very

Digitized by Google

different degrees of blame. In one of the recent cases—though reported by a coroner and associated with the death of a child suffering from extensive pneumonia, apparently undetected by the unqualified assistant and never seen by the principal—the decision of the Council seemed to come on the offender as a surprise, though the Council has been warning the profession for years of the risks of such methods of practice.

Mr. Teale has been placed on the Examination Committee of the General Medical Council.

There was a very significant unanimity in the Council in favour of a more thorough preliminary examination, and Mr. Bryant carried a resolution asking the Education Committee to consider whether the time has not come for erasing from the list of recognised preliminary examinations the examination for *second*-class certificate (of first or second division) of the College of Preceptors. The Commissioners of the Scottish Universities have set an admirable example of raising the preliminary standards. The immediate result is to diminish the number of their students. But the ultimate and not remote effect is to raise the standard of education and the public estimate of their degrees.

THURSDAY, JUNE 4TH.

IN THE LANCET of June 6th we reported at length the proceedings during the first two days of the session of the Council, and stated that on this, the third day, the business was chiefly the consideration of penal cases. We now take up the report at that point.

The Case of James Charles Ady.

The first case considered was that of James Charles Ady of Brighleigh, Trent-road, Brixton-hill, London (registered in Scotland May 7th, 1878, as "Lic. R. Coll Phys., Edin., 1878, and Lic. R Coll. Surg., Edin., 1878"), who had been summoned to meet the following charge formulated by the Council's solicitor:—

"That, in conjunction with a woman named Graham, he held himself out to persons who consulted him and the said female as being ready, in return for a sum of money, to treat pregnant women in such a manner as to cause them to be delivered of stillborn children, or, in the event of a child being born alive, to procure some one to take over the child in such a way that the mother would never hear of it again."

Mr. Ady appeared without professional assistance, while Mr. Horace Avory, on behalf of the *Sun* newspaper, attended to support the charge. The latter opened the case with a speech and thereafter called as witnesses two representatives of the *Sun* newspaper who had interviewed Mr. Ady and the woman Graham. Mr. Ady cross-examined one of these witnesses. Subsequently he was heard in his own defence, and he called Mrs. Minnie Graham, who gave evidence in support of his denial of the charge. In answer to members of the Council he admitted that he was the Mr. Ady who had at one time been in practice at Rangoon, and who while there had had his name struck off the list of members of the British Medical Association for no reason that had been explained to him. Strangers having, by direction of the Council, withdrawn, the Council deliberated on the case *in camerâ*. At the conclusion of the deliberations, on motion made from the chair, it was resolved:—

"(*a*) That the Council do proceed at once to pronounce its judgment on the case. (*b*) That the charge made against Mr. James Charles Ady has been proved to the satisfaction of the Council. (*c*) That the further consideration of the charge against Mr. James Charles Ady be not adjourned until the next session. (*d*) That Mr. James Charles Ady is judged by the Council to have been guilty of infamous conduct in a professional respect, and that the Registrar be directed to erase from the Medical Register the name of James Charles Ady."

Strangers, including Mr. Ady, having been re-admitted, the PRESIDENT announced the finding of the Council.

Shorthand as an Optional Subject.

The REGISTRAR read the following letter:—

"50, Queen Anne-street, Cavendish-square, London, W.,
"April 9th, 1896.

"DEAR SIR RICHARD QUAIN,—I beg to transmit a petition to the General Medical Council which will be supported by Sir Dyce Duckworth. It is signed by 180 members of our Society of Medical Phonographers and signed with approval by Sir Joseph Lister, Sir Russell Reynolds, Sir John Williams, and (individually) Mr. Christopher Heath.

"Its object is the promotion of the acquisition of shorthand before medical study is commenced by making it an optional but mark-bearing subject at the preliminary examination and sanctioning this course.

"Other signatures and many other approvals have yet to come in and will be sent before the meeting of the Council. Since the petition is now, however, effectively supported, I beg, as President of the society, to send it in, in the hope that some consideration of the means of giving effect to it, in the event of approval, may be possible before the meeting of the Council. "Very truly yours,
"W. R. GOWERS.

"To the President of the General Medical Council."

The REGISTRAR also read a statement to the effect that on May 16th Dr. Gowers stated that at the ordinary examinations of the College of Preceptors shorthand was already an extra optional subject, and that there would be no difficulty in having it made such at the special examination held for medical candidates if the Council expressed a wish that it should be done.

The text of the petition has already been published.

Sir DYCE DUCKWORTH recommended that this petition should receive the most careful consideration of the Council. Although he could not believe there could be much difference of opinion as to the advisability of adopting the course that the petitioners asked them to take, he yet thought the question involved was too large a question to be debated in the Council sitting as a Council, and as it was an educational matter it should be laid before the Education Committee for its consideration. He moved to that effect, suggesting that the committee should submit a report on the subject during the present session.

Sir WILLIAM TURNER seconded the motion. He did not think there was any necessity to say anything on the merits.

The motion was unanimously agreed to.

Dr. TUKE, chairman of the Education Committee, hoped the Council would not ask for a report this session. The matter was no such simple one as it looked.

Sir WILLIAM TURNER saw no occasion to report this session. The matter was not one of urgency.

The Case of George Ingersoll Currah.

The Council proceeded to consider the case of George Ingersoll Currah of 70, Hyde-road, Hoxton (registered in England, Nov. 22nd, 1880, as Lic. Soc. Apoth. London, 1880, with the address Belmont House, Falmouth), who had been summoned to appear on the following charge, as formulated by the Council's solicitor:—

"That he acted and acts as cover to an unqualified person named Charles Keating, who, acting, or purporting to act, as his (Currah's) assistant, was permitted, authorised, and enabled by him to carry on medical practice and administer medical treatment to patients as if he were a duly qualified and registered practitioner, and in such a manner as to lead those on whom he attends to believe that he is so duly qualified and registered."

Mr. Currah appeared for himself and Dr. Bateman represented the Medical Defence Union. The latter stated that the case was originally reported to the Medical Defence Union by Mr. Westcott, one of the coroners for the East London district. It arose out of an inquest on a child named Webster, whose mother had gone to Mr. Currah's chemist's shop at 92, St. John's-road, for medical assistance and had been served with medicine by Mr. Keating, to whom it was stated she had spoken as "the doctor" without contradiction on his part.

Mr. CURRAH informed the Council that Mr. Keating had been engaged by him to attend the shop in the capacity of a chemist's assistant, and had received strict orders from him never to prescribe or interfere in any way with the medical practice of the accused. His interference in the case of the child Webster was, therefore, in disobedience of orders, and had led to his immediate dismissal. Keating, however, had afterwards resided with the people who occupied the apartments above the shop.

The Council having further considered the case in private passed a series of resolutions similar to those adopted in the Ady case, the final resolution being as follows:—

"That Mr. George Ingersoll Currah is judged by the Council to have been guilty of infamous conduct in a professional respect, and that the Registrar be directed to erase from the Medical Register the name of George Ingersoll Currah."

The Council adjourned.

FRIDAY, JUNE 5TH.

The Council resumed its work, Sir RICHARD QUAIN presiding.

The Case of Gordon Griffiths Jones.

The Council proceeded to the consideration of the case of

Digitized by Google

Gordon Griffiths Jones, of 15, Welbeck-street, London, registered in England June 18th, 1883, as Lic. Fac. Phys. Surg. Glasg., 1883, and Lic. R. Coll. Phys. Edin., 1883, who had been summoned to answer the following charge, as formulated by the Council's solicitor—viz.:

"The complaint has relation to the medical practice carried on by an unregistered person named David Jones at 15, Welbeck-street, and 10, Dean-street, Soho, and by the complaint it is alleged—

"1. That G. G. Jones, being a duly qualified registered practitioner, covers the unregistered practitioner, and by his assistance and association with him in his practice and the aid of his professional qualifications enables him to carry on a medical practice as though he were duly registered.

"2. That in the carrying on of the said practice G. G. Jones promotes and associates himself with methods of obtaining and attracting patients which are professionally discreditable—that is to say, by systematic advertisements of cures practised by the said unregistered person and publications invoking persons to resort to the unregistered person for such cures."

Dr. BATEMAN, of the Medical Defence Union, made a statement and presented evidence in support of the complaint. He explained that the person with whom Mr. Jones associated was his father, Mr. David Jones, who was formerly on the Medical Register and who was removed from it in consequence of a misdemeanour.

Mr. MUIR MACKENZIE read the statement of defence prepared by Mr. Jones. In this statement it was said by Mr. Jones that his father had been in practice as a homœopath for thirty years at 15, Welbeck-street, and his name had been erased from the Medical Register in 1861. He (Mr. Jones) understood covering to mean a registered practitioner helping and aiding and protecting an unregistered and unqualified man with no medical or surgical pretensions. He was not doing this and never had done so. No one covered his father during the seventeen years prior to 1883 when he (the son) qualified. His father did not require covering then nor did he now. His father's name was erased from the Register in 1861, and after paying his debt to his country according to law he considered his wrong expiated, and having a family to provide for sought to reclaim his steps and resume the practice of his profession. He accordingly took the L.R.C.P. London in 1865, but information having been laid against him for his former misconduct his name was removed from the roll of Licentiates. If he (the son) had erred in associating himself too closely with his father in his practice he was sorry, but he would respectfully request the Council to consider the feelings which he as a son must have felt, and still felt, at the continued persecution directed against his father. As regards the advertising he had absolutely nothing to do with it and he did not think it was for him to dictate to his father in what manner he was to conduct his affairs.

Mr. JONES, in reply to Dr. THORNE THORNE, said he was prepared if the Council desired it to dissociate himself entirely from his father's practice. In reply to Sir DYCE DUCKWORTH, he said that his father had a private hospital and it might be that the advertisements of that institution were carried about the streets by sandwich men, who also gave away handbills.

The Council then deliberated in private, and, having passed the usual series of resolutions, readmitted the public, on which

The PRESIDENT informed Mr. Jones that the charge made against him had been found proved to the satisfaction of the Council, who therefore judged him to have been guilty of infamous conduct in a professional respect and had directed the Registrar to erase his name from the Medical Register.

The Case of John Hamilton Foley.

The Council next proceeded with the case of John Hamilton Foley of Westdene, Locks Heath, Titchfield, Hampshire (registered in Ireland on Sept. 24th, 1883, as Lic. R. Coll. Surg. Irel., 1883, and Lic. K. Q. Coll. Phys. Irel., 1885), who was summoned to appear to answer the following charge as formulated by the Council's solicitor—viz.:

"That, being a registered medical practitioner, he acts as cover to an unqualified person named Walter John Oliver, enabling and authorising the said Walter John Oliver, under cover of his presence and qualifications, to visit and administer medical treatment to patients and carry on a medical practice as though he had been duly qualified. The place where such medical practice is carried on is at Titchfield, Hampshire, and in the neighbourhood of that place."

Mr. Foley attended with his solicitors, Mr. Rodgers and Mr. Craig. Dr. Bateman, who was present, said that he did not appear for the Medical Defence Union as prosecutors, but simply to watch the case on behalf of Mr. Elliott, a practitioner who had formerly employed Mr. Oliver, but had severed the connexion with him so soon as attention was called to the fact that he was following a course of conduct condemned by the Council. It was explained by Mr. Farrar, the solicitor to the Council, and Mr. Muir Mackenzie, the legal assessor, that the inquiry was one instituted by the Council on the complaint of five general practitioners resident in the Titchfield district, whose memorial contained the evidence in support of the charge. Mr. Rodgers read documents bearing on the charge, and Mr. Foley submitted himself to answer questions by members of the Council. It appeared that accused's agreement with Mr. Oliver provided for the latter's employment as assistant, dispenser, and bookkeeper, with no interest in the profits of the practice. Mr. Oliver had been long resident in the district, he was a very popular man with many friends, and Mr. Foley in engaging him had in view his obtaining a companion in Mr. Oliver, who, he thought, would be useful to him in the establishment of a practice. Mr. Oliver had seen to some trifling cases, but no patients that Mr. Foley had not seen, and though he, perhaps, had attended cases of labour, which an unqualified man was allowed to do, these cases had been visited by Mr. Foley himself either the same evening or the following morning. Mr. Foley did not reside at the surgery, but as near to it as he could obtain suitable apartments until a house he was building at present could be completed. Mr. Oliver's name in no way appeared in connexion with the practice, and he had no door-plate showing that he professed to be a medical practitioner. Mr. Foley had never allowed Mr. Oliver to hold himself out as a qualified person. He had not been introduced to the practice by Mr. Oliver, but had obtained it through a medical agent in London, who had been applied to by some old residents in the district for a practitioner to settle amongst them. Mr. Rodgers having addressed the Council on behalf of Mr. Foley the Council deliberated in private. On the public being readmitted,

The PRESIDENT announced the decision that had been come to. He said it had not been proved to the satisfaction of the Council that Mr. Foley was guilty of the charge against him. Therefore Mr. Foley was acquitted, but the Council desired that he should caution Mr. Foley to be careful in what he did in future, for should that gentleman be again summoned to appear before them the Council would view most seriously his conduct.

The Council adjourned.

SATURDAY, JUNE 6TH.

The Council resumed to-day, Sir RICHARD QUAIN being in the chair.

The Apothecaries' Hall of Ireland.

Mr. TICHBORNE informed the Council that he had received a letter from Dr. James Byrne Coleman, one of the suggested examiners in medicine for the Apothecaries' Hall of Ireland, saying it was a mistake to describe him as Examiner in Medicine in the Royal University of Ireland, and asking that the description might be rectified in the memorial. Mr. Tichborne said he could not account for the mistake that had evidently been made.

The Case of Clement Henry Sanders.

The Council dealt with the case of Mr. Clement Henry Sanders (registered as in dental practice before July 22nd, 1878), who had been summoned to answer the following charge, as formulated by the Council's solicitor—viz.:

"That, being a duly registered dental practitioner, you act as cover of and by lending your name and assistance enable an unqualified and unregistered person named Müller to carry on a dental practice and to practise dentistry and dental surgery in all respects as if he were a duly qualified dental practitioner."

The REGISTRAR having read this charge, also read the following report from the Dental Committee:

"The case of Clement Henry Sanders having been referred to them by the Executive Committee to ascertain the facts in regard to such case, the Dental Committee find the facts to be as follows:—(*a*) That Clement Henry Sanders was registered in the Dentists' Register on Aug. 13th, 1884, as having been in practice before July 22nd, 1878, and his address in the Dentists' Register is 88, Queen-street, Exeter; (*b*) that a practice of dentistry for gain is carried on at 88, Queen-street, Exeter, in the name of the said Clement Henry Sanders; (*c*) that Clement Henry Sanders has a dental surgery at Okehampton; (*d*) that Clement Henry Sanders carries on a dental practice at Aldershot; (*e*) that Clement Henry Sanders visits Exeter once every ten days or a fortnight, where he sometimes remains for two or three days at a time, and that the practice at Exeter is carried on in his absence by an unqualified person named Müller; (*f*) Mr. Sanders gave an undertaking to place a qualified assistant in charge of the practice at Exeter and Okehampton at once."

Mr. Sanders did not appear, but was represented by Mr.

Digitized by Google

Johnston Watson. Mr. R. W. Turner appeared for the British Dental Association.

In answer to an observation by the PRESIDENT,

Mr. WATSON stated that Mr. Sanders had carried out the undertaking made to the committee. "At once" was of course to be construed as meaning "a reasonable time," and since April 29th last he had had the services of a qualified assistant. He submitted that in these circumstances the Council would be properly advised if they took no steps against Mr. Sanders.

Mr. TURNER, who contended that "at once" should have meant an appointment of a qualified assistant much earlier than April 29th, mentioned that when the case first arose the British Dental Association had stated that their desire was rather to have it made clear that the resolutions of the Council in respect to "covering" were not to be treated as a dead letter than to unduly press the charge against the accused.

After the Council had considered the case in private,

The PRESIDENT announced that the charge made against Mr. Sanders had been proved to the satisfaction of the Council, but they had resolved, instead of proceeding to pass judgment, to postpone further consideration of the case until the session in November next. The Council would then expect Mr. Sanders himself to appear before them and give them an assurance that his conduct was satisfactory.

THE PENAL SECTIONS.

The Council spent the rest of the sitting *in camerâ* discussing documents from the Medical Defence Union with reference to the working of the penal sections of the Medical Acts.

The Council adjourned.

MONDAY, JUNE 8TH.

The Council resumed, Sir RICHARD QUAIN being in the chair.

Penal Sections of the Medical Acts.

The Council sat again *in camerâ* for some time discussing the letter of the Medical Defence Union with regard to the working of the penal sections of the Medical Acts.

In this letter the Council of the Medical Defence Union directed special attention to Section 40 of the Act of 1858, which ran as follows:—

"Any person who shall wilfully and falsely pretend to be or take or use the name or title of a physician, doctor of medicine, licentiate in medicine and surgery, bachelor of medicine, surgeon, general practitioner or apothecary, or any name, title, addition, or description implying that he is registered under this Act, or that he is recognised by law as a physician, or surgeon, or licentiate in medicine and surgery, or a practitioner in medicine, or an apothecary, shall, upon a summary conviction for any such offence, pay a sum not exceeding twenty pounds."

The Council of the Medical Defence Union recounted various circumstances connected with prosecutions under this section and concluded by saying:—

"We venture to submit that the facts and circumstances briefly herein enumerated are sufficient to indicate that the Medical Act does not, as framed and construed, fulfil the purpose for which it was enacted—viz., 'to enable persons requiring medical aid to distinguish qualified from unqualified practitioners,' and, further, that, owing to the ambiguous language in which Section 40 is framed, the result of each prosecution is dependent upon the interpretation placed upon such sections by each individual magistrate, and that no finality can be reached so long as the law is, as Mr. Justice Henn Collins stated, 'in a fog.' We, the Council of the Medical Defence Union, beg to urge most earnestly, in the interest alike of the public and the medical profession, that your Council will take such steps as may be necessary to obtain an amended Act which will prevent the possibility of such varied interpretations of the law in the future, so that prosecutions may be successfully conducted against unqualified practitioners, and that the proper value of qualification and registration shall be thereby legally established."

The PRESIDENT, when the Council re-admitted strangers, asked Mr. Muir Mackenzie to make a statement with reference to the letter.

Mr. MUIR MACKENZIE said: In answer to the question upon which my opinion is asked, which I understand to be whether it is desirable that this Council should submit to Parliament a Bill for the amending of the Medical Acts by altering the provisions of Section 40 of the Act of 1858, my opinion is that it would, at any rate at present, be premature to do so, especially as I think that any such proposed legislation would be involved in considerable difficulty. I have personally, on the instruction of other distinguished medical bodies, drawn or attempted to draw more than one clause for the amendment of the law as enacted in Section 40 of the Act of 1858, but I have found it a very difficult task. Any such clause would, I think, lead to very considerable discussion in Parliament of that and other provisions of the Medical Acts which might have the effect of ultimately weakening some extremely beneficial provisions of these statutes. I cannot agree that there are such difficulties in the way of securing a conviction under Section 40 as makes it necessary that there should be an attempt at further legislation. I think that in a case presented to the courts before a strong and competent tribunal there is no difficulty in securing a conviction. Speaking from my experience of the cases in which I have personally been engaged as counsel, no serious difficulty has been found in securing a conviction in a case in which the charge is carefully framed so as to bring it within the provisions of Section 40, and also in which the evidence is careful and abundant, and also, I am bound to add, in which one has a sufficiently strong tribunal. The tribunal to whom one has to go is a justice of the peace; and I am not wanting in respect to that body if I say that the quality of justice administered by justices of the peace all over the country varies considerably. Now, the misfortune of these two cases in my opinion is that they will afford a handle to weak magistrates to dismiss charges made under Section 40, and so far as one of the cases was a decision that a person might assume the title of M.D. with U.S.A. attached to it with impunity it was a very unfortunate decision. But, on the other hand, one may contrast with these decisions the decision in the case of Steele against Ormsby, where a person signed himself M.D. with Bc (signifying Botanic) attached to it, and no difficulty was experienced in obtaining a conviction. In Regina *v.* Baker, where a person with an American degree signed a certificate M.D., no difficulty was found in obtaining a conviction and the full penalty was imposed; and in the case of Ferdinand, where a man assumed the title of M.D. U.S.A., where there was abundant evidence that the persons to whom he assumed it believed that he was a duly qualified person and that the certificates which he gave were effective certificates of a qualified medical man, there again no difficulty was experienced in obtaining a conviction and the fullest possible penalty. In addition to those cases no difficulty was experienced in obtaining convictions in some cases in which the practitioners had been removed from the Register and had had their qualifications taken away by the bodies which had granted them, and who had yet continued to assume the titles granted by those bodies. In one of those cases it had been contended that it was not illegal for the practitioner to assume a title which had been originally granted to him, although it had been taken away, but that contention was dismissed by a very strong magistrate, and a conviction was secured. The one case which is doubtful and is left doubtful by these decisions, and upon which one of the judges expressed his opinion that a decision ought, if possible, to be obtained, was the case of a person who is struck off the Register, but whose registrable qualification is not taken away by the qualifying body which granted it, and who continues nevertheless to practise under that qualification. There is a strong dictum of Lord Coleridge in the case of the Queen *v.* Baker that a person who so practises is practising in circumstances which imply falsely that he is registered in respect of the qualification which he assumes. But suffice it to say that the cases of Frickhart and Bridgewater did not present that particular point of law in a form in which it could be conveniently decided by the High Court. I venture to think that the breakdown of these two cases was a breakdown mainly due to the way in which the magistrate dealt with it and is by no means such a serious matter as is thought. On the other hand, I venture to think that any proposition to amend legislation would be embarking upon a very troublesome and risky adventure, and my opinion is that there is no present necessity for it and that it is premature to invoke the assistance of Parliament. I think that any amendment to Section 40 should be considered with reference to rather larger questions and possibly with a view to including a larger number of false assumptions of titles than is included in that section, but merely to propose legislation for the purpose of more easily securing conviction under that section is, I venture to suggest to the Council, inexpedient.

The Apothecaries' Hall of Ireland: Decision of the Council.

The Council then resumed the consideration of the application of the Apothecaries' Hall of Ireland for the appointment by the Council of assistant examiners in medicine and surgery. On Wednesday Mr. Tichborne

Digitized by Google

moved that the application be acceded to, but he withdrew the motion in favour of one by Sir William Turner to this effect—viz.:

"That the Council defers for the present the expression of an opinion on the application of the Apothecaries' Hall of Ireland for the appointment of assistant examiners in medicine and surgery, and directs communications to be made to the Apothecaries' Hall and to the Royal College of Surgeons in Ireland with the view to their reconsideration of their respective positions, so that such a combination may be effected between them as may ensure that an efficient standard of examination shall be maintained by the General Board of Examiners which will be satisfactory to the Medical Council."

Mr. MILLER (clerk) read a short statement on the legal aspect of the question which had been prepared by Mr. Muir Mackenzie. In this the Council were reminded that the Privy Council had expressed no opinion upon the appeal of the Apothecaries' Hall. During the argument their lordships intimated that in their view the case, so far as they had heard it, was one which might advantageously be reconsidered by the General Medical Council on a further application to be made by the Hall in terms different from those of the application which was refused, and the further hearing of the case was accordingly postponed to enable the Hall to submit an application in the form suggested by their lordships. The suggestion that the application of the Hall should be again made and considered came from members of the tribunal, which was not only the highest in the kingdom, but was also the tribunal of appeal from the decisions of the General Medical Council constituted by Act of Parliament. The suggestions which had been made by the Lords of the Council therefore not only deserve most earnest consideration, but in his opinion afforded ample ground for the General Medical Council to review and alter if they saw fit their formal decision. If the General Medical Council thought fit to take this course the necessity of obtaining a decision on the point of law which was raised by the appeal of the Privy Council and the danger of anything amounting to a difference between the General Medical Council and the Privy Council would be avoided. The General Medical Council could not reasonably be found fault with for carrying out the spirit of an instruction which came from authorities of the highest eminence all of them desirous that the authority of the General Medical Council's decisions should not be weakened.

Dr. CHURCH said he had given this matter some attention and he found that as long ago as 1868 their Visitors expressed dissatisfaction with this examination, and again in 1875, and again in 1882. Since 1886 they had reported the examination as insufficient each time they had visited it. No sooner had the Conjoint Board of the Apothecaries' Hall and the Royal College of Surgeons in Ireland been established than they began to accept men for examination who had not got certificates of attendance on all the subjects required. When the attention of this Council was drawn to the matter, the body said at once, "Oh, we will require certificates in them all, just as you wish." He heard Mr. Tichborne say that no Licentiate of the Apothecaries' Hall had ever been found guilty of unprofessional conduct or, as the phrase went, of infamous conduct in a professional respect. When he heard that he thought this body was warmly to be congratulated, but, unfortunately, the statement was not accurate. If Mr. Tichborne would look down the erasure list of this Council he would find that in 1880 a Licentiate of the Apothecaries' Hall of Ireland had his name erased from the Medical Register for infamous conduct in a professional respect.

Mr. MUIR MACKENZIE, replying to a question put to him by Dr. Church, said that if the Council were to refuse to entertain the further application, then the appeal of the Apothecaries' Hall from the prior refusal would come on again before the Privy Council for consideration, and that would involve a decision of the point of law whether the refusal of the Council in such circumstances was absolute. The Privy Council had suggested to the one side to apply again and to the other to consider that application.

Dr. MACALISTER moved as an amendment to Sir William Turner's motion:—

"That the President be requested to inform the Lord President of the Privy Council as follows:—(*a*) That the General Medical Council has received from the Apothecaries' Hall of Ireland an application for the appointment of Assistant Examiners in Medicine and Surgery for the purpose of enabling that body to hold an independent qualifying Examination in Medicine, Surgery, and Midwifery. (*b*) That it appears to the General Medical Council that the appointment of such Assistant Examiners would not enable the Council in this particular case to fulfil its statutory duty of maintaining the standard of efficiency required in examinations which qualify for registration in the Medical Register. (*c*) That the General Medical Council has accordingly felt it to be its duty to decline to accede to the application."

He asked the Council to consider carefully the latter part of Sir William Turner's motion. At the present moment the Conjoint Board of the Apothecaries' Hall and the Royal College of Surgeons in Ireland actually existed; it existed for some five or six years until the remanent candidates had all been examined. The Conjoint Board stood under the ban of this Council. It had been reported as insufficient, and this Council founded their opinion that it was insufficient not only upon the inspection of examinations but also upon the reports of the Examination Committee, saying that the constitution and status of the body in question were not such as to render it capable of maintaining a sufficiently high standard either in education or in examination. It was brought to the notice of the Council that this conjoint body was advertising that certain certificates which were required by all other bodies were not required by them, and that, therefore, students might find it convenient to come up for their examinations in preference to others.

Mr. TICHBORNE: I rise to order. Would Dr. MacAlister name the document to which he refers, because we emphatically deny that we ever issued such a document?

Dr. MACALISTER said he took full responsibility for what he said. The document would be found in sufficient fulness in the proceedings of this Council, and, as a matter of fact, he held in his hand at the present moment a copy of it and would be glad to show it to Mr. Tichborne. The Conjoint Board which they were asked to continue indefinitely was one which had been condemned in matters of education as well as in matters of examination. At the present moment they had reported it to the Privy Council as insufficient. The Privy Council had the discretion upon such a report to order that these examinations should cease to be qualifying. The Privy Council received the report of this Council and said, "Well, we understand this body is moribund, and in these circumstances we do not propose to do anything in the matter," so that the Conjoint Board was reported to the Privy Council and the latter body had given no decision as to whether it should continue to be a qualifying body solely upon the ground that it was moribund and would very soon come to an end. If it was established again then the one cause of the action of the Privy Council would cease, and it would be for the Privy Council to consider the report of this Council that the examination was insufficient. He wished this Council to understand the responsibility they were undertaking if the bodies agreed to reunite. It seemed to him an extremely grave one. Formerly the Examination Committee advised the severance of the two bodies, and now it was proposed that the Council advise their reunion. Whatever irregularities or blunders were made would come upon the back of this Council and not upon that of the Conjoint Board. Supposing they reported again that the Conjoint Board were not doing their duty, what would be the answer of the Privy Council? They would say that the matter was in the hands of this Council, that they were responsible for the Conjoint Board, and must see it through. In this way the Council would be paralysed in the discharge of their duty. A good deal had been made of the cry that they were disfranchising a body by a side wind, but such was not the case, and a little inquiry would show that no body could be disfranchised without a most elaborate process.

Dr. BATTY TUKE seconded the amendment.

Mr. TICHBORNE said he desired to correct an error made by Dr. MacAlister. That gentleman said that the licensing body had issued certain regulations to which he took great exception and he introduced a document. That document the licensing body had nothing at all to say about. It was the advertisement of the school belonging to the Royal College of Surgeons in Ireland. It was issued in 1893 and two or three days afterwards, at the next meeting of the Conjoint Committee of the two bodies, they drew the attention of the Council of the Royal College of Surgeons in Ireland to it and requested it to be withdrawn. But let the Council clearly understand that the advertisement did not emanate from the Conjoint Board and that they had nothing whatever to do with it.

Dr. ATTHILL said it was with great reluctance that he took part in this debate, but he could not remain silent, for he regarded Sir William Turner's motion as a retrograde movement which would have disastrous consequences, not only on the school of medicine in Ireland, but on the whole profession. He could understand members of the Council voting to give examiners to the Apothecaries' Hall for various reasons, but he could not understand them voting to go

Digitized by Google

back upon a system and re-instate a body which had been so emphatically condemned. Such a course would, in his opinion, be discreditable to this Council. They were not a very popular body as it was. The medical public was disappointed with them, and he thought they should take care to do nothing to lower themselves in the respect of the profession. When the Act of 1886 was passed and the Apothecaries' Hall of Ireland was constituted a qualifying body he considered it his duty to test the feeling of the Royal College of Physicians of Ireland as to whether the Hall should be admitted as a third party into a combination. He used every effort to induce the College to favour the conjunction, but out of the forty Fellows he only got four to vote with him. At the time he thought a conjunction was possible; now he knew it to be impossible. He could not advocate it now for the simple reason that in the interval the status of the Apothecaries' Hall of Ireland instead of being heightened had been materially injured and lowered by the revelations of the last few years. In the recent election of a direct representative one of the candidates was an avowed advocate of the Apothecaries' Hall of Ireland and went forward entirely as such, and he received only about 400 votes out of 2000. That showed the opinion of the medical profession in Ireland on the subject. There had been a special meeting of the Royal College of Physicians of Ireland since he came to London, a meeting largely attended, at which the opinion was unanimously expressed that they could not comply with the request of the Royal College of Surgeons in Ireland to confer with them as to the expediency of creating a tripartite examination. The Council might take that as final, at any rate for this generation of the Royal College of Physicians. He could not help thinking that if the Council gave way in this matter they would be sacrificing their self-respect, and they certainly would not be improving their position in the estimation of the medical profession.

Dr. BATTY TUKE asked Sir Philip Smyly, the representative of the Royal College of Surgeons in Ireland, and Mr. William Thomson, its President, whether there was any chance of a combination being come to between their College and the Apothecaries' Hall of Ireland during the next six months.

Sir PHILIP SMYLY replied that the question had not been before the Council of the College, but personally he did not think they were likely to combine again with the Apothecaries' Hall of Ireland.

Mr. WILLIAM THOMSON said that from what he knew of the views of the Council of the College he had no doubt that nothing whatever would be done with regard to carrying out the suggestion for another combination with the Apothecaries' Hall of Ireland. It would be considered if it came before them, but that the Royal College of Surgeons in Ireland would join again with the Apothecaries' Hall of Ireland he did not believe to be in the least degree possible.

Dr. BATTY TUKE asked whether after these declarations it was worth while going on with Sir William Turner's motion.

Sir JOHN BANKS said he had no desire to follow Dr. Atthill into all his observations, but there was one point to which he desired to call attention. Dr. Atthill spoke of his regard for the honour of the profession in Ireland. He thought he (Sir John Banks) could claim that he had as lively an interest in the honour of the profession in Ireland as Dr. Atthill or anybody else, and he wished to say that he had known for many years members of the Apothecaries' Hall of Ireland, highly respectable gentlemen, general practitioners, men of the highest character, and he believed, as he said on Wednesday, that the Apothecaries' Hall of Ireland would carry out any promise they made. One of the arguments used for opposing the Apothecaries' Hall of Ireland was that they had neither a school nor a museum, but he should like to know whether all the other bodies represented on this Council had schools and museums. He had the greatest pleasure in supporting the motion of Sir William Turner, which he believed offered a way out of the difficulty.

Sir WILLIAM TURNER said the discussion had not been upon Dr. MacAlister's amendment. Nobody, so far as he was aware, had had a word to say in regard to it, and all the support the seconder had given it was by putting two questions. The discussion had really been on his (Sir William Turner's) motion. He could not withdraw the motion. It was impossible for him to withdraw it. Mr. Tichborne had withdrawn the original motion debated on the previous Wednesday on the understanding that his (Sir William Turner's) motion should go to the vote. He therefore as a man of honour, and in justice to Mr. Tichborne, must adhere to his motion. When the Council were voting he hoped they would bear that in mind, for the motion would be pressed to the vote even if Dr. MacAlister's amendment was not carried. He did not think Dr. MacAlister had quite fully represented the motion in his criticism of it. Dr. MacAlister had spoken of it merely as if it proposed a restoration of the Conjoint Board on the old basis. He had expressly pointed out that he had something more in his mind than a restoration on the old basis. What, in fact, he had contended for was that the restoration should be on the basis of both bodies taking the responsibility of the entire examinations and not that each body should regard itself as responsible only for that part of the examination which it more immediately represented. If a board were formed more on the basis of the London or the Scottish Conjoint Board there would be a much more effective control of the examinations than there had been up to this time. That was what he contended for when he proposed the motion and what he wished the Council to think was in his mind.

Sir WALTER FOSTER pointed out that when Mr. Tichborne withdrew the original motion in favour of Sir William Turner's proposal there was an honourable understanding that he did so without prejudice to his right to move an amendment afterwards. If the Council adopted Dr. MacAlister's amendment they would carry a motion in direct antagonism to Mr. Tichborne's motion. The highest tribunal in the land with the greatest consideration for this Council and with the kindest intentions had given the Council a very broad hint of what it should do, and he hoped the Council would hesitate before it voted against Sir William Turner's very judicious motion, which he thought would get the Council out of a difficulty which might otherwise become a difficulty that would hang about their necks for many succeeding sessions.

The PRESIDENT called attention to Section *b* of the amendment, which he characterised as the most self-condemnatory of the Council that had ever been put before it. He said the reply to it would be this: "If you cannot maintain efficiency we must do it for you."

Dr. MACALISTER thought the Privy Council placed it within their discretion to answer the question, Is it consistent with your duty or inconsistent to start a new examining board, and if you do, do you think it will work? Their answer to it, and he considered it was an answer that would be received by the Privy Council with respect, was that they did not consistent with their duty, and that if set up the board would not work. After the Privy Council had received their answer they might tell them to set up the board.

The Council divided on the amendment, which was rejected by 13 votes to 12, four members declining to vote. Sir William Turner's motion was then put, when it was found there was an equality of votes, 13 being for the motion and 13 against it, three members, including the President, declining to vote. The President being called upon to give a casting vote gave it in favour of the motion, which thereupon became the finding of the Council.

DIVISION LIST.

Vote on Dr. MacAlister's Amendment.

Against, 13.

The President.	Dr. Gairdner.	Sir Philip Smyly.
Mr. Wheelhouse.	Sir John Banks.	Sir Walter Foster.
Sir William Turner.	Dr. Glover.	Dr. Philipson.
Dr. Heron Watson.	Mr. Tichborne.	Dr. Bruce.
Dr. McVail.		

For, 12.

Mr. Bryant.	Dr. Thorne Thorne.	Dr. Leech.
Sir Dyce Duckworth.	Mr. Thomson.	Dr. MacAlister.
Dr. Church.	Dr. Fraser.	Dr. Tuke.
Dr. Atthill.	Dr. Cameron.	Dr. Wm. Moore.

Did not vote, 4.

Dr. Pettigrew.	Mr. Teale.	Mr. Carter.
Sir Wm. Roberts.		

Absent, 1.

Dr. Haughton.

Vote on Sir W. Turner's Motion.

For, 13.

Mr. Wheelhouse.	Sir John Banks.	Sir Philip C. Smyly.
Sir William Turner.	Mr. Teale.	Sir Walter Foster.
Dr. Heron Watson.	Dr. Glover.	Dr. Philipson.
Dr. McVail.	Mr. Tichborne.	Dr. Bruce.
Dr. Gairdner.

The President.	Dr. Pettigrew.	Dr. Church.

Absent, 1.

Dr. Haughton.

The number for and against the motion being equal, the PRESIDENT gave his casting vote in favour of the motion.

The Case of Mr. R. M. Theobald.

The REGISTRAR (Mr. Miller) read a letter from Mr. R. M. Theobald applying for a rehearing of his case.

Mr. BRYANT said that the Royal College of Surgeons of England had received repeated applications from Mr. Theobald for the restoration of his name to their Register, but up to the present time they had refused compliance, not so much in the way of punishment to the man as in that of warning to others against following such courses as had led to the expungement of Mr. Theobald's name. He hoped the Council would continue to refuse restoration so long as the Royal College of Surgeons continued to refuse.

Mr. FARRER, the solicitor, pointed out that Mr. Theobald wished to be re-heard.

Dr. MACALISTER said that the case had been fully gone into in Mr. Theobald's presence during last November session, and there should be a motion from the chair that there was no cause for re-opening the case.

Dr. GLOVER said he would like to know clearly whether their hands were or were not tied. Were they able to register Mr. Theobald before the Royal College of Surgeons of England had restored his diploma?

Mr. FARRER: You cannot put a man upon the Register who has not got a registrable qualification.

Mr. BRUDENELL CARTER mentioned that Mr. Theobald had lost his diploma before the Council took his name off the Medical Register.

The PRESIDENT moved: "That Mr. Theobald be informed that in the opinion of the Council no cause has been shown for the re-opening of his case."

This proposal was unanimously agreed to.

Withdrawal of Qualification.

A communication from Mr. R. A. Woods, secretary of the Council of the Royal College of Surgeons in Ireland, intimating that the name of Mr. Samuel Frederick Murphy, whose name was removed from the Medical Register by the General Medical Council in June last, had been removed from the list of Licentiates of the College, was, on the motion of Mr. WHEELHOUSE, received by the Council and entered on their minutes.

Registration Changes.

Dr. HERON WATSON moved that the Council receive from the Executive Committee and adopt the following suggested standing order for the carrying out of the Council's resolution of last session:—

"11. In accordance with the provisions of Section XXV. of the Medical Act (1858) the Branch Registrars shall, with all convenient speed, send to the General Registrar and such other Registrars a certified copy of all the changes so made in the Branch Register; and the General Registrar shall forthwith cause such changes in the Branch Registers to be made in the General Register, and he shall intimate all changes made in the General Register to each Branch Registrar, so as to secure that in the office of each Branch Registrar an authoritative copy of the General Register shall be available for consultation and reference."

Mr. WHEELHOUSE seconded, and the motion was agreed to.

Documents in Penal Cases.

Dr. CHURCH moved an amendment to the standing orders so as to secure that, along with the business programme for the session, which is sent to members three clear days before the session begins, there should also be sent to them copies of the documents and evidence in the penal cases to be brought up during the session.

After some discussion, in which Mr. MUIR MACKENZIE thought the course suggested could be adopted without inconvenience, the motion, which was seconded by Mr. WHEELHOUSE and supported by Dr. LEECH, was agreed to.

Society of Apothecaries of London.

On the motion of Mr. BRUDENELL CARTER, seconded by Mr. BRYANT, it was agreed—

"That Mr. C. P. Lockwood, F.R.C.S., L.S.A., assistant surgeon to St. Bartholomew's Hospital, be appointed an Assistant Examiner in Surgery to the Society of Apothecaries for a term of five years, in the room of Mr. Arbuthnot Lane, who is retiring from office by rotation."

Mr. BRYANT remarked that he knew Mr. Lockwood very well as a very excellent surgeon and a good examiner.

Penal Powers of Qualifying Authorities.

Mr. BRYANT, on behalf of the Executive Committee, presented a report on the disciplinary or penal powers of the qualifying medical authorities. He said he did not propose to read the whole report. The pith of it was contained in the following passages:—

"Information has been forwarded by all the bodies, and an analysis of the replies thus furnished shows that the following Universities have no, or only insufficient, disciplinary powers: The four Scottish Universities; the University of Durham has power only to remove a name from the University Calendar, but cannot take away the degree; the University of Cambridge; the Victoria University, which has no powers; and the Royal University of Ireland (formerly Queen's University), which has no powers. With regard to the several Colleges it is stated that they have sufficient disciplinary powers, that the Apothecaries' Society of London can strike off the list of Licentiates any name erased from the Medical Register, but cannot cancel the diploma, and that the Apothecaries' Hall, Dublin, can only recover fines in the superior courts. It would from this summary appear that there are six universities which do not possess any disciplinary powers, and that there are in addition two universities which possess only partial or limited disciplinary powers over their graduates. The result is this, that however gross the misconduct of a graduate may be, whether as a convicted felon or declared by the General Medical Council guilty of infamous conduct in a professional respect, for which his name has been removed from the Medical Register, he still retains the degree and the title conferred upon him by any one of these universities. Such a state or condition of matters must cause very considerable regret to the authorities of the university which has conferred the degree, and which it has no power to cancel. The association of their names with such black sheep amongst them must also cause much regret to be felt by the graduates and must lead them to feel how desirable it is that the authorities of the University should obtain powers to take away degrees which are thus discredited. Notwithstanding their removal from the Register graduates are now in practice under the title which they have obtained, greatly to the injury and perplexity of the public. On reference to the list of University graduates who have been declared guilty by the General Medical Council of infamous conduct it is found in regard to the Scottish universities that four such graduates held the degree of the University of Edinburgh, four that of the University of Glasgow, one that of the University of St. Andrews, and two that of the University of Aberdeen. The General Medical Council may entertain a well-founded conviction that when this state of matters is brought to the notice of the Scottish Universities they will use all the powers they possess or can acquire to remedy such a discreditable state of matters. The Committee recommend that the Scottish Universities Commission now sitting, which regulates the proceedings of Scottish universities, should be approached with the object of obtaining their assistance in strengthening the disciplinary powers of the Scottish universities in these respects. The Council may, therefore, think fit, in addition to bringing the subject before the several universities, to submit this report to the Statutory Commission direct. With reference to the English universities, two do not possess complete disciplinary powers, and one—the Victoria University—possesses none at all. One of the Irish universities—the Royal University of Ireland—likewise possesses no disciplinary powers. Of the graduates of those universities whose names have been erased from the Medical Register, one held the degree of the University of Cambridge; one held the degree of the University of Durham (his name has been erased from the list of graduates, but he cannot be deprived of his degree); and two held the degree of the Queen's University of Ireland. There can be but very little doubt that by proper representation to the Privy Council means would be afforded to these universities, by the insertion of a clause in their respective charters, for remedying this objectionable state of matters. With that view the Committee recommend that a copy of this report, if adopted by the Council, be forwarded to the Privy Council asking special attention to the remedying of this grievance."

Mr. BRYANT also read the following appendix to the report:—

"4, Temple-gardens, E.C., May 27th, 1896.

"DEAR SIR RICHARD QUAIN,—With reference to the report of the committee on the disciplinary or penal powers of the qualifying medical authorities and my letter of yesterday, the questions which it raises derive increased importance from the cases recently tried in the Courts of Justice, in which practitioners who have been struck off the Register have continued to practise under the titles of which the qualifying bodies had no power to deprive them; and the question has been raised whether such a practitioner can be successfully charged with falsely assuming a title which implies that he is registered.

"The judges, and particularly Mr. Justice Collins, have stated from the Bench that in their opinion the question is one of great public importance, on which the law, as laid down in the decisions of the Courts, is in an uncertain and unsatisfactory state.

"It will thus be of the greatest public benefit if the charters of the bodies which have insufficient penal powers can be amended as suggested in the report.

"It seems to me that in each case the formal procedure would be for the university or other body to petition her Majesty in Council for amendment of its charter.—Believe me, yours very truly,

"M. MUIR MACKENZIE."

On the motion for the adoption of the report, which was moved by Mr. BRYANT and seconded by Mr. WHEELHOUSE,

Dr. GLOVER, as the proposer of the resolution which referred the matter dealt with to the executive committee, expressed satisfaction at the admirable report which had

Digitized by Google

been presented. He was sure all the qualifying authorities, and particularly the universities, would feel grateful for it. The universities had shown a creditable desire to have more power than they had at present and he hoped they would get it.

Sir JOHN BANKS knew that the two Irish universities wished to have more power of the kind in question.

Dr. MACALISTER said that it was only a short time since the Queen in Council had approved of the extension of penal powers to the University of Cambridge. They, however, had sought for more than had been granted.

Dr. LEECH expressed his intention to urge upon the authorities of the Victorian University to go in the direction the Council desired.

Dr. PHILIPSON felt certain that if the recommendations of the committee were given effect by any of the bodies every endeavour would be made on the part of the governing body of the University of Durham to obtain the necessary powers by an amendment of their charter.

Dr. HERON WATSON said there could be no objection to the Council approaching the Scottish Universities Commission in regard to this matter; but he begged to state that Sir William Turner had already made a long statement to them on the subject, with the only result that he was informed the Act gave them no powers to take up such a subject or put forth any document in regard to it.

After further remarks it was agreed: "That this report be adopted and the recommendations therein contained be carried into effect by forwarding copy of the report to (1) the universities and other boards concerned, (2) the Scottish universities, and (3) the Privy Council."

Dental Registration.

The Council considered the following communication from the Privy Council in regard to an application from Mr. Alfred Perkin Merrill, 52, Collins-street, Melbourne, Victoria, for registration by the General Medical Council as a dentist, viz.:—

"76,556. "Whitehall, Feb. 21st. 1896.

"SIR,—I am directed by the Lords of the Council to transmit to you the accompanying copy of a petition of Mr. Alfred Perkin Merrill, a dentist practising at Melbourne, in the colony of Victoria, appealing to the Privy Council against the decision of the General Council of Medical Education and Registration of the United Kingdom not to place his name on the Dentists' Register, together with a copy of an affidavit sworn by Mr. Merrill in regard to his qualifications as a dentist, and I am to request that, in laying the same before the General Medical Council, you will move that body to furnish their lordships with any observations they may desire to offer upon the appeal of Mr. Merrill. "I am, Sir, your obedient servant,

"C. L. PEEL.

"The Registrar of the General Medical Council."

The REGISTRAR read the following observations on the case by the Council's legal adviser:—

"1. The 8th Section of the Dentists Act, 1878, provides that a person who is not domiciled in the United Kingdom and shows that he holds some recognised certificate (as defined in the Act) granted in a British possession and that he is of good character is to be entitled without examination in the United Kingdom to be registered as a colonial dentist. 2. The 9th Section of the same Act provides that where a person who is not a British subject shows that he obtained some recognised certificate (as defined in the Act) granted in a foreign country, and that he is of good character and continues to hold such certificate, is to be entitled without examination in the United Kingdom to be registered as a foreign dentist in the Dentists' Register. 3. By Section 10 of the Act the certificate granted in a British possession or in a foreign country which is to be deemed such a recognised certificate as is required for the purposes of registration is to be such certificate, diploma, membership, degree, &c., or other title, status, or document as may be recognised for the time being by the General Council, as entitling the holder to practise dentistry or dental surgery. The following facts in relation to the application of Mr. Merrill for registration are material for the purposes of inquiring whether he satisfies the foregoing statutory conditions. 4. In the year 1862 and 1864 Mr. Merrill, being at the time an American citizen, practised dentistry in Canada and in Barbadoes. 5. In 1886 Mr. Merrill obtained from the Philadelphia Dental College his diploma of D.D.S., and subsequently for some years practised as a dentist in New York. 6. In the month of April, 1890, Mr. Merrill was registered in the Dentists' Register of the Colony of Victoria, and at the same date, which is not stated in the papers, Mr. Merrill became a naturalised British subject in Victoria. 7. As regards the American diploma held by Mr. Merrill in the year 1879, the General Council caused very full inquiries to be made in reference to the courses of study and examinations required by several of the foreign and colonial dental colleges and institutions with the view of ascertaining whether the certificates or diplomas of those institutions furnished sufficient guarantees of the possession of the requisite knowledge and skill for the efficient practice of dentistry; and amongst the diplomas or certificates which were the subject of inquiry were those granted by the Dental College of Philadelphia. The General Council ascertained that in this institution, as in several others, there was no preliminary examination, that two years only of professional study were required, and that the examination in each was conducted solely by the teachers and officers of the institution. The General Council, therefore, having regard to the requirements which are necessary for diplomas in dentistry in the United Kingdom, which comprise a preliminary examination and four years of professional study, felt unable to recognise the certificate of the Philadelphia Dental College as one which ought to entitle the holder to registration as a Foreign Dentist in the *Dentists' Register*. 8. As regards the registration of Mr. Merrill in the *Dentists' Register* of Victoria, the General Council have not hitherto been able to recognise that a person who is so registered, but who does not possess any colonial diploma or licence, is the holder of a certificate which furnishes sufficient guarantees of the possession of the requisite knowledge and skill for the efficient practice of dentistry or dental surgery. 9. Mr. Merrill apparently is applying for registration as a colonial dentist and not as a foreign dentist. The possession of the foreign diploma, even if it were recognised, would not entitle Mr. Merrill to be registered under Section 8 of the Act as a colonial dentist. 10. The only qualification therefore which Mr. Merrill possesses, on which he can found an application for registration as a colonial dentist, is the fact that he is registered in the *Register* of Victoria. But, as already stated, the General Council have not been able to and do not recognise registration in this Colonial Register as of itself entitling an applicant to be registered under Sections 8 and 10 of the Act."

Sir WILLIAM TURNER moved "That the observations prepared by the Council's legal adviser on the petition of Mr. Alfred Perkin Merrill be adopted by the Council and forwarded to H.M. Privy Council as the answer of the Medical Council to the appeal."

Mr. WHEELHOUSE seconded, and the motion was agreed to.

Practical Midwifery.

Dr. BATTY TUKE read a report by the Education Committee on the recommendations of the Council in respect of practical midwifery. This set forth in detail the regulations of the various licensing bodies on the subject, and went on to show that as these regulations afforded but meagre information bearing on the point at issue the committee had directed the Registrar to issue a circular in the following terms:—

"With reference to a subject now under investigation by the Medical Council in regard to the subject of practical midwifery and the Council's recommendation that every student should be required either to attend for three months the in-door practice of a lying-in hospital or to have been present at not less than twelve labours, at least three of which he should have conducted personally under the direct supervision of a registered practitioner, I am directed to request that you will state, for the information of the Council, what method is adopted by your body to ensure that the requisite number of labours are so personally conducted under the direct supervision of a registered practitioner and by whom the certificate of such attendance is signed."

The report went on:—

"At this point the question has to be determined what meaning is to be attached to the words 'direct supervision' contained in the recommendation. In the opinion of the committee they ought to imply that the labours had been conducted in the presence of the practitioner, who could accordingly give actual clinical instruction on the three cases referred to in the recommendation during all the stages, and who should further attend with the student during the whole puerperal period, and give instruction in the after-treatment of mother and child. If this interpretation of the recommendation be accepted it is evident from the general tenour of the replies of the bodies that little assurance is given that the recommendation is acted on in this sense. For the most part the certificate of any registered practitioner is accepted, and reliance is placed on the good faith of the certifier. But the practitioner has nothing to guide him as to the amount and kind of supervision he is expected to certify to. This may range between the mere introduction of the student to a case and full attendance throughout the whole puerperium. In order to secure attention to these special points and to ensure as far as possible uniformity of practice the committee recommend that the Council should issue to the licensing bodies a form of certificate to be presented by candidates setting forth the number of cases conducted under supervision, the number at which the practitioner has been present, and that the student attended the cases throughout the puerperal period. The concluding clause of the reference is general, asking the committee to report on any modification of the recommendation they may think to be desirable. Judging from previous motions which have been before the Council, and from the fact that the petition of the Council of the British Medical Association, advocating an increase of the number of cases to be attended by the student, was referred to the committee at the same time, it may be presumed that the Council desired a report as to whether, in the opinion of the committee, any extension of the existing recommendation as regards numbers of cases is called for. The questions involved in the consideration of this subject are complex. They have been debated in the Council on several occasions, and have given rise to the expression of very diverse opinions. The Council has no evidence before it that education in respect of midwifery is deficient in Great Britain and Ireland. In no single instance have the inspectors of examinations reported 'insufficiency' as regards midwifery; nor is the committee aware that any representation to that effect has come from the outside public. The petition of the Council of the British Medical Association assigns no reasons in support of its opinion that the existing recommendation is not satisfactory. The advocates of extension maintain that the standard of practical teaching in midwifery is inferior to that required by the licensing boards in the case of medicine and surgery; that the requirements of the Council fall short of those of other countries; and that it is impossible for the student to gain any adequate amount of experience from the observation of twelve cases. It has been argued, on the other hand, that as the main object of clinical midwifery is to illustrate the process of normal labour and the general management of lying-in women, which can be attained by the observation of a limited number of cases, the demand for more than now prescribed is unnecessary; that were

Digitized by Google

ıe number increased to thirty, or even more, no certainty of the udent seeing abnormal cases could be ensured; that he must, as gards midwifery, gain experience after qualifying in the same manner he does in respect of medicine and surgery; and that too much of his me would be occupied by the study of midwifery to the prejudice of s work in other respects. The committee have taken all these guments into account. Without criticising them separately, but vertheless giving each due weight, they consider that a mean may arrived at. The committee hold that the alternative conditions, ther of three months' attendance on the practice of a maternity hosal or of being present at a given number of cases, a proportion of which all have been conducted under the supervision of a registered practiıner, are disproportionate. They think that systematic instruction is uch more likely to be obtained by the adoption of the former alternave, and that it ensures the actual presence of practitioners fitted to teach actical midwifery. In this connexion it will be observed that the ıncil takes no note of the number of cases under observation during ıe three months, but depends on the constant association of the udent with the general work of the hospital. The efficiency of inical teaching in any department of medicine or surgery is not aranteed so much by the number of cases submitted to the student by the assiduity of the teacher and the conditions under which struction is imparted. There is not, however, sufficient accommodaon in the lying-in and maternity hospitals of this country to provide r 3000 students. The licensing authorities, accordingly, are compelled utilise the opportunities afforded for practical midwifery teaching by ıe general practitioner. It may be difficult in general practice to ford the same continuity and thoroughness of teaching obtainle in maternity hospitals; but the committee think that ıe nearest approximation may be reached by the adoption the certificate suggested in the first part of the report. its conditions are enforced the student should be certain receiving adequate clinical instruction on five cases in the presence the practitioner before he proceeds to attend labours 'under supersion.' The question remains. How many cases should be attended nder supervision'?—which term implies that the practitioner's preıce is not required during the whole course of the labour, unless mplications arise. In coming to a decision on this matter the comittee are much influenced by the fact that the regulations of a large ajority of the licensing authorities are framed in excess of the ıncil's recommendation. Five demand production of evidence of tendance on thirty cases, six on twenty, and four on twelve. In any instances an increase of the number of cases was made when ıe five years' curriculum came into force. It is thus evidently the inion of the majority of the bodies that with an extra year of study, hich the Council desires should be mainly devoted to clinical work, fficient time is at the command of the student for a somewhat nger course of practical midwifery than that originally prescribed y the Council. Were it for this reason only the Committee is repared to recommend the Council to express a strong opinion that ıe minimum number of cases to be attended by candidates for licences ıould be raised to twenty. The Committee believe that if the conitions of the certificate they advise to be issued be faithfully complied ith—if each student attends five cases in the presence of an officer of maternity hospital or of a registered practitioner, conducts fifteen ıses, "under supervision," and observes all the cases during the whole uerperal period, the standard of practical teaching of Midwifery will ave been placed more nearly on an equal footing with that of Medine and Surgery. One circumstance stands in the way of the Comittee recommending the Council to at once pass a recommendation ıbodying this change in the requirement. The bodies whose regulaons provide for attendance on the smallest number of cases are the cottish Universities and the Conjoint Board in Scotland. The regulaons of the Universities now in force were framed by the Commission cting under the powers given by the Universities (Scotland) Act, 1889, ıd were issued in 1898. The Commissioners, in framing the Regulations ı respect of Practical Midwifery, adopted the recommendation of the ouncil, re-affirmed in 1893 and 1891. They further enacted that six ıses instead of three should be conducted personally by the student. he Ordinance containing the regulation has been approved by Her ajesty in Council, after having been laid before both Houses of arliament and has now the force of an Act. No machinery appears exist for its modification so long as the Commission is in existence. rovision, however, is made by which the senates may increase the umber of cases, with the sanction of the University Courts; but they annot assume this power until after the expiry of the Commission. t is manifest, therefore, that under existing circumstances it would e impracticable to give effect to a recommendation insisting on ıcreased attendance by students on practical midwifery in Scotınd. The Committee accordingly recommend the Council to xpress its opinion that twenty should be the minimum number f cases of labour to be attended by candidates for licences practise, five of them to be conducted under the direct supervision f a registered practitioner, and that this opinion should be forwarded the Scottish universities with a request that the senates should take into their serious consideration as soon as they acquire the power to lter or modify the existing ordinances. Moreover, the committee esire to state that in their opinion the instruction of the student in ractical midwifery should not end with the completion of labour, but hould be continued during the whole puerperal period, and that the ouncil should receive assurance that this important part of obstetric ractice is not neglected. The Committee do not deem it necessary that ll the cases should have been conducted in the presence of the certifyıg practitioner, but they think it essential that not less than five hould be certified as having been attended under direct supervision in his sense.

"The Committee recommend the Council to pass the following resoıtions:—1. That in the opinion of the Council each candidate for a cence to practise should produce evidence in the annexed form of aving attended twenty cases of labour, five of which have been conucted throughout under the direct supervision of a registered practiioner. 2. The Council direct that this resolution be forwarded to the uthorities of the Scottish universities, with a request that it be laid efore the various Senates as soon as they are in a position to assume he powers of modifying statutes conferred on them by the Universities Scotland) Act, 1889. 3. The Council direct that Resolution 1 shall be orwarded to the other licensing bodies. 4. That the certificate to be proluced by every candidate before admission to the Final Examination ıe to the following effect:

"....

"I hereby certify that ....
has personally attended [ ] cases of labour under my supervision, of which [ ] were conducted by him in my presence. Also that he attended under my supervision the women in question during the puerperal period.

"....
"Registered Medical Practitioner."

In conclusion Dr. BATTY TUKE said he had nothing to add to the terms of the report. The work had not been at all light. The remit involved a large amount of communications and correspondence, and he though every member of the committee would agree with him that they were very much indebted to one member of the committee, Dr. Glover, for the valuable suggestions and assistance he had given them. The report was a unanimous report, and if the Council would only regard the representative character of it, the statements were to be deemed so much more important. He moved the adoption of the first recommendation.

Dr. GLOVER, in seconding the motion, expressed satisfaction that the subject of practical midwifery had at length been investigated by the Education Committee. They might now make a considerable improvement on their old regulation, of which he had been ashamed and which he felt always to be quite inadequate to meet the circumstances of the case. A requirement of twenty cases would, in his opinion, prove a distinct improvement, as would also be the regulation that there should be instruction of the student during the whole puerperal period. It was quite as important that the young student should see a woman through her recovery as at the time of labour. He regretted the Scotch difficulty, but he hoped it would be within the power of the senates of the universities of Scotland to remedy the defect to which attention was called. While it was with pleasure he seconded the adoption of the recommendation, he wished also to say that he was sure his trouble in the matter had been nothing as compared with that which the chairman, Dr. Tuke, had been put to in getting the report prepared.

Sir WILLIAM TURNER thought that they ought to embody the alternative in the recommendation. If they did not they did not attach more importance to the systematised instruction of the hospital than to the instruction of the general practitioner. Hitherto more value had been attached to the former. Without the hospital alternative the Committee rather seemed to have fallen down and worshipped the idol "twenty cases."

Mr. BRUDENELL CARTER wished to point out what was the actual condition of things in London. He had two sons at St. George's Hospital. One of them got his twenty cases at the lying-in hospital in a week, and he doubted whether he had obtained much systematised instruction in connexion therewith. The other had to reside at St. George's Hospital, and it was five weeks before he got his twenty cases. The stipulation should be not twenty cases, but for a period of time.

Dr. MACALISTER pointed out that it was not the intention to abrogate the alternative.

Sir WILLIAM TURNER: You should set it up.

Dr. MACALISTER: Until the Scotch universities can act we can express an opinion but not make a definite recommendation.

Sir WILLIAM TURNER: Let your resolution embody the two things. Modify it to show that you do not resile from the position.

Dr. BATTY TUKE: We will bring up a modification.

The Council adjourned.

TUESDAY, JUNE 9TH.

The Council held its final meeting, Sir RICHARD QUAIN presiding.

Practical Midwifery.

The discussion on the recommendations of the Education Committee with reference to practical midwifery was at once resumed.

Dr. BATTY TUKE put forward the following motion as a substitute for that which he had moved on the previous day—viz.:

"That it is desirable that in regard to the midwifery practice to be required of candidates for a licence the alternative to three months' attendance on the indoor practice of a lying-in hospital be in future defined as follows:—

"'Or to have been present at not less than twenty labours, at least five of which shall have been conducted throughout under the direct supervision of a registered practitioner.'"

Digitized by Google

This motion, after being seconded by Dr. GLOVER, was accepted by the Council.

Recommendations two and three were also accepted, and Recommendation four was amended to read thus: "That, excepting in the case of candidates presenting certificates of having attended for three months the practice of a lying-in hospital, the certificate to be produced, &c."

Preliminary Examinations.

Dr. BATTY TUKE presented a report by the Education Committee on the preliminary examinations held in the United Kingdom. In this report the committee said they had revised the test of these examinations in view of certain changes that had recently taken place and of certain questions of interpretation that had been raised, and they proposed, with the Council's approval, to issue it in the form they had prepared. The report went on to say:—

"Questions have been raised in reference to the Preliminary Examinations of the Scottish Universities as to the precise application to be given to the following notes appended to the Council's regulations—namely: '(a) The Council will not in future accept any certificate of pass in preliminary examination in general education unless the whole of the subjects included in the preliminary examination required by the Council for Registration of Students of Medicine have been passed at the same time. (b) Provided that a certificate of having passed a University examination required for graduation in arts, or a senior or higher local University examination, or a senior grade Examination of the Intermediate Education Board of Ireland, or the Leaving Certificate Examination (Honours and Higher Grade) of the Scottish Education Department, wherein the specified subjects of general education are included, may be recognised for the purpose of registration.' The committee have understood these notes to indicate that the Council requires, in the case of what may be termed the ordinary preliminary examinations, that the candidate's knowledge of the four prescribed subjects should be such as to enable him to pass in them all at one and the same time. In the case of the more advanced examinations, however, such as those conducted by the universities (or accepted by them as qualifying) for graduation in arts, the Council does not insist that all the subjects shall be taken simultaneously. These examinations being of wider range and higher standard than the others, the policy of the Council has been to encourage candidates for registration to prepare for them, and so to aspire to greater proficiency in the subjects of general education than is implied by the examinations of the ordinary or minimum standard. The committee have reason to think that the provision referred to [Note (b)] has in some measure had the effect contemplated by the Council, and that an increasing number of students qualify for registration by passing one or more of the higher examinations which are thus privileged. The Joint Board of Examiners for the Scottish Universities, who have the control and supervision of the preliminary examinations for admission to the Universities of Edinburgh, Glasgow, Aberdeen, and St. Andrew's, have framed regulations which, in the opinion of the committee, are quite in harmony with the spirit of the Council's requirements. They prescribe that in the case of the preliminary examination for graduation in medicine and surgery, the standard of which appears to be considerably above the minimum recognised by the Council, candidates may at their option take the papers set on the higher standard for the Arts Preliminary in any of the subjects. They further prescribe, by what the committee regard as a legitimate construction of the proviso in Note (b), that the requirement of passing in all the subjects at one time may be relaxed in the case of candidates who have already in one or more of the required subjects obtained the honours or higher grade leaving certificate of the Scotch Education Department. It has been represented to the committee that in view of the acknowledged severity of the preliminary examination the requirement might be further relaxed in favour of candidates who do not take any of the higher standard papers or possess honours or higher grade leaving certificates. In the case of the preliminary examination for graduation in arts conducted by the same board it is provided that all the required subjects (other than those taken on the higher standard) must be passed in at one or not more than two examinations, and this rule is found to work well. The committee are satisfied that, in view of the existing standard, as fixed by the Joint Board, this provision might safely, and also with general advantage, be extended so as to apply to the preliminary examination for graduation in medicine. They are aware that the rules for this examination are at present laid down by ordinance, and cannot be altered until the powers of the Scottish Universities' Commission have ceased. Should, however, the Privy Council hereafter be asked to approve an alteration of the rules in the direction above indicated the committee would take no objection to the change, provided the examination retained its present character and standard. It is accordingly proposed that in the list now issued the condition appended to the preliminary examination of the Scottish Universities shall simply prescribe that the certificate is to include the required subjects. It is assumed that the committee will have due notice of any proposal for an alteration of the existing ordinance which may be submitted to the Privy Council, and they will thus have an opportunity of considering whether or not the proposal is in accordance with the policy of the Council in regard to general education. The committee are, moreover, of opinion that instead of maintaining the proviso in Note (b) it would be clearer if, in the case of every recognised examination, the conditions on which it is accepted were stated in the list. The committee have accordingly adopted this course.

Dr. BATTY TUKE called attention to the fact that the Royal Colleges of Physicians and Surgeons in Ireland still continued their arts examination. The Council had reason to believe that there were ample means in Ireland by which purely educational bodies could conduct this examination, and he took this opportunity of drawing the attention of the representatives of the two bodies to the fact that they stood alone among medical licensing authorities in holding this preliminary examination. He moved that the form in which the Education Committee proposed to issue the revised list of recognised examinations be approved.

Dr. MACALISTER, in seconding the motion, said he hoped when the Royal Colleges of Physicians and Surgeons in Ireland had the matter brought to their notice that they would put an end to the examination. Formerly the Scottish Universities used each to hold their own preliminary examination. Now, however, owing to the action of the Universities Commission, loyally supported by the universities themselves, the whole matter of the preliminary examinations was put in the hands of a Joint Board upon which all the universities were represented. One result had been that the standard of the examination, which used to be somewhat uncertain and somewhat low in some cases, had been raised to a high pitch of excellence, and perhaps there was some ground for the complaint that it had been raised too high. At any rate, it was a significant fact that at a recent examination 60 per cent. of the candidates were plucked.

After some discussion about the College of Preceptors the motion was agreed to.

Dr. MACALISTER moved that the following portion of the report be presented to the Royal Colleges of Physicians and Surgeons in Ireland for their consideration, viz.:—

"Of the examinations in Division II. of the list conducted by medical licensing bodies, which the Council has recommended should be discontinued, all but one have ceased to be held. The recommendation of the Council has thus been carried into effect in England and Scotland. The exceptional examination is that held by the Royal Colleges of Physicians and Surgeons in Ireland. In view of the fact that in addition to those conducted by the Irish Universities three examinations held by the Intermediate Education Board of Ireland are recognised by the Council, the committee reiterate their conviction that it is desirable in the interests of general education that the Royal Colleges should cease to examine in arts. The examinations formerly held by the other licensing bodies have been removed from the list, but certificates granted prior to the date of discontinuance will, in the usual course, still be accepted for registration."

Mr. WILLIAM THOMSON said there were certain difficulties in Ireland with regard to this recommendation of the Council. There were certain university examinations in Dublin and the examinations of the Intermediate Education Board, and, besides, they had their preliminary examinations of the Royal Colleges of Physicians and Surgeons, which, it was true, was the only examination of the kind now surviving. He was not quite sure that this Council was aware of the way in which certain of these examinations were conducted. For instance, the three examinations which were approved, those of the two Universities and the Intermediate Education Board, were held at the same time and were held only once a year. Therefore, they were practically one, and the candidate could only choose one of them. If he should happen to be plucked he must wait for a year before he could make another attempt. So far as the Colleges were concerned, he did not know that they were particularly wedded to this particular examination, but they felt that for the safety and convenience and protection of the student it should exist for the present. For himself he was glad to hear members speaking in tones of dissatisfaction with the whole of this preliminary question. It had seemed to him for many years that this Council had occupied itself perhaps a little too much in elevating and elaborating the professional portions of the curriculum and examinations, and had left absolutely untouched what he regarded as the most important part of the whole educational course—the standard of entrance into the course of professional study. What he felt was that the standard was far too low and that it was subject to all kinds of variations, and he should like to see this question taken in hand by the Education Committee and by the Council and a very considerably higher standard set for the entrance to the profession. He should like very much to see in the great centres of population an entrance examination apart altogether from universities or licensing bodies of any kind—a kind of entrance examination which could be controlled by this Council.

Sir PHILIP SMYLY said he agreed with what Mr. Thomson had said as to leaving alone for the present the examination of the Colleges.

Dr. ATTHILL agreed that it was very desirable that the examination should be done away with. He had urged this upon his own College, but he was assured that in the present state of things it was impossible. The examination of the universities was not sufficient, while that of the Intermediate Education Board was totally unsuitable.

Sir WALTER FOSTER advised the Irish Colleges to make their preliminary examination more stringent and thorough

Digitized by Google

than it was so as to bring it up to a standard that would encourage the General Medical Council to continue it.

Sir JOHN BANKS agreed with Mr. Thomson that the standard at the entrance examination should be raised. If it were raised he thought that would do something to prevent the flooding of the profession with unfit men.

Sir WILLIAM TURNER inquired of the representatives of the Colleges whether the examiners included Fellows of the College?

Dr. ATTHILL replied in the affirmative.

Sir WILLIAM TURNER said there should be no Fellows of the Colleges amongst the examiners, and the first step the two Colleges should take was the reform of their examining board.

The motion of Dr. MACALISTER was then agreed to.

Mr. BRYANT moved that the Education Committee be requested to consider whether the time had not come for erasing from the list of recognised preliminary examinations the examination for the second-class certificate of the College of Preceptors.

Mr. BRUDENELL CARTER seconded, and the proposal was adopted.

On the motion of Dr. BATTY TUKE, seconded by Dr. MACALISTER, the following report was also adopted:—

"The Education Committee reports to the Council that the Committee, having satisfied itself that the prescribed conditions have in each case been fulfilled, has resolved to insert in the list of recognised preliminary examinations held by Indian, Colonial, and Foreign Universities and Colleges the following—namely, University of Madras, First Examination in Arts; College of Physicians and Surgeons of New Brunswick, Matriculation Examination."

Professional Examinations.

Sir DYCE DUCKWORTH, on behalf of the Examination Committee, presented a report containing in a consolidated form the series of definitive recommendations suitable for transmission to the several licensing bodies throughout the Kingdom. He moved that the recommendations be approved and adopted.

Mr. BRYANT, who seconded the motion, said there was nothing new or fresh in the recommendations. All of them had been discussed over and over again.

At the instance of Dr. MACALISTER and Dr. GAIRDNER several verbal amendments were made, and Sir Dyce Duckworth's motion was then agree to.

An ex-President's Letter.

The PRESIDENT said he had received a short note from Sir Henry Acland, a former President of the Council, who had been present during part of the previous day's proceedings. In that Sir Henry Acland expressed what a great happiness it was to him to see the Council at work so wisely and so well and in such improved quarters. To him it was quite heart-lifting, and it made him thankful to and for the profession in many respects.

The Council greeted the reading of the letter with applause.

The Application of the Apothecaries' Hall of Ireland.

On the motion of Mr. WHEELHOUSE, seconded by Sir WM. TURNER, it was agreed: "That the President be requested to forward to the Lord President of the Privy Council a copy of the minutes of Wednesday, June 3rd, and Monday, June 8th, together with a letter to say that the General Medical Council had on these days, in accordance with a suggestion made by the Lords of the Privy Council, given their careful consideration to the application of the Apothecaries' Hall of Dublin for the appointment of examiners in medicine and surgery." It was further agreed that this resolution should be forwarded to the Lord-President and the licensing bodies interested.

Public Health.

Dr. THORNE THORNE, on behalf of the Public Health Committee, stated that owing to some deficiencies in the rules submitted to the Council last session the committee had by request considered the whole subject, and they had agreed upon the following as rules for diplomas in public health granted after January, 1897:—

"I. The Council, having regard to the terms of Section 18 of the Local Government Act (1888), and of Section 54 of the Local Government (Scotland) Act (1889), and observing that under those sections special privilege is to be accorded to the holders of the diplomas granted under Section 21 of the Medical Act (1886), and therein described as diplomas in Sanitary Science, Public Health, or State Medicine, thinks it essential to declare with regard to its own future action under Section 21 of the Medical Act (1886) that it will not consider diplomas to 'deserve recognition in the Medical Register' unless they have been granted under such conditions of education and examination as to ensure (in the judgment of the Council) the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health; and the Council, in forming its judgment on the conditions of education and examination, will expect the following rules to have been observed: 1. A period of not less than twelve months shall elapse between the attainment of a registrable qualification in medicine, surgery, and midwifery, and the admission of the candidate to any examination or any part thereof for a diploma in sanitary science, public health, or State Medicine. 2. Every candidate shall have produced evidence of having, after obtaining a registrable qualification, attended during six months practical instruction in a laboratory or laboratories, British or foreign, approved of by the body granting the diploma, in which chemistry, bacteriology, and the pathology of the diseases of animals transmissible to man are taught. 3. Every candidate shall have produced evidence that, during a period of six months after obtaining a registrable qualification, he has practically studied the duties of out-door sanitary work (*a*) in England and Wales either under the medical officer of health of a county or of a single sanitary district having at the date of the last census a population of not less than 50,000 or the medical officer of health of a combination of two or more sanitary districts having collectively at the date of the last census a population of not less than 35,000; or (*b*) in Scotland or Ireland under the medical officer of health of a county or of one or more sanitary districts having at the date of the last census a population of not less than 30,000; or (*c*) under a medical officer of health who is a teacher in the department of public health of a recognised medical school. The certificate of an assistant officer of health of a county or a large urban district may be accepted, provided the medical officer of health of the county or district consents to the assistant officer giving such instruction. Any candidate who shall produce evidence that he has himself held an appointment as medical officer of health under conditions not requiring the possession of a special sanitary diploma shall be exempt from this regulation. 4. Every candidate shall have produced evidence that he has attended the clinical practice of a hospital for infectious diseases recognised by one of the licensing bodies, provided that such a course of instruction may have been taken as part of the curriculum for his registrable qualification in medicine, surgery, and midwifery. 5. The examination shall have been conducted by examiners specially qualified; it shall have extended over not less than four days, one of which shall have been devoted to practical work in a laboratory, and one to practical examination in and reporting on subjects which fall within the special out-door duties of a medical officer of health. The rules as to study shall not apply to medical practitioners registered or entitled to be registered on or before Jan. 1st, 1890. II. The Council shall appoint an inspector or inspectors of examinations in public health with special instructions to report to the Council whether the examination of each body does or does not give evidence on the part of candidates passing such examination of a distinctively high proficiency, scientific and practical, in each and all of the branches of study which concern public health."

In presenting the report Dr. THORNE THORNE pointed out that it was requisite they should have a different regulation in regard to Scotland from that for England in connexion with the matter of population, and although Ireland had not as yet got a Local Government Act it had been deemed advisable to give Ireland the same position in regard to population. The provision (*c*) of Sub-section 3 was drawn to meet the case of officers who, though not in charge of districts with populations of 50,000, were teachers in recognised medical schools who had been most successful in their tuition. In regard to exemptions, it had been decided that all should go except the medical practitioner registered or entitled to be registered before January, 1890. He moved: "That the revised rules for diplomas in public health be approved and adopted and sent to the bodies granting the diplomas in question."

Mr. TEALE seconded, and the motion was carried unanimously.

Dr. THORNE THORNE next presented a report by the inspector, Dr. G. F. Duffey, appointed by the Council on the examination in preventive medicine for the diploma in public health of the University of Oxford. The report showed that the conclusion of the inspector was that both divisions of the examination "were satisfactory. They gave evidence that the candidates who obtained the diploma in public health of the University of Oxford possessed a distinctively high proficiency, scientific and practical, in all the branches of study that concern public health in which they were examined."

Dr. THORNE THORNE moved:—

"That copies of the first report of the Public Health Committee be forwarded to the proper authorities of the University of Oxford and that on this occasion no further action is required."

He explained that this was what had been done with the other bodies reported upon.

Dr. BRUCE seconded the motion, which also was unanimously adopted.

Midwifery Diplomas.

Mr. WHEELHOUSE submitted a report from the Midwifery Diplomas Committee with reference to allegations made in a memorial by Dr. Reid Rentoul in regard to the Rotunda Lying-in Hospital, Dublin, and the Coombe Lying-in Hospital, Dublin. The report stated:—

"On considering the allegations the committee finds that prior to

Digitized by Google

1860 only one qualification was required by the Local Government Board of Ireland for a Poor-law appointment; that at about that date an order was issued requiring candidates to produce evidence of competency in medicine, surgery, and midwifery; that up to that date the certificates complained of—the so-called 'diplomas'—were accepted as evidence of having 'studied midwifery,' and are still considered to be evidence of 'special education' in that subject, but are not, and never have been, regarded nor accepted as a 'licence to practise.' The Committee finds that in issuing these certificates the two institutions complained of have acted under Royal Charters, and, after carefully reading the Charters and the bye-laws of each of the hospitals, it reports to the Council the following facts: With respect to the Rotunda Hospital, in accordance with the powers granted by its Charter, which bears date Dec. 2nd, 1756, and was enlarged by Act of Parliament of 25th George III.: "The Master is authorised to receive such students—men or women—as intend to practise midwifery." And by by-law (No. 16) sanctioned by the Privy Council in accordance with the above-named Act of Parliament: "To issue a printed certificate, signed by the Master and one of the assistants to each pupil, male or female, who shall have served and attended a regular course in the said hospital, and that a certain seal shall be affixed thereto by the Registrar." The Committee further reports that the Latin certificate of the Rotunda Hospital has been in use for a period of more than a hundred years, and that it is granted as evidence of 'special education' only to registered medical students or qualified practitioners; and that an altogether different form thereto (see appendix) is issued to midwives and nurse-tenders. The Committee considers that both documents are in accordance with the powers granted by the Charter and confirmed by the Act of Parliament and are in no way a 'licence to practise' or intended as a colourable imitation of a registrable qualification. With regard to the Coombe Hospital, the Committee finds that the Master is authorised and directed by Royal Charter, dated Oct. 31st, 1867, 'to instruct students, male or female, in practical midwifery and the diseases peculiar to women and children, and to issue to such as pass a subsequent examination a certificate to that effect under his sign-manual. The Committee having carefully considered this Charter reports that, in its opinion, the certificate issued does not exceed the powers granted by the Charter; does not purport to be a 'licence to practise'; and that in its phraseology it is not a 'colourable imitation' of a 'registrable qualification.' As regards its appearance, the Committee notes that the form of the certificate of the Rotunda Hospital has existed unchanged for the long space of a hundred and forty years, and can hardly, therefore, be regarded as a 'colourable imitation' of any existing diploma, and that neither is the certificate of the Coombe Hospital. But the Committee is of opinion that, in consideration of the action taken by the General Medical Council in May, 1894, the time has come when both certificates should assume a more simple character, and recommends that the form, loyally adopted on a recent occasion by the Obstetrical Society of London, should also be accepted by the authorities of the Rotunda and the Coombe Hospitals; and, as the present masters at each of these hospitals have expressed in writing, in letters which have been laid before the Committee, their desire to conform to the wishes of the General Medical Council, it feels sure that on representation being made to them by the President of the Council to that effect, these bodies will, with equal loyalty, accede to his request; and that while continuing to issue their ancient certificate only to such persons as already possess a registrable diploma, or are registered, they should use the modified form for such as have no qualification.

In conclusion it was moved that the report be received and adopted, and that copies be forwarded to the masters of the two hospitals concerned.

Dr. ATTHILL in seconding the proposal took occasion to strongly protest against the charges which Dr. Rentoul had included in his memorial.

The motion was agreed to, and it was also agreed to forward a copy of the report to Dr. Rentoul.

Finance.

Mr. BRYANT presented the Finance Committee's report for the year 1895 which showed that the income of the General and Branch Councils amounted to £9097, and the expenditure to £9403, or an excess of expenditure over income of £306. He mentioned that there had been increase of expenditure for the Pharmacopœia, miscellaneous expenses, and fees, and an apparent increase in mortgage charges. There had been decreased expenditure in regard to law expenses, printing, inspection and visitation of examinations, &c. Altogether he thought the report was a fairly satisfactory one and he moved that it be adopted.

Sir DYCE DUCKWORTH seconded the motion.

Sir WILLIAM TURNER expressed the hope that in their next report the Committee would give particulars of the cost of the Council's new hall, especially seeing that the General Council was indebted to the English Branch Council to the extent of £20,000.

Mr. BRYANT having promised a detailed statement the report was adopted.

Students' Registration.

Sir DYCE DUCKWORTH presented the Students' Registration Committee's report on exceptional cases, which was adopted by the Council.

Voluntary Surrender of a Qualification.

Dr. ATTHILL explained this curious case to the meeting. The Royal College of Physicians of Ireland had the misfortune of having two members of the College settled in the same city, Exeter, and they did not agree. One of these gentlemen, Dr. R. L. Rutherford, wrote to the College asking whether its members were allowed to hold appointments as medical officers to Medical Aid Associations. He gave the name of a gentleman as acting for what Dr. Rutherford believed was a medical aid association. The reply was:—

"The College has expressed its strong disapproval of any of its licentiates holding the office of medical officer to a medical aid association, and that the same has been communicated to Dr. ——."

The letter to the gentleman in question was as follows:—

"The College have been informed that you are at present acting as medical officer of a medical aid association in Exeter. I am consequently to direct your attention to a resolution of the College adopted on Nov. 3rd, 1893, viz.: 'That the College of Physicians of Ireland desire to express their disapproval of their licentiates accepting office in medical aid associations as at present conducted in England, as the independence of the physician is destroyed by the system, and the services of the physician are used so as to produce a profit for lay persons.'"

To this the following reply was received:—

"I beg to state that you have been misinformed, for the association I am connected with is not an aid association, but one formed purely of friendly societies.

"As to sweating, there is no such thing in it, as my daily visiting has averaged for the last month about 28 (112 visits), and January is about the hardest month of the year.

"There are no profits made. The stipend is guaranteed, confinements extra, also certificates outside the societies."

There was simply, Dr. Atthill went on to say, a charge and repudiation, and therefore the College could do nothing. Dr. Rutherford therefore returned his diploma of Membership of the College dated 1882, and his Licentiate diploma of 1878, and requested that his name should be removed from the College list. The College had power to accept the resignation of any qualification, but owing to a by-law not having received Royal sanction, they could not yet act upon it. As to Dr. Rutherford's request to the General Medical Council for the removal from the Register of the qualification in question, he was in the hands of the Council itself.

After some conversation on the subject, the Council passed the following motion, proposed by Sir WALTER FOSTER and seconded by Dr. GLOVER—viz., "That the consideration of the correspondence sent to the Council by Dr. Rutherford be deferred until the Royal College of Physicians of Ireland has informed the Council of its further action in the matter." The programme of the day bore an intimation that Dr. Rutherford is also registered as M.D. Q. Univ. Irel., 1881, and Mast. Surg. R. Univ. Irel., 1882.

Duties of the Penal Committee.

On the motion of Dr. LEECH, seconded by Dr. BRUCE, the Council agreed to request the Education Committee to revise the standing orders so as to include a sub-section defining the duties of the Committee for penal cases in connexion with all such cases referred to the Committee.

The Case of Mr. Joseph Stromier.

Mr. BRYANT presented a report by the Dental Education and Examination Committee with reference to a communication from the British Dental Association on the case of Mr. Joseph Stromier of Glasgow. The Committee said that they had considered the communication of the Association with the explanation offered by the Faculty of Physicians and Surgeons of Glasgow, and they reported that they did not find that there had been any irregularity in the action of the Faculty with respect to the candidate named, seeing that he was only admitted to examination for the L.D.S. on submitting evidence acceptable to that Faculty that he had duly attended the courses prescribed for the examination.

The Case of Mr. James Findlay.

The Council passed a resolution authorising the restoration to the Medical Register of the name and qualification of Mr. James Findlay, at present residing at Penpont, Dumfriesshire.

The Council then re-elected the Executive Council and re-arranged the other Committees, and adjourned till November.

HOME FOR THE DYING.—A concert was given at Stafford House on Tuesday afternoon in aid of the Free Home for the Dying at Clapham. A large audience was present, and a well-arranged programme was gone through under the management of Mr. William Nicholl.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Copenhagen:* Dr. Knud Faber has been appointed to the Professorship of Clinical Medicine in succession to Dr. With, resigned.—*Leyden:* Dr. J. Veit of Berlin has been appointed Professor of Midwifery and Gynæcology.—*New York (Post-graduate School):* Dr. Eugène Fuller has been appointed Professor of Genito-urinary Surgery and Dr. J. M. Woodbury Professor of Orthopædic Surgery.—*Vienna:* Dr. C. Büdinger has been recognised as *privat-docent* in Surgery.

THE tourist steamer, *Midnight Sun*, sailed from the Tyne on Saturday evening with 200 passengers for the Norwegian Fjords. This is probably the largest number of tourists that any steamer has ever taken at the opening of the Norwegian tourist season.

FATAL ACCIDENT TO DR. EVANS OF SHAFTESBURY, DORSETSHIRE.—A shocking carriage accident occurred on June 5th, resulting in the death of Mr. Charles Silvester Evans, M.A., M.B. Cantab. The horse he was driving bolted and dashed into a shop window, and Dr. Evans sustained fatal injuries. Dr. Evans was educated at St. Thomas's Hospital and Cambridge, graduating with the M.A. and M.B. B.C. in 1887, having taken the qualifications of M.R.C.S. Eng. and L.S.A. in 1886. He was medical officer for the Fontmell District of the Shaftesbury Union and to the Cottage Hospital and the police, and had formerly held the appointments of house physician, assistant house physician, and assistant house surgeon at St. Thomas's Hospital.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—Mr. Edward T. Carlyon, M.B. Durh., L.R.C.P. Lond., recently of Yarmouth, has been presented by the inhabitants, since his departure from that town, with a testimonial, which comprised a beautifully illuminated address, signed by 350 subscribers, and a purse of sovereigns.—Dr. John Watson of Newbury has been the recipient from the members of the Newbury ambulance classes of a silver-topped inkstand, suitably inscribed, in appreciation of his services as their lecturer on First Aid.—On leaving the Hospital for Sick Children, Great Ormond-street, after three years' tenure of office as medical superintendent, Mr. T. H. Kellock, F.R.C.S. Eng., &c., was presented by the matron and members of the nursing staff with two cases containing sets of tracheotomy and intubation instruments. He was also the recipient of a handsome marble clock presented by past and present residents and registrars.

MR. KENDAL FRANKS, F.R.C.S. IREL.—It having come to the knowledge of the Council of the Royal College of Surgeons in Ireland that, owing to Mrs. Franks' ill health, it is the intention of Mr. Kendal Franks, Vice-President of the College, to leave Dublin in August to settle in South Africa, they felt that his professional friends would wish to avail themselves of an opportunity of showing their respect and esteem for him prior to his departure. With this object the Council resolved itself into a committee to organise a farewell banquet to be held in the College, and elected the President, with Mr. R. L. Swan, Mr. Austin Meldon (hon. treasurer), and Mr. F. T. Heuston (hon. secretary) as a sub-committee to arrange details. The banquet is to be held on Thursday, June 25th. Members of the profession wishing to join should send their names to Mr. G. F. Blake, Registrar, Royal College of Surgeons, Dublin, before Monday, June 15th, as it is intended to engross the names of those joining on an address to be presented at the banquet.

THE DIFFUSION OF SMALL-POX.—There was no death registered from small-pox last week in any of the thirty-three great towns of the Registrar-General, but Gloucester finds place in the weekly return as having had 11 deaths registered, all of persons belonging to the city. As regards London, last Saturday saw only 21 patients suffering from small-pox still under treatment on board the hospital ships in Long Reach. There has been but little manifestation of the disease around the metropolis, and last month there were but half a dozen cases in West Ham. At Gloucester the week ended with Thursday of last week witnessed some rise in the number of notified cases of small-pox, the total reaching 56 fresh cases, as compared with 42 in the preceding week. However, 44 discharges took place, as against 12 admissions to hospital, but there were 3 deaths in hospital and 6 in the invaded households. The Education Department have been in correspondence with the Gloucester School Board on the subject of the exclusion of children not successfully vaccinated, as well as of children whose parents refuse information on the matter. The central education authority have assented to such procedure. The Gloucester School Board are about to petition the London authority to grant them special treatment in the way of grant now that, the schools being re-opened, the scholars are attending in such small numbers. The school board have our sympathy in their endeavours to curtail the epidemic, and we trust that the central authority will see their way clear to some exceptional treatment of the Gloucester board, so that no loss may be experienced in regard of the annual grant by reason of smallness of attendance at the present time. It appears that among the 2000 members of the Order of Foresters at Gloucester there has been expended for funerals of small-pox patients the sum of £120 and a like amount for sick pay. Some statistics of the hydropathic treatment committee at Gloucester show that of 177 patients treated by a Mr. Pickering on this method, 18 have died, or 10 per cent., and that the majority of those "cured" have been "cured" within a week. The point that arises in our mind is whether any "cure" of a small-pox patient effected within a week may not by its very speed be the means of further spread from the individual treated if he mix with his fellows immediately afterwards. We all know the danger arising from the intercommunication of sick and healthy in the case of mild attacks of small-pox, where the patients feel little or no inconvenience from the malady, and thus do not refrain from following their usual avocations. A second case of small-pox has occurred at Worcester in the person of the wife of the first patient who fell ill the day following his arrival from Hamburg. Both patients are in hospital. In view of small-pox of recent occurrence at the Mumbles, the Oystermouth district council have instructed their medical officer of health to proceed to offer special facilities for vaccination, and propose, if the Gower guardians offer any objection, to pay the costs themselves. Small-pox has broken out in two houses at Garston, near Liverpool, five cases having been recorded and removed to hospital. The houses, situated near the docks, have been thoroughly disinfected and placed under quarantine. A further death from small-pox took place in the Heywood Hospital on the last day of May, and two patients have been removed to hospital at Royton. In both places the guardians refuse to enforce the Vaccination Acts.

IMPROVEMENTS IN LIGHTING.—The question of lighting both in our streets and for ordinary domestic purposes is one of such importance from the hygienic point of view that the formation of an influential body to develop and "engineer" any new system which gives promise of advance should be welcomed. Such would appear to be the aim of the Lighting Corporation, Limited, the installation of which was signalised by a banquet given on the 2nd inst. We understand that this corporation has been formed with the view of acquiring any system of lighting which gives evidence of improvement upon existing systems in regard to lighting efficiency, economy, and its hygienic aspect. At present, however, their operations are confined to the development and improvement of the well-known Wenham regenerative burner. The principle of this burner consists in heating the gas before it is burnt, so that the gas is made more luminous by the so-called regenerative process. However that may be, the burner is so constructed as to effect a powerful ventilating action upon the air of the room, while at the same time the products of combustion are carried away. Experimental evidence of this ventilating action was shown on the occasion of the banquet referred to, when the underground room in which the banquet was held was illuminated by means of Wenham burners. In spite of the oppressive heat of the weather at the time the room was comparatively fresh and cool, and when smoking was commenced by some 200 persons present the air remained practically unclouded. Moreover, the products of combustion being carried away very little heating effect upon the air of the room takes place, while the deteriorating effects of the products of the combustion of coal gas are entirely avoided. The light serves well for street-lighting purposes since its strong sunlight colour is highly penetrative. In this way the Wenham burner plays an important part as a lighting appliance possessing hygienic advantages. The Lighting Corporation have established offices at 4, Bloomsbury-street, W.C., where an excellent installation of the Wenham system may be viewed.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Midwives Registration Bill.

THIS Bill has not been withdrawn as seems to be supposed in some quarters. It still appears among the orders of the House of Commons, although, having regard to the period of the session and the pressure of Government business, there is practically no chance of its being discussed.

The Clothing of the Metropolitan Police.

In the course of the debates in Committee of Supply last week the old question was raised of providing lighter clothing for the Metropolitan Police to wear in very hot weather and the same official answer was given—namely, that the authorities, with every desire to contribute to the health and comfort of the force, have given the matter their attention and see no sufficient reason for altering the present arrangements.

HOUSE OF COMMONS.

THURSDAY, JUNE 4TH.

New Commission on Tuberculosis.

Mr. Chaplin, in answer to Dr. Farquharson, said that the proposed terms of reference to this Commission were to inquire and report as to what administrative procedures are available and would be desirable for controlling the danger to man through the use as food of the meat and milk (with its products) of tuberculous animals, and what are the considerations which should govern the action of the responsible authorities in condemning and not condemning, for the purposes of food supplies, animal carcasses or meat exhibiting any stage or stages of tuberculosis. He was not in a position at present to announce to the House the names of the members of the Commission.

Calf Lymph.

Sir William Priestley asked the President of the Local Government Board whether, in view of the increasing demand for vaccination with calf lymph, he would consider the expediency of at once taking such steps as might be necessary to facilitate the performance by public vaccinators of calf to arm vaccination, with the double object of meeting the objections of an increasing number of parents to the use of humanised lymph, and the protection of infants from the danger of attack and death by small-pox.—Mr. Chaplin replied that he was fully aware of the importance which was attached to the performance of vaccination direct from calf to arm when calf lymph was used. But his hon. friend must be aware that a system of calf to arm vaccination if practised generally would involve an entirely new organisation at a very large expenditure of public money; and since the desirability of introducing changes "for the purpose of removing objections to vaccination or making it more effective" was included in the reference to the Royal Commission on Vaccination, who were now engaged in compiling their report, he doubted the expediency of his making any proposal as to the alterations in the law and its administration which would be involved before he had had the advantage of considering their report.—Mr. Gibson Bowles asked the right hon. gentleman whether he could tell the House when they would have the report of the Commission.—Mr. Chaplin: No, sir, I wish I could.

FRIDAY, JUNE 5TH.

River Pollution.

Mr. Cohen, on behalf of Mr. Herbert Robertson, asked the President of the Local Government Board whether he was aware that the waters of the river Lea were polluted by the introduction of insufficiently disinfected sewage matter from the districts of Tottenham, Walthamstow, and Leyton, greatly to the detriment of the health of the inhabitants of South Hackney and other districts; and whether he could take any, and what, steps to prevent this infringement of the Rivers Pollution Acts.—Mr. Chaplin replied: As regards the pollution of the waters of the river Lea, I have been in communication with the district councils of the three districts referred to in the question. In the case of Tottenham, I am informed that the whole of the sewage of the district is pumped direct from the outfall works into the sewers of the London County Council. I do not find that the Local Government Board, during the last two years, have received any complaint in this matter as regards the Leyton district. With respect to Walthamstow, proceedings were instituted by the Leyton District Council for the purpose of obtaining an injunction to prohibit the pollution of the river by sewage from that district. An injunction was granted and the district council have submitted proposals for additional works with a view to preventing a continuance of the pollution. The Local Government Board have no authority to institute proceedings under the Rivers Pollution Acts; proceedings under those Acts may be instituted by the county council or the council of any district affected by the pollution. Moreover, any powers which the Lea Conservancy Board have as regards the pollution of the river have been reserved to them by the Rivers Pollution Prevention Act of 1876.—Mr. Bartley asked the President of the Local Government Board whether his attention had been called to the filthy condition of the river Brent after it received the sewage water from the sewage farm at Ealing, Middlesex; whether he was aware that this stream runs close to the large district schools with some thousand children and through the densely populated district of Brentford; and, whether he would cause a local inquiry to be made with a view of putting a stop to the serious danger to the health of the neighbourhood from this polluted stream.—Mr. Chaplin said in reply: The attention of the Local Government Board was directed last year to the condition of this river, and the Board, after obtaining a report from one of their inspectors on the subject, communicated with the Thames Conservancy Board and the County Council urging that action should be taken with the view of preventing the continuance of pollution of the river. In consequence of the reference in the question of the Ealing district, I have made inquiry of the council of that district, and am informed that there is no source of pollution within their district, and that, with the view of preventing pollution of the river by others, they have determined to take steps to obtain an injunction. With respect to the Willesde District Council, the effluent from whose works was regarded by th Thames Conservancy as unsatisfactory, the Local Government Boa have now before them an application from the council for sanction to loan for the improvement of their works of sewerage and sewage di posal. Powers of instituting proceedings for preventing pollution a vested in the Thames Conservancy and the County Council, and I wi again communicate with these authorities.

MONDAY, JUNE 8TH.

The Vaccination Question.

In reply to a question by Colonel Russell as to when the report of th Royal Commission on Vaccination might be expected, Mr. Chapl said that the reply which he had received to his inquiries on th subject was that it was impossible to say beforehand how much tim would be occupied by the discussion of a report and the modificatio consequent on such discussion. The Commission were approaching th completion of their labours and there would be no unnecessary delay.- Mr. Seton-Karr asked the right hon. gentleman whether he was awa that the Lynn guardians, by a vote of 15 to 5, had recently rejected resolution to enforce the compulsory clauses of the Vaccination Act whether it was a fact that there were 605 births in Lynn last year as only eleven vaccinations; and, whether, under these circumstance and in view of the recent prevalence of small-pox at Gloucester, th Government proposed to take any steps to secure the proper an general enforcement of the Vaccination Acts.—Mr. Chaplin replied: understand that the facts with regard to the resolution passed by th guardians of the King's Lynn Union and the number of vaccination are as stated in the question. I have addressed a communication t the guardians pointing out that by their acceptance of the office o guardians they have undertaken to discharge the duties which devolv on them, including those with regard to vaccination, and impressing o them that by failing to enforce the provisions of the Vaccination Ac they are incurring a very grave responsibility. They have at the sam time been reminded of the experience of Gloucester, where nearly 19 cases of small-pox have recently occurred as evidence of the serio consequences which may at any time befall a community in whic vaccination has been persistently neglected. I hope that on furth consideration the guardians will not fail to take the action which i necessary for the enforcement of vaccination in their union.

TUESDAY, JUNE, 9TH.

Army Medical Department.

In reply to Dr. Tanner Mr. Brodrick, Under Secretary of State fo War, said there was no intention to lower the standard of examinatio for admission to the medical staff. The only change made was tha more marks would be allocated to the practical subjects of medicin and surgery, with the view of obtaining the best practical medical me In February, 1895, there were seventeen candidates for twelve vacancie in August following twenty-three candidates for thirteen vacancie and in February last eighteen candidates for seventeen vacancies. A he stated recently the decrease in candidates was engaging Lor Lansdowne's serious attention.

Workhouse Administration in Ireland.

Mr. Gerald Balfour announced, in reply to a question, that the Bil with regard to workhouse administration in Ireland was nearly ready but in the condition of public business he was afraid that unless he wa allowed to introduce it after twelve o'clock it could not be introduce this session.

WEDNESDAY, JUNE 10TH.

Experiments on Living Animals.

On the motion of Mr. Jesse Collings, Under-Secretary of State fo Home Affairs, a return was ordered showing the number of experiment performed on living animals during 1895 under licence of the Hom Office, distinguishing painless from painful experiments.

SEAMAN'S HOSPITAL SOCIETY (*Dreadnought*).—House Surgeon for Branch Hospital, Royal Victoria and Albert Docks, E. Salary £75 per annum, with board and residence.—Applications to the Secretary, Greenwich, S.E.
STOCKPORT INFIRMARY.—Assistant House and Visiting Surgeon. Salary £70 a year, with board, washing, and residence.
WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, PARALYSIS, AND EPILEPSY, 73, Welbeck-street, London.—Physician.
WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—Resident Medical Assistant for six months. Board, lodging, and washing provided.

Births, Marriages, and Deaths.

BIRTHS.

ANDREWES.—On June 7th, at 35, Welbeck-street, W., the wife of F. W. Andrewes, M.D., of a son.
BURTON-FANNING.—On June 6th, at Norwich, the wife of F. W. Burton-Fanning, M.B. Camb., M.R.C.P. Lond., M.R.C.S., of a son.
COLLIER.—On June 4th, at Clarence Villa, Hartfield-road, Wimbledon, the wife of S. Ruddell Collier, M.D., of a daughter.
EHRHARDT.—On June 4th, at Portland House, Bridge-road, W. Battersea, the wife of J. M. Ehrhardt, L.R.C.P.I., of a daughter.
GRIFFITHS.—On June 5th, at 63, Trumpington-street, Cambridge, the wife of Joseph Griffiths, M.D., F.R.C.S., of a son.
HOWARD.—On May 30th, at Queen Ann-street, W., the wife of R. J. E. Howard, M.D., F.R.C.S. Eng., of a son.
KERR.—On May 27th, at Keelby, Brocklesby, Lincs., the wife of D. Oliver Kerr, M.B., C.M., D.P.H., of a daughter.

MARRIAGES.

ARCHER—WYNTER-BLYTH.—On June 4th, at St. Paul's Church, Avenue-road, N.W., Lewis Stafford Archer, M.R.C.S., Eng., L.R.C.P. Lond., of Upper Avenue-road, N.W., and Hillfield-road, West Hampstead, to Julia, elder daughter of A. Wynter-Blyth, M.R.C.S., Medical Officer of Health for Marylebone, and Barrister-at-law, of Norfolk-road, N.W.
CREASY—NEALE.—On June 6th, at Christ Church, Ealing, Lawrence Eliot Creasy, M.R.C.S., L.R.C.P., of Windsor-road, Ealing, to Maud Ann, eldest daughter of Frederick Neale, of Woodville, Ealing.
CREE—SMITH.—On June 3rd, at the Church of St. Philip and St. James, Cheltenham, Surgeon-Captain Gerald Cree, Army Medical Staff, son of E. H. Cree, M.D., Deputy Inspector-General, R.N. (retired), to Isabella Sophie Alice, only daughter of Philip Broke Smith, M.D., Surgeon-Major-General, late A.M.S.
COLLIER—BOWATER.—On June 6th, at St. John's Church, Lewisham, Kent, Henry William Collier, M.B., B.S. Lond., of Adderbury, Oxon, only son of Henry Collier, of Forest-hill, to Gyneth, daughter of Francis Bowater, of Apna Ghur, St. John's.
LEAF—GRIERSON.—On June 6th, at St. Barnabas Church, Addison-road, by the Rev. William Leaf, M.A., Curate of Holy Trinity, Southwark, assisted by the Rev. G. R. Thornton, Vicar of the Parish, Cecil Huntington Leaf, M.A., M.B., F.R.C.S., to Fanny, daughter of the late James Grierson, of 4, Holland Villas-road, Kensington.
STEVENS—FRANKLIN.—On June 1st., at St. Anthony of Padua, Lordship-lane, by Very Rev. Provincial of Discalced Carmelites, Francis Joseph Stevens, B.A., M.R.C.S., Medical Officer of Health of Camberwell, youngest son of Thos. Stevens, Barrister-at-Law, to Annie Evelina Whidborn, (Faggie), only daughter of the late Dr. Henry Franklin of Clerkenwell and Islington.
THOMPSON—COTTON.—On June 9th, at St. John's, Hampstead, Charles Sinclair Thompson, M.B., of Bideford, to Florence, eldest daughter of the late Francis J. Cotton, of The Knoll, West Hampstead.
WITHERS—SUMMERS.—On June 9th, at St. Peter's, Ashton-under-Lyne, Percy Withers, M.B., of Ashford, Hale, Cheshire, to Mary Woolley, youngest daughter of the late John Summers, of Sunnyside, Ashton-under-Lyne.

DEATHS.

COCKELL.—On June 3rd, at Widecombe-crescent, Bath, Philip Wyatt Cockell, Brigade-Surgeon-Lieutenant-Colonel, Bombay Medical Staff Corps, retired, aged 64.
EVANS.—On June 5th, at Shaftesbury, Charles Silvester Evans, M.A., M.B., B.C. Cantab., M.R.C.S., in his 36th year.
GRIFFITH.—On May 27th, at Huntworth, Bedford, David Charles Ballinger Griffith, M.R.C.P. Edin., eldest son of the Rev. T. C. Griffith, of Norman Hill, Gloucestershire, aged 50.
HUDSON.—On April 28th, 1896, at George, Cape Colony, F. J. Hudson, M.B. Aberd., District Surgeon, George, aged 34.
HUNTER.—On June 7th, at The Poplars, Pontypridd, after a few days' illness from pneumonia, Thomas Canning, Physician and Surgeon, son of Dr. Hunter, J.P., aged 28.
JOHNSON.—On June 3rd, at Savile-row, Sir George Johnson, M.D., F.R.S., Physician Extraordinary to H.M. the Queen, in his 78th year.
LANGSHAW.—On June 5th, at Elmside, Lancaster, James Pearson Langshaw, F.R.C.S., aged 82.
MORRIS.—On June 3rd, at The Grove, Camberwell, Isaac Morris, M.D., of Wallands-crescent, Lewes, aged 56 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

FRIDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.) Gt. Northern Central (2.30 P.M.).

SATURDAY (20th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (17th).—ROYAL METEOROLOGICAL SOCIETY (22, Gt. George-st., Westminster).—7.30 P.M. Papers:—Mr. H. Harries: Arctic Hail and Thunderstorms.—Mr. J. E. Cullum: Climatology of Valencia Island, co. Kerry.—Dr. H. E. Leigh Canney: The Winter Climate of Egypt, based on results from Self-recording Instruments, 1893-6 (this paper will probably also be read).

ROYAL MICROSCOPICAL SOCIETY (20, Hanover-sq., W.).—8 P.M. Meeting.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (Limmer's Hotel, Conduit-street, W.).—8.30 P.M. Dr. C. T. Williams: Seabathing and the Open-air Treatment of Disease. Followed by a Conversazione.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (15th).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Mr. G. C. Wilkin: Syphilis of the Pharynx and Larynx.

WEDNESDAY (17th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Dr. Beevor: Peripheral Neuritis.

HOSPITAL FOR CONSUMPTION, &c. (Brompton).—4 P.M. Dr. S. Martin: The Early Diagnosis of Pulmonary Tuberculosis.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Payne: Eruptions produced by Drugs.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Keetley: Surgical Cases.

THURSDAY (18th).—LONDON POST-GRADUATE COURSE.—Brit. Inst. of Preventive Medicine, Gt. Russell-st., W.C., 3.30 P.M., Dr. Allan Macfadyen and Mr. A. G. Foulerton: Detection of Pathogentic Micro-organisms in Urine.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Dr. R. Harrison: Clinical Lecture.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-st., W.C.).—4 P.M. Lecture by Dr. Barlow.

VICTORIA HOSPITAL FOR CHILDREN (Tite-street, S.W.).—4 P.M. Dr. W. Carr: Pneumonias in Children and their Sequels.

FRIDAY (19th).—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Erysipelas and Suppuration.

ROYAL INSTITUTION.—9 P.M. Mr. T. C. Martin (New York): The Utilisation of Niagara (with Illustrations).

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

A POINT OF CONDUCT.

To the Editors of THE LANCET.

SIRS,—Will you kindly give your opinion on the following point of medical etiquette? A. and B. are general practitioners in the same town. B. sees a patient in consultation with A. After a little time A. is told by the family that they do not wish him to attend them any longer and intend to place themselves in B.'s hands. B. expresses great regret to A., but takes the patient on the ground that if he did not someone else would. Was B.'s conduct right?—I am, Sirs, yours faithfully,

June 2nd, 1896. X. Y. Z.

*** It is to be regretted that B. considered it his duty to attend the case in the place of A., who introduced him to the house; but in the absence of further information B. must be credited with perceiving circumstances which compelled him to act in this manner. It is always a pity when the particular situation arises that has been laid before us, and the mischief recoils on the heads of the public, who may thereby lose the security that lies in consultation. A medical man cannot be expected to disinterestedly call in a brother practitioner if he feels that the course may lead to his being at once supplanted. But it must not be forgotten that every patient has a right to employ any medical man he chooses.—ED. L.

PIG *v.* OX BILE TABLOIDS IN JAUNDICE.

MESSRS. BURROUGHS, WELLCOME, AND CO. write us that, acting on Dr. George Harley's suggestion in THE LANCET of May 30th that the bile of the omnivorous pig is more likely to contain "exactly the ingredients necessary to supply the place of those that are absent from the digestive canal in cases of jaundice" than that of the herbivorous ox, they have prepared tabloids of compressed pig-bile, each tabloid containing four grains. Messrs. Burroughs, Wellcome and Co. have certainly lost no time in affording the profession an opportunity of practically testing Dr. Harley's suggestions.

THE ADMINISTRATION OF GUAIACOL.

To the Editors of THE LANCET.

SIRS,—Permit me to ask the favour, in your correspondence pages, of me of your contributors or readers detailing the methods of administering guaiacol or guaiacol carbonate, by vapour and by external application, to the skin of the thigh. I am, Sirs, yours faithfully,

June 10th, 1896. SURGEON.

AB UNO DISCE OMNES?

he *Pall Mall Gazette* of May 28th is responsible for the following paragraph under the heading "Silk and Stuff":—

> "A case which ought to become a leading one on the fallibility of doctors in distinguishing between a drunken and epileptic fit was heard at the Lambeth Police-court on Tuesday. A highly respectable young woman from Brentford was charged with being drunk and lying insensible in a tram-car. The medical gentleman called in by the police 'formed the opinion that she was suffering from the effects of drink.' Yet it turned out that she was well known to be subject to epilepsy, was a total abstainer, and had never tasted a drop of alcohol in her life. Moreover, the conductor had not noticed any trace of insobriety in her demeanour on entering the car, and it is to be presumed that drink is not to be obtained there during the transit. Thus the doctor was hopelessly wrong. The moral seems to be that while a doctor should be called in to every such 'charge' without exception, his uncorroborated testimony should never be sufficient."

The *Pall Mall Gazette's* logic is surely somewhat amiss. Because a certain "medical gentleman" formed an erroneous opinion that a respectable woman was suffering from the effects of drink, therefore the moral remains that no medical man's uncorroborated testimony should ever be sufficient,—to us this seems to be a flagrant example of an argument from the particular to the universal. It has ere now arrived to most papers, morning and evening alike, to disseminate inaccurate intelligence. Should the public on that account invariably decline to believe in any utterances whatsoever of the journal once caught tripping? We venture to think that the two propositions are parallel.

WANTED, AN EXACT DIAGNOSIS.

To the Editors of THE LANCET.

SIRS,—I was called in on Sunday morning to visit Mrs. ——, nd found her to be suffering from a very acute diarrhœa and ollapsed; the temperature was 95° F. and the pulse 50. I at once rdered stimulating and other appropriate treatment, but despite all fforts she died on Sunday evening about 6.30 P.M., conscious to the st. This patient had been ill from the Thursday night. I could trace o irritant poison or any unwholesome food, and turned my attention o the milk and water supplies. The former I found good; the latter on xamination I found contained a large quantity of animal matter, itrites, and nitrates, the sources of the spring receiving all the rainage from the adjoining cemetery not more than 100 yards away nd the percolation from a huge heap of manure and stable refuse. A eek later I was called in to see Mr. ——, sen., the father-in-law of the eceased woman, and found him suffering from the same complaint (he ll ill about four days after the death of his daughter-in-law); a day fter his daughter and son were also taken with the same complaint. hey, too, all showed signs of collapse, and notwithstanding my tmost endeavours he passed away after a week's illness, the other wo patients recovering. An examination of the water showed marked ollution. The strange part I now relate. A Mrs. ——, who acted as urse and whom I warned against drinking the water, and who denied aving touched a single drop of food (fluid or solid) in that house, also ell ill with the same complaint, and after a more or less protracted onvalescence made a fair recovery. The brother of the patients and all heir relatives suffered from this choleraic diarrhœa, and I could ccount for the diarrhœa by nothing except the water after the closest nd most minute investigation. Yet it appears that it must have been ontagious, since all the relatives who came to the house or who ttended the first patient's funeral were in turn attacked, and even he families who did not come, as being too young, of those who ttended the funeral suffered more or less acutely. Microscopical xamination of the stools revealed nothing except what I took to be the acillus coli communis. The first death was certified as acute intestinal atarrh and the second as choleraic diarrhœa, but some light on these ases would be of great benefit to me.

I am, Sirs, yours truly,

Ilminster, June 1st, 1896. CHARLES A. FRANCOIS.

Ethics has not made his questions very clear. Are we to understand that the person represented as a tout is a medical man or only the agent of a medical man? There can be no doubt that the conduct described is unprofessional, but the local medical society could hardly take notice of it unless the examples were several and well authenticated.

Warwick.—We regret that we cannot advise medical treatment or recommend individual practitioners, but the family medical man will be able to say whether the process of electrolysis would be of use and to make arrangements for a trial thereof. Skin-grafting has also proved successful.

"THE TREATMENT OF PLEURITIC EFFUSION."

To the Editors of THE LANCET.

SIRS,—In answer to the letter on the above subject by "Ubique" in THE LANCET of May 30th I should suggest the following line of treatment:—First of all re-aspirate and then inject into the pleural cavity from 15 to 30 minims of a solution of corrosive sublimate of the strength of 1 grain to the ounce of distilled water = $\frac{1}{437}$ to $\frac{1}{875}$ gr. hydrargyri bichloridum. Then close the wound with a collodion pad, and finally apply a piece of lint sprinkled with linimentum belladonnæ and then bandage. This treatment is on the lines of the article "Curative Treatment of Vaginal Hydrocele by Corrosive Sublimate" written by my father, Dr. James Miller, in THE LANCET, 1886, who would, I have no doubt, forward a copy of the article to "Ubique" upon his applying to him for same.

I am, Sirs, yours faithfully,

J. T. ROGER MILLER, L.R.C.P. & S.I., &c.,

Malton, June 1st, 1896. Hon. Surgeon to Malton Public Dispensary.

ARMY MEDICAL SERVICE.

A COMBATANT officer writes to us advocating the introduction of a short-service system into the army medical service. He suggests that appointments should be for six years, say, or for some definite period, with a bonus instead of pension at the end of it, and that the Government should have the option of selecting such medical officers as had shown ability and military aptitude, and were willing to remain, as were required to fill the more permanent and administrative ranks of the medical staff, placing the latter upon exactly the same footing as to rank and position as the officers of the Royal Engineers. He points out that in this way the State and the medical profession would equally get what they want and a large medical reserve would be formed. But neither our correspondent nor the advocates of such an organisation seem to be aware of the fact that an essentially similar measure was put forward and adopted many years ago, and had to be abandoned for the simple reason that it proved a failure.

IODISM.

To the Editors of THE LANCET.

SIRS,—In the issue of THE LANCET of May 30th Dr. S. West mentioned one or two apparently doubtful preventives of iodism during the administration of iodide of potassium. Some years ago I had a patient suffering from acute pain in the head, obviously rheumatic in character, for whom I prescribed the iodide. So serious, however, were the effects of the drug that he absolutely refused to continue it after the first few days. The pain speedily subsided, but recurred some months afterwards, and so severely that he only found relief from repeated hypodermic injections of morphia. As, however, the morphia was simply allaying the pain without in the least affecting its cause I with much persuasion induced him to resume the iodide. To my surprise I found that he could take it then with perfect impunity. Afterwards I got into the habit of prescribing it with small doses of morphia and was rarely if ever troubled with iodism. But it is not always desirable to administer morphia, and lately, where that drug has been contra-indicated, I have used atropia sulphate instead with very gratifying results. I am, Sirs, yours truly,

Gourock, June 2nd, 1896. A. VEITCH.

IMPROVED ADHESIVE PASTE.

WE have received from the Morgan's Hungarian Paste Co., 153, Colegrave-road, Stratford, E., a specimen of their commodity, which is said to possess certain advantages over others in use. Foremost among these are evidently its good white colour, its uniformity of composition, and its keeping properties, while it is powerfully adhesive. It contains an agreeable and effective preservative. Its basis is starch, as shown by the iodine test.

Anxious should consult her medical attendant.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Eastern Morning News, Bradford Observer, Manchester Courier, Philadelphia Inquirer, Times of India, Cape Times, Pioneer Mail, Brisbane Courier, Glasgow Herald, Sussex Daily News, Newcastle Journal, South Wales Daily News, Liverpool Daily Post, Chatham News, Western Mail, Midland Free Press, Leicester Post, Northern Echo, Birmingham Post, Worcester Herald, Southampton Times, Yorkshire Post, Rochester Journal, Rangoon Times, Manchester Evening Mail, Bristol Mercury, Scotsman, Builder, Liverpool Courier, Worcestershire Chronicle, Leeds Mercury, Horncastle News, Cheshire City News, Donegal Independent, Hemel Hempstead Gazette, Hertfordshire Mercury, West Middlesex Standard, Weekly Free Press and Aberdeen Herald, Public Health, Reading Mercury, Gazette and News (Blackpool), Local Government Chronicle, City Press, Guy's Hospital Gazette, Macclesfield Courier, Surrey Advertiser, Gloucestershire Chronicle, Local Government Journal, Mining Journal, Kent Messenger, Record, Financial News, Bradford Evening Telegraph, Darwen News, Barnsby Chronicle, South Eastern Gazette, Shanghai Mercury, Melbourne Argus, Lyttelton Times (Christchurch, N.Z.), Middlesex and Surrey Express, &c., &c.*

The Croonian Lectures:

A CONTRIBUTION TO THE STUDY OF THE BLOOD AND THE CIRCULATION.

Delivered before the Royal College of Physicians of London,

BY GEORGE OLIVER, M.D., F.R.C.P. LOND.

LECTURE III.[1]

Delivered on June 9th.

THE BLOOD.

MR. PRESIDENT AND GENTLEMEN,—In this and the following lecture I propose to submit the results of some observations made with the view of inquiring into the physiology of the red blood corpuscle.

Notwithstanding recent advances in our knowledge of the chemical, histological, physiological, and pathological aspects of the blood there still remains much to be learnt in regard to the definite influence of the leading physiological conditions and processes upon the life history of the red corpuscle. There are certain views entertained as to its birthplace and as to how it terminates its little cycle of life, and we know well enough the all-important rôle it plays in the organism which it serves; but our present knowledge of the physiology of the corpuscle fails to furnish definite answers to such questions respecting it as the following. What is the influence of the different physiological conditions that obtain from hour to hour, and indeed from day to day and from week to week, on the relationship which subsists between the corpuscle and the plasma on the one hand and the hæmoglobin on the other? What are the ordinary limits of the variations thus induced in health and, furthermore, in disease? Does such a physiological process as that of digestion, which has a far-reaching influence throughout the organism, affect the red corpuscle either in regard to its development and growth or to its dissolution, or in regard to its relations to the plasma and to the hæmoglobin? In other words, what is the physiological history of the corpuscle from the inception of food to the absorption of the products of digestion? What is the influence of water? Is the red disc in its twofold relations to the plasma and to the hæmoglobin affected by rest and exercise? Under what physiological conditions does the hæmoglobin value of the corpuscle rise and fall? The solution of such questions as these is highly desirable from a purely physiological standpoint, and it is, moreover, an absolutely necessary preliminary to any satisfactory clinical hæmometric observation.[2] The present inquiry was undertaken in the hope that it might elicit some facts which may form a contribution, meagre though it be, towards this end. It was, however, soon apparent at the very outset of it that though it was comparatively limited in scope it was, nevertheless, one that would claim the labour of some years before it yielded a full answer; therefore, the few results which have been gleaned during the past twelve months can only be regarded as preliminary.

APPARATUS AND METHODS OF OBSERVATION.

The adoption of accurate hæmometric methods was of course the first requisite in embarking on this inquiry, and the determination of the relative value of the methods in use and of the new ones which it was found necessary to devise for this investigation involved the expenditure of much time and observation in the preparatory stage. I will submit first the results of this preliminary work because they led to the adoption of new modes of observation which should be fully described, but before doing so I will rapidly review some of the methods in present use.

The methods hitherto employed for determining oxy-hæmoglobin are founded on the following principles: (1) the estimation of iron in the ash; (2) the use of the spectrophotometer; and (3) the indication of quantity afforded by depth of colour. The method of determining the iron in the ash and that of the spectro-photometer are wanting in that important quality of practicality which, in the collection of a large body of data, as is demanded by this inquiry, is an absolute necessity. A time-saving yet accurate method was required. The hæmometer of von Fleischl and the hæmoglobinometer of Gowers, both founded on the colorimetric principle, having been most widely accepted in the laboratory and in clinical work, seemed to afford the most promise. But observation led me to doubt whether they afforded readings of sufficient definiteness, reliability, and accuracy for this physiological inquiry. It was therefore determined to ascertain if the colorimetric principle could be employed more advantageously than obtains in these instruments, and the results observed induced me to adopt a new mode of applying that principle.

The methods at present employed for determining the blood corpuscles are (1) examination by the microscope, and (2) percentage estimation by the centrifugal machine. The enumeration method is perhaps on some grounds preferable to centrifugal determination, especially for clinical work, for it enables any alteration in the corpuscles to be observed at the same time. But repeated observation has shown that the method as ordinarily applied by enumerating ten or even thirty squares does not possess that degree of accuracy with which it is usually credited. Though all the necessary precautions have been taken, a series of trials derived from the same mixture of a sample of blood may yield the wide variation of 10 per cent. The possibility of such a large margin of difference as this must render the method totally unreliable for any physiological inquiry, however immaterial it may be for clinical purposes. Extended enumeration—e.g., to 120 squares—will of course average the discrepancies; but it necessarily involves the expenditure of more time and labour than are at the disposal of most observers—especially, too, as physiological work demands the largest possible collection of data and much repetition. It was therefore found necessary to search for a simple time-saving method of hæmocytometric observation which, founded on extended enumeration in the first instance and attaining to the accuracy of it, might be substituted for it. I was fortunate enough to find such a method, which will be described in the next section of this lecture. These preliminary observations demonstrated that the methods in present use for the estimation of the hæmoglobin and the corpuscles are not sufficiently precise for an inquiry into the physiology of the red corpuscle.

THE APPARATUS EMPLOYED IN THIS INQUIRY.[3]

I.—The Hæmoglobinometer.

Before describing the apparatus it is advisable, first of all, to explain the principle that underlies the arrangement adopted, to point out some of the difficulties that have been met with and to describe the steps that have led to the present form of the instrument. A review of all these preliminary matters is essential to a clear conception of the reasons that have determined the adoption of the several details of construction.

The principle followed.—As already stated, the method is founded on the colorimetric principle. But I have modified the applications of that principle as hitherto adopted in the following ways: (1) double transmission of light (or reflected light) is used instead of single transmission; (2) a pure white background is selected on which the solution of the blood and the standard colours rest; (3) the standard is presented as a series of definite gradations; and (4) the colour of the blood solution is compared with that of the standard in camera.

1. *Reflected (or doubly transmitted) light preferred.*—It seems to me that certain advantages are secured by comparing the sample of blood and the standard by means of reflected rather than by transmitted light. These advantages may not at first sight be very obvious, but in this particular mode of observation they nevertheless exist. In the first place, the depth of colour when observed by double transmission of light is nearly twice as much as it is when viewed by single transmission, for the blood solution is seen through a medium of the same colour induced by the incident rays and consequently the colour of the reflected

[1] Lectures I. and II. were delivered on June 2nd and 4th and published in THE LANCET of June 6th and 13th respectively, and Lecture IV. as delivered on June 11th.

[2] Much has already been achieved in this field by the labours of a number of workers, such as Hayem and his pupils Dupérie and Cadet, Grawitz, Schiff, Tietze, Egger, Schüller, Hedin, Cohnstein and Zuntz, Gierlin, Miescher, and Lloyd Jones, among many others too numerous to name individually.

[3] These hæmometric methods were described at the meeting of the Physiological Society held at University College last March.—Proceedings of the Physiological Society, Journal of Physiology, 1886.

Digitized by Google

rays is proportionately increased. Hence a much smaller measure of blood is required under reflected light to produce the degree of colour made apparent by transmitted light, and it is obvious that in a clinical work such a reduction may sometimes prove a distinct advantage, as when 5 c.mm. of blood amply suffice in place of 10 or 20 c.mm. Then, again, light reflected lends itself much more satisfactorily than light only once transmitted to the attainment of uniform physical conditions in the strata of the blood solution and of the standards; and in consequence of the exactly equal adjustments which thus become possible the finest differences in depth of colour become recognisable, and the readings can be made with an exactitude which cannot otherwise be obtained. This outcome of the improved definition has tended to greatly reduce that unavoidable variable element in all observation, the equation of the observer.

2. *The uniform white background.*—The use of reflected light introduces a difficulty in regard to the reflecting background, for this must be uniform, not only in the same instrument, but in other instruments that may be made. The slightest variation in shade or tone of colour must produce discordant readings. In the earlier observations opal glass was selected for this purpose; it was soon discovered that different samples of it were far from invariable in colour. It, therefore, became necessary to select some white substance that could be relied on for uniformity and purity of colour; and dry, finely powdered precipitated lime sulphate was chosen. This substance forms a most delicate reflecting surface and along with the invariable position of it immediately under the blood solution and the standard colours contributes considerably to the exactitude of the readings.

3. *The standard.*—It is a matter of great practical importance in constructing a hæmoglobinometer to determine how the standard should be presented so as to obtain the most definite readings. In von Fleischl's hæmometer the whole scale is formed by a wedge of coloured glass, the depth of colour gradually merging off to the lowest reading; and as the field of view always embraces no less than twenty degrees—i.e., twenty degrees heavier on the right than it is on the left—it is easy to understand, even when the colour of the glass matches that of the blood-solution, that very often considerable uncertainty is apt to exist before an estimation can be made. This mode of presenting and using the standard is obviously faulty. It has been found, however, that all doubt as to the position of any particular sample of blood on the scale is entirely obviated when the latter is split up into a number of definite gradations; and this mode of disposing the standard has therefore been adopted. Each grade becomes a subordinate standard, definitely recognisable from its neighbours, and by means of a simple method, to be subsequently explained, the intervening units are read. Moreover, there exists another reason why each stage ought to be separately standardised and why a mere gradation of the same colour is not only indefinite but is misleading, and that is the specific colour curve of the blood, which will be presently described.

On setting up the standard.—To any one who has not made an attempt of this kind it may seem an easy matter to prepare an imitation of the exact colour of a given percentage of normal blood in water, and thus to accomplish the first step towards the setting up of a hæmoglobin standard. But a few trials will dispel such an illusion and will demonstrate the existence of a number of unforeseen difficulties which are inseparable from the task. The standardising involves two steps: (*a*) the adjustment of colour, and (*b*) the determination of the scale.

A. The adjustment of colour.—In the first instance, following others in the same line of work, experiments were made with carmine or carmine and picro-carmine in a glycero-gelatin basis. After much observation it was finally settled that the closest approximation to the colour of the blood solution was obtained by a combination of carmine, picro-carmine, and hæmatoxylin, the blood and the standard solutions being observed by candlelight in cells having a background of opal glass. The gradations, of course, necessitated that the cells should be quite uniform in depth. After the lapse of some few weeks it was obvious that the colour of the standard was undergoing a change, especially in the lower grades, which were becoming darker and brownish. That led to some experiments on the effect of light on the constituent pigments, and it was found that all of them were unstable when exposed to daylight, and especially to direct sunlight. Of the three constituents, having found that hæmatoxylin was the most fugitive it was excluded. Still the carmines became slowly affected by the exposure incidental to work and observations had to be made in camera. Furthermore, at an early stage of the observations another difficulty was encountered, the explanation of which was not at that time forthcoming. The gradations of the standard were made by diluting the carmine solution of the highest grade to the required degrees. When, however, the blood solution which exactly matched the topmost gradation of the scale was diluted in exactly the same manner, marked discrepancies were apparent between these dilutions and the standard gradations; especially was this the case in the lower half of the scale. They should have agreed, but they did not. Since then a satisfactory explanation of this discrepancy has been afforded by Mr. Lovibond, whose valuable and practical work on colour measurement will presently be referred to. This observer has shown that every coloured substance when progressively varied in concentration or in strata thickness furnishes a colour-curve peculiar to itself—a curve of colour composition which he designates "the absorption colour-curve" or "specific colour-curve."[4] According to this explanation the specific colour-curves of the solutions of the carmines and of the hæmoglobin, though coinciding at a certain degree of concentration diverged below that point, and thus the disparities between them became more and more apparent as the dilution increased. This view of specific colour-curves derives some support from the spectroscope, for it is known that the position and the amount of absorption correspond with the percentage solution of the coloured substance under examination. It therefore follows that no one substance or combination of substances can correctly furnish a percentage series of gradations of hæmoglobin. The uniform tone of colour of the glass wedge of von Fleischl's hæmometer, for example, cannot properly represent the colour of the blood solution throughout the scale. In corroboration of this conclusion we have the observations of Osler, Neubert, and Letzins as quoted by Busch and Kerr.[5] "Osler says that the error in the Fleischl instrument may not be more than 2 per cent. in blood which is nearly normal, but he cites Neubert and Letzins as having shown that in a much impoverished blood the error may be as high as 20 per cent." In order to avoid the difficulties presented by the instability of pigments when exposed to light and moisture, and by the specific colour-curve of the blood it may occur to some, Why not standardise with oxy-hæmoglobin itself? Unfortunately, here again gradual change of colour arises as a bar to its adoption; even though the solution of it is sealed up it becomes reduced and no longer retains the colour of freshly drawn blood. Fortunately, however, all the difficulties which have been encountered in attempting to standardise the colour of the blood have now been resolved, and there no longer exists a necessity to continue the search after a standard which is permanent and which is in accord with the specific colour-curve of the blood, for Mr. Lovibond's practical and accurate method of colour-measurement supplies this desideratum.

In as few words as possible I will endeavour to convey an outline—the merest outline—of Mr. Lovibond's mode of determining colour, and for the necessary details I must refer you to his work on the subject[6] and to various contributions he has made to the societies on the application of his method. This observer has devoted at least twenty-five years to the practical study of light and colour and the outcome of his work is the construction of a system of measuring colour, which is now being adopted in various trades in which colour is a leading indicator of the quality of produce or material and also in some forms of analytical work, such as in the estimation of lead in potable water,[7] of carbon in steel, &c., and in the testing of colour-blindness.[8]

[7] It is claimed that so minute a quantity of lead as one-millionth of 1 per cent. may be detected by Mr. Lovibond's method.

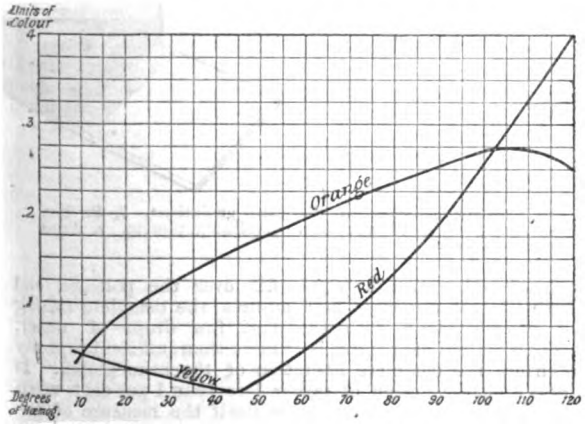
[8] When I set up my standards with Mr. Lovibond's standard colour-glasses I was not aware of any practical hæmometric work having been done with Mr. Lovibond's tintometer. I have since ascertained that Dr. Copeman has been using it for this purpose during the past few years with much satisfaction.

Digitized by Google

The matching and the measurement of colour are effected in a camera apparatus (the tintometer) by the aid of three sets of definitely graded glasses, one for each of the dominant colours, red, yellow, and blue. The graduations are of equivalent value in all the sets, the test of equivalency being the destruction of all colour and the production of grades of neutral tint by combining the equivalent glass of each set, the observation being made with white light. When the equivalent glasses of two of the dominant colours are combined the three subordinate colours are produced—namely, green, blue, and violet. All other shades and degrees of colour are obtained by combining the glasses of the dominant colours in non-equivalent proportions, so that any colour can be accurately matched by them. The colour scales are made up of units and decimal parts of a unit down to 0·01, which is the lowest fraction of a unit that can be differentiated by the vision. The fixing of the unit has necessarily been arbitrary, as has, indeed, been that of any standard measure, such as the mass of distilled water which has been chosen to represent a gramme, &c. Inasmuch as the unit chosen complies with the requisites of a standard—being uniform, recoverable, and arbitrary—it should be accepted as such; the actual dimensions of it, so long as they serve the practical ends in view, are of no importance. Of course, the correct grading of the glasses from the original standards is essential to the success of the method, and this is, I believe, effectually attained by an elaborate system of cross-checking by a series of trained matchers. These graded glasses of determined value provide a numerical quantitative measure of any colour to be gauged, and they enable the measurements made by them to be recorded, so that the colour thus measured may be reproduced at will or may be preserved indefinitely.

With the view of fixing the blood standards I had the advantage of working in the colour laboratories at Salisbury and of obtaining the valuable assistance of Mr. Lovibond and of his well-trained staff. Samples of blood taken at different times of the day were diluted with distilled water and standardised by my carmine standard of the highest grade. The colour of the different percentage dilutions placed in the blood-cell was then carefully matched and determined by the graded glasses, finely powdered precipitated lime sulphate forming the background of the cell and of the glasses, and the estimations were made by aid of the camera tube presently to be described. The standard gradations of the apparatus were thus settled and they form the two specific colour-curves of the blood—one determined by uniform candle-light and the other by white daylight. Here are the two sets of standards, and you will observe that the difference between them is so remarkable that it is obvious that hæmoglobin cannot be estimated by the same standard used indifferently in the two kinds of light. The colour-curves (Figs. 14 and 15) are made by entering the colour units on the side of the diagram to form abscissæ with the standard gradations which appear at the foot. In daylight (Fig. 14) it will be observed that the

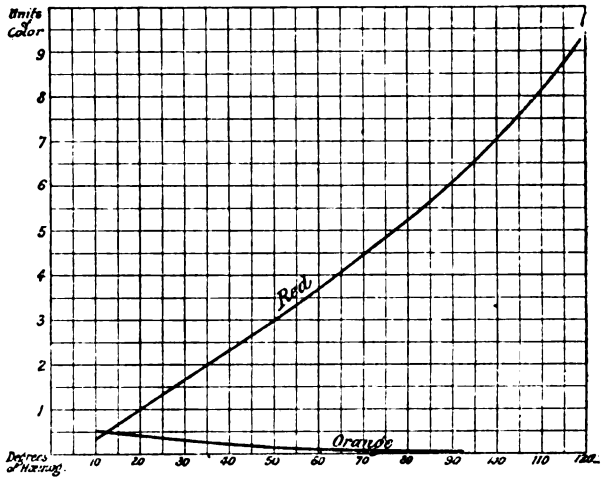
FIG. 14.



Specific colour-curve of blood. Daylight.

specific colour-curves of the blood are madeup of varying proportions of red, orange, and yellow. In the lower percentages (10, 20, 30, and 40) red as a separate colour does not exist; it is only present in combination with yellow as orange, which is made up of equivalent proportions of each. In these lower gradations the place of red is taken by yellow. Between gradations 40 and 50 yellow dies out, and then red appears and progressively increases until at the highest grade it is the dominant colour. In these daylight gradations the curve of orange is the predominant one, though it begins to die out in the higher part of the scale. In candle light (Fig. 15) the colour-curves are quite different and are less

FIG. 15.



Specific colour-curve of blood. Candlelight.

complicated. Red is predominant throughout except at the lowest grade, where it is subordinated to orange. From this point upwards orange gradually diminishes and vanishes entirely at 90, and then pure red distinguishes the highest grades. The remarkable difference between the colour-curves furnished by the two kinds of light is doubtless due to the preponderance of yellow emitted by the candle flame.

The standard colours and the gradations having been duly measured and determined there still remains a further adjustment to be made. It is found that the solution of blood possesses in a remarkable degree the quality of colour-purity or brilliancy—a quality which is distinct from colour-depth and colour composition, for it remains after these have been duly matched.[9] Inasmuch as this property of the blood may prove a distracting element with some observers, and may possibly lead to errors in observation, it is important that it should be eliminated from the views, especially as Mr. Lovibond's system of graded glasses supplies the remedy. It is met by using one of the lower grades of the blue glasses as a cover-glass to the blood cell; and it has been found that this adjustment does not disturb the correct reading of the hæmoglobin.

B. The determination of the scale.—The hæmoglobinometers hitherto used merely furnish estimations of hæmoglobin which are relative to a certain quantity believed to represent the proportion present in the blood of man in health—a quantity which is, moreover, undetermined and therefore unknown. Inasmuch as it will be shown presently that the blood of healthy subjects is not quite so definite and invariable as it is usually believed to be, it would seem to be more satisfactory to be able to quantitatively determine the amount of oxy-hæmoglobin present in each sample of blood tested than to rely entirely on an indefinite arbitrary standard. The quantitative equivalence of the scale in oxy-hæmoglobin has therefore been determined. The blood of the dog was preferred to that of man for this purpose, because the process of separation is comparatively easy, while in the latter it is in many respects unsatisfactory. Great difficulty was, however, encountered in obtaining a pure product, which retained the exact colour of freshly-drawn blood, so that accurate estimations of it could be made. Ultimately this result was attained by determining certain percentages of the moist crystals

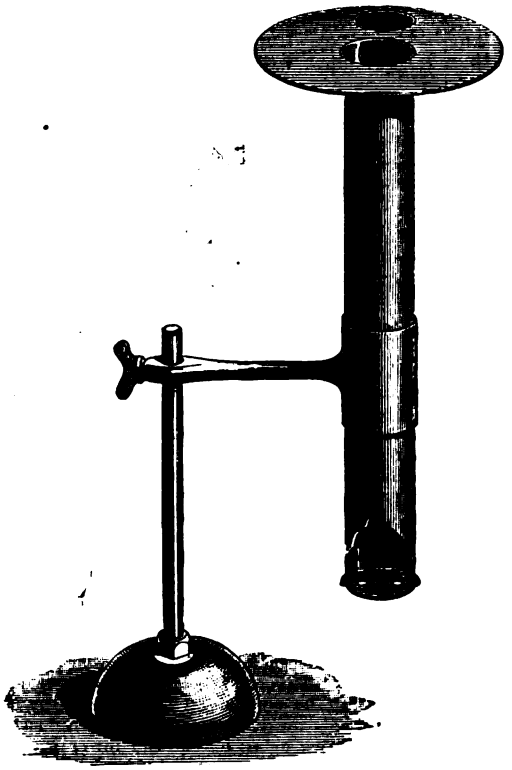
[9] Mr. Lovibond tells me that this fact is occasionally observed in the matching of other substances, notably some of the aniline dyes.

Digitized by Google

and afterwards correcting for the water.[10] Each degree of the scale is equivalent to 0·155 per cent. oxy-hæmoglobin in the sample of blood tested, therefore 100 degrees represent 15·5 per cent; and determinations above or below that point will require the addition or subtraction of 0·155 per cent. for each degree. It may be mentioned that Preyer[11] gives the average percentage of hæmoglobin for women as nearly 13 and for men 14. Dr. Augustus Waller[12] has found 17 per cent. in the blood of the dog. Observation has shown that the mean percentage of hæmoglobin present in the blood of man in health containing 5,000,000 corpuscles per c.mm. (or 100 per cent. of corpuscles) is represented by 100 degrees.

4. *Observation to be made in camera.*—From the first it was found that a reliable judgment between the two colours of the blood solution and of the standard when closely approximated could not be formed unless the colours were observed through a tube so arranged as to shut off all side lights and other causes of distraction. The best results were obtained by using a long tube (Fig. 16) resembling a microscope tube,

FIG. 16.



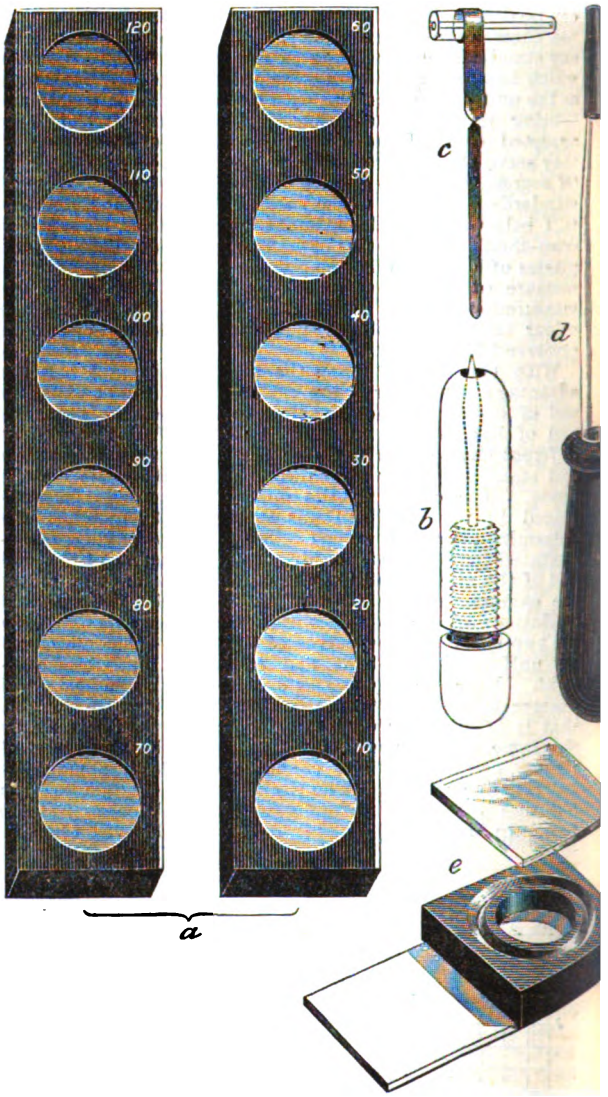
The Camera Tube.

blackened inside, and presenting below two circular holes of 5 mm. in diameter, so as to include only a small but equal area of each of the colours to be compared, and encircled above by a diaphragm or collar which shields the eyes from the direct rays of the candle flame. The tube is held in a vertical position over the colours by means of a side-stand, and it may be adjusted to the required height so as just to avoid any shadow which may be cast by the rays of the candle flame impinging on the lower end of it. A piece of green glass is let into the collar, for it was found that when the sense of colour appreciation was impaired from any cause, such as long and frequent observation, it was restored or was even intensified after looking at the candle for a few seconds through the green glass (Fig. 16).

The apparatus.—A few words remain to be said on the parts of the apparatus and how to use them. These are: (1) an automatic blood measurer; (2) a mixing pipette; (3) the blood cell and cover glass; (4) the sets of standard gradations; (5) the riders; (6) the camera tube; (7) the light; and (8) a bottle of antiseptic fluid, the prickers, needles, and thread.

1. *The automatic blood measurer* (Fig. 17 *c*) has a capacity of 5 c.mm. and fills readily by capillary attraction. It differs from the fragile capillary measurer hitherto used in being made of stout glass and therefore serviceable, in being larger and more manipulable, and in having the end which is presented to the blood well polished, so that all traces of blood can be entirely removed from it by the finger. The bore is dried out before an observation by passing a needle threaded with darning cotton through it. The handle is useful for stirring together the blood and water in the blood-cell. 2. *The mixing pipette* (Fig. 17 *d*) is provided

FIG. 17.



The hæmoglobinometer. *a*, Standard gradations. *b*, Pricker. *c*, Automatic blood measurer. *d*, Mixing pipette. *e*, Blood cell and cover.

with a rubber nozzle which fits over the polished end of the blood measurer and ensures the complete rinsing out of the blood with the first few drops of water. 3. *The blood-cell* (Fig. 17 *e*) is of more than sufficient capacity to ensure the complete liberation of the hæmoglobin. It yields a blood-solution of rather less than 1 per cent. when filled level with the rim. It is itself the measure of the amount of water to be added and it is quite easy to fill it accurately. 4. *The standard gradations* (Fig. 17 *a*) are arranged as circular discs in two slabs—six in each—and they represent the divisions of 10 degrees of the scale, from 10 to 120 inclusive. 5. *The riders* provide for the reading of the

[10] In carrying out this part of the work I must express my indebtedness to Mr. Moore of the Physiological Laboratory of University College for his valuable aid.

[11] Die Blutkrystalle.

[12] An Introduction to Human Physiology, 1893, p. 35.

Digitized by Google

degrees intervening between each of the standard gradations. When they are used the slip of colourless glass is placed over the cover of the blood-cell so as to balance the effect of the mere layer of glass of the rider which is laid over the standard. Two sets of riders have been arranged — one suitable for physiological observation, to ensure the finer readings—e.g., of one degree; and the other, sufficient for ordinary clinical observation, to enable the observer to determine differences of 2½ degrees. For the reading of the units nine riders are required which are grouped into three slides. It should be premised that the value of the riders is neither the same in the two standards required for candle-light and daylight nor in the upper and lower halves of either standard. This want of uniformity arises from the differences of the specific colour-curves in the two standards and in the two portions of each. In the six lower grades of both standards the value of each rider is double that in the upper six gradations. In the transition grades—the lowermost of the upper half and the uppermost of the lower half—this rule does not quite accurately apply, but inasmuch as the departure is constant in all observations, and is, moreover, slight, it may be disregarded for the sake of simplicity in using the riders. The daylight standard is less adapted to the finer readings than the candle-light one, because the value of each rider when used with it is doubled—i.e., number one rider becoming equal to 2 degrees in the upper half of the scale and 4 degrees in the lower half. Therefore, the candle-light standard is preferable for such readings, and when it is used each rider has an equivalent value in the six stronger grades—1=1 degree, and a double value in the six weaker grades 1 = 2 degrees. For ordinary reading one rider only is used—namely, that which is equivalent to 5 degrees in each slab of the standards. Therefore, each set of six standard gradations, whether for candle-light or daylight, has its own rider. When the blood solution is deeper in colour than any particular standard gradation, but is overstepped by the rider, the mean between the two may be taken as the reading, and the same rule will apply when the colour of the blood is higher than the rider, but is not so high as that of the next standard grade above. Hence this single rider may be made to provide readings of 2·5, 5, and 7·5. 6. *The camera tube.* It had already been pointed out that observation should only be made through a camera tube, and the one which has been employed throughout this inquiry has been described. It is, however, perhaps somewhat elaborate for the ordinary course of clinical observation; therefore, one of simpler construction is provided which may serve this purpose and, being collapsable, will pack into a small compass with the other parts of the apparatus. 7. *The light.* For observation by artificial light it has been found that the small-sized wax candles known as Christmas candles are the most satisfactory in affording the most suitable intensity of light, and one, moreover, which is sufficiently uniform. The position of the candle is important; it should be such as to shed an equal light on the blood-cell and the standard, and also such as to furnish a high light, so that the flame should be three or four inches above the cells. The distance must be regulated by the observer, who will soon learn how to adjust it to the best advantage, so that he may match the colours with greatest certainty and accuracy. The actual distance does not affect the reading; but when the candle is placed too near the points of observation the illumination becomes too strong and is somewhat distracting, especially when the lower grades are under observation, which require less degrees of light than the higher. In daylight all colorimetric modes of estimating hæmoglobin are less or more unsatisfactory, for they require a uniform degree and kind of light which cannot always be obtained when daylight is resorted to. The colour of the blood solution varies in a marked degree, according as the light is blue or white, or is feeble or waning, or is strong. Therefore, the candle-light standards are to be preferred as being always available with a uniform light. 8. *The antiseptic fluid and pricker.* Before every observation the pricker should be dipped into an antiseptic solution that will not corrode the metal, and a little of the solution should be smeared over the part to be pricked. I prefer a mixture of equal parts of carbolic acid and spirits of wine.

How to make an observation.—The bore of the blood-measurer is first of all dried out by passing through it a needle threaded with darning cotton, and then the polished point is presented to the drop of blood which flows, under the least possible amount of pressure, on pricking the inner side of the pad of the finger or near the root of the nail. Care must be taken to see that the pipette is really quite filled, and if it has been necessary to re-apply it to the drop it should be observed whether there is a break in the column of blood. Any blood adhering to either end must be carefully wiped away with the finger. The rubber nozzle of the mixing pipette, charged with water, is adjusted over the polished end of the pipette, and the blood is washed into the blood-cell by pressing through the water drop by drop. The handle of the pipette is then used as a stirrer, and the further additions of water are made to impinge on it, for it serves to graduate the size of the drops required to accurately fill the cell. It is in this way quite easy to do this when the observer catches the reflection of the light on the surface of the fluid. A final thorough mixing with the handle will be required, and perhaps another slight addition of water may be necessary to secure a level filling. The cover-glass is then adjusted, when a small bubble is sure to form, a sure sign that the cell has not been overfilled. The blood cell is then placed by the side of the standard gradations and the eye quickly recognises its approximate position on the scale. Then the camera tube will more accurately define it. If it is found that the blood solution is matched in depth of colour by one of the standard grades the observation is of course at an end, but if it is observed to be higher than one gradation, but lower than that above it, the blood-cell is placed opposite to the former and the riders are added to complete the estimation.

II.—The Hæmocytometer.

The principle followed.—The method is based on the following facts:—*a.* When a candle-flame is viewed through a glass tube containing water a transverse line of bright illumination is seen, consisting of closely packed, minute images of the flame produced by the longitudinal fibrillation of the glass. In the process of drawing out the tube becomes minutely corrugated or fibrillated in the direction of its axis. The corrugations are extremely small, but they are easily observed when a tube is held before a flame and the structure of the glass is examined by a pocket lens, when the corrugations are seen to produce alternate bright and shaded lines disposed in the vertical direction. Each corrugation acts as a lens, hence the horizontal line made up of a congeries of images of the flame. *b.* When some fixing fluid (such as Hayem's, or a solution of potassium ferrocyanide, sodium chloride, &c.) is added to blood the mixture presents a certain degree of opacity according to the amount of blood or of the fixing fluid. *c.* The opacity thus produced completely shuts out of view the illuminated line, until, on diluting further, a definite point is reached, when it can just be detected as a delicate streak of light across the tube—the dawn, as it were, of the bright minute images of the flame seen when the opacity is absent or is further reduced. Repeated observation has shown that the development of this delicate horizontal line by dilution with the fixing fluid selected is a very sensitive indicator of the percentage of the blood corpuscles. This was shown in various ways; for example, by the measure of the fixing fluid required to bring the line into view being always in proportion to the different quantities of the same blood experimented with, and therefore in proportion to the number of the blood corpuscles present at each observation.

The apparatus.—The principle just described has been made available for determining the percentage of the cellular elements of the blood by mixing a definite measure of the blood with Hayem's solution in a graduated flattened tube. The apparatus consists of (1) a graduated flattened tube; (2) an automatic blood measurer; (3) a mixing pipette; (4) a candle; and (5) a bottle of Hayem's solution.

1. *A flattened tube* (Fig. 18 *c*) has been adopted because it was found that a round tube of such a diameter as to furnish the required degree of opacity will only provide a sufficiently wide scale when a much larger quantity of blood is taken than is generally used for observation of the blood; whereas when the observation is made through the long diameter of a flattened tube it is not necessary to use more than 10 c.mm., and the scale is lengthened in proportion to the reduction of the lateral area. A tube of 15 mm. in the long diameter and 5 mm. in the short diameter provides a good workable scale of 12 centimetres for the determination of 125 per cent. of corpuscles. The divisions of the scale

Digitized by Google

represent 2 per cent. and they are sufficiently apart to allow the eye to read 1 per cent. or even less. 2. *The automatic blood measurer* (Fig. 18 *a*) is the same in construction as that used in the estimation of hæmoglobin, only its capacity is greater. 3. *The mixing pipette* (Fig. 18 *b*) is provided with a rubber nozzle which fits over the polished end of the blood measurer. 4. *The candle* should give a small flame, for that furnishes a more defined line than is obtained from a large flame. The small-sized wax candles known as Christmas candles are the best. A reduced gas-flame also answers perfectly well. 5. *Hayem's Solution.* It was found that each kind of fixing fluid furnishes its own scale—Hayem's[13] was selected as the most satisfactory. The chief

advantages of it are that it is cleanly to use, that the corpuscles are less affected by it than by other fixing fluids and may be examined under the microscope after the observation has been made without fear of material changes, and that the reading undergoes no variation after the lapse of many hours—e.g., twelve—so that the blood may be washed into a tube and the observation may be made later if more convenient. It may be suspected, however, that the proteids of the plasma may be precipitated by the mercuric chloride present in Hayem's solution, and thus a variable addition may be made to the opacity caused by the corpuscles. This point has been carefully tested with the result that it does not present a source of fallacy. 50 c.mm. of the plasma separated from a blood containing 100 per cent. of corpuscles were washed into the tube with Hayem's solution, but only as far as the 20 per cent. mark, so that the solution contained twenty-five times as much of the proteids as would be contained in 10 c.mm. of the blood diluted to the 100 per cent. mark; and there was apparent the merest haze, so small, indeed, that it could not possibly be determined. It is therefore obvious that the proteids of the plasma do not increase the opacity induced by the fixing of the corpuscles by means of Hayem's solution. The determination of the scale was made by the enumeration method extended to 120 squares applied to the blood of normal man. 100 per cent. presents the generally accepted standard of 5,000,000 per mm.; therefore, 80 per cent. is equivalent to 4,000,000, &c.

The method from the physiological standpoint.—The white corpuscles in a state of health do not affect the readings. The proportion of 1 white to 500 red, or one-fifth per cent., is equivalent only to one-tenth of one of the smallest divisions on the scale, and this is unreadable. So that were the white corpuscles to increase to 1 in 250, such a rise would not appreciably affect the reading of the red corpuscles. The normal variation of the white corpuscles therefore may be safely neglected.

The method from the clinical standpoint.—I have employed this method in clinical observation and found it not merely simple and time-saving, but useful. Apart from the leucocythæmic condition the white corpuscle is not a source of interference. A distinction should be made between the method of enumeration and a volumetric method like this or like that of centrifugal separation, for the aim of the former is to determine the individual corpuscle irrespectively of size, whereas that of the latter is to refer the collective volume of the corpuscles to that of the normal standard. Pathologically it is important to ascertain the size of the red discs, and, therefore, the microscopical inspection of the fluid is a useful addendum to the observation. So long as the average size of the corpuscles is unaltered the method is comparable with that of enumeration, on which it is founded. But inasmuch as that in certain cases may vary—e.g., the microcytes of chlorosis[14] and the macrocytes of pernicious anæmia—the method should, strictly speaking, be regarded as a volumetric one like that of centrifugal separation. It is highly probable that it is clinically advantageous to be able to estimate the corpuscles in any case by comparing them with the normal percentage volume employed as a standard. Such an estimation will probably afford a true gauge of the aggregate corpuscular value of the blood; for it is the collective capacity of all the corpuscles, whatever their size, that is measured by the physiological standard.

The mode of observation.—The pipette, previously dried out by passing through it a needle threaded with darning cotton, having been accurately filled, the slightest traces of blood on the outside of the glass either at the ends or on the side are very carefully wiped away with the finger. The rubber nozzle of the mixer filled with Hayem's solution is then applied over the bevelled end of the pipette and the blood is thoroughly washed into the flattened tube. The amount of the fixing fluid to be used in the first instance will be roughly suggested by the previously made hæmoglobin estimation; if this afforded from 90 to 100 per cent. or more the dilution may at once proceed to the 80 per cent. mark, but if it yielded a lower figure the preliminary dilution should be smaller. The contents of the tube are then uniformly mixed by inverting the tube a few times with the thumb over its mouth, care being taken on removing the thumb to draw it over the lip of the tube so as to restore as much as possible the fluid adhering to it. This procedure should of course be repeated after every addition of the diluting fluid. The observation is made in a dark room or in a darkened room free from cross lights. The observer stands 10 ft. from the flame. In making the observation it is important to shut out as much as possible the diffused light of the candle. The most satisfactory way to do this is to place the lower end of the tube, with its long diameter in a line with the candle, in the concavity between thumb and forefinger, so as to make as it were a frame for it, and then to bring this part of the tube quite close to the eye (Fig. 16*d*). The observer must look out sharply for the first appearance of the transverse line of light which dilution brings into view, and the earliest indications are obtained by turning the tube on its axis when the

[13] The formula is as follows: hydrargyri perchloridum, gramme 0·5; sodii chloras, gramme 1·0; sodæ sulphas, grammes 5·0; aqua destillata, 200 c.c.

[14] So far the only discrepancy which has been met with between this method and that of enumeration has been observed in chlorosis, in which when heavy microcytes exist the readings of the tube are somewhat reduced.

Digitized by Google

line will be caught first of all on the side. The fluid is then added point by point until the line is just apparent, when the long diameter of the tube is directed to the flame. This indication is a very delicate one, and requires a little pains at first in order to clearly recognise it without overstepping the necessary dilution, which of course brings it more definitely into view. The first difficulty is the only one, for when the earliest appearance of the line has been once observed it cannot fail to be afterwards recognised.

There is, as a rule, a rather rapid transition between the total absence of the line quite across the tube and the presence of it. Most observers will find no difficulty in defining their readings by stages of half a division—i.e., 1 per cent. It is not necessary to hurry over each observation after adding more fluid and mixing up, for the opacity remains uniform for several minutes.[15]

The method followed in collecting data.[16]—The blood of a large number of healthy subjects belonging to the average well-nourished class has been observed by these new methods with the view of ascertaining the influence of age, sex, and other general physiological conditions on the percentages of the corpuscles and hæmoglobin; but I regret that the limited time at my disposal does not permit me to use this material just now. These rapid hæmometric methods have also been applied pretty widely to clinical work in order to determine the value of such observation in the general run of cases, whether these presented the ordinary signs of anæmia or not. The data thus obtained have shown that an extension of direct observation of the blood is likely to yield useful results, for ofttimes it has demonstrated the existence of moderate degrees of anæmia which had escaped ordinary clinical observation and which was sufficient to maintain a condition of low resistance and of instability of health apt to be referred to denutrition of the nerve centres rather than to that of the blood; and it has, moreover, often shown that anæmia was not present when the general symptoms suggested it. Furthermore, it has afforded evidence of the not uncommon occurrence of an apoplasmic state of the blood which is worthy of further observation and study. I again regret that the shortness of the hour admits not of more than mere passing references to the clinical side of this enquiry. A large portion of the physiological data has been derived from a long series of observations on the blood of two subjects, A. and B., the former twenty-seven and the latter fifty-four years of age. In both cases the corpuscles and hæmoglobin have been determined night and morning for over seven months. Besides this long series of consecutive observations innumerable others have been made in order to determine the effects of exercise, of digestion, and of various other physiological conditions on the percentages of the corpuscles and hæmoglobin. The most important part of the physiological data was collected under the conjoint observation of my co-worker and myself while the subjects were placed in exactly the same physiological conditions. The results were not recorded until cross-checked by each of us. There was rarely any discrepancy between us as to the readings; and when any did arise it was trifling and was adjusted to our mutual satisfaction. This fact shows two things: first, the advantage of two observers working together in making such observations as these, and, secondly, the smallness of the personal equation to be attached to the methods employed. Besides the special experiments referred to, a series of consecutive hourly observations was made during nearly three weeks in which the ingestion of food and liquid and the output of urine were noted. Observations have also been made on animals. In the first instance, dogs were used; but it was found that the thick hide renders these animals much less suitable for this kind of observation than man. Some satisfactory and reliable observations were, however, made on the blood derived from the veins on the outer surface of the rabbit's ear showing the range of daily variation and the effects of oxygen and ether.

The normal reading of the corpuscles and hæmoglobin and of the worth of the corpuscles.—One hundred per cent. normal corpuscles should contain hæmoglobin which reads as near as possible 100 per cent., so that when the latter is divided by the former the unit obtained will represent the normal mean value of the corpuscles in hæmoglobin. The attempt, however, to bring the two percentages into accord has not been by any means an easy task because of the wide physiological variation which is continually taking place in both. The present readings cannot claim to be more than an approximation derived from a large number of observations in healthy subjects. The quotient obtained has been aptly denominated by Dr. Archibald Garrod "the worth,"[17] and by Dr. Haig "the blood decimal."[18] In health the average variation extends from 0·95 to 1·05. It will be found that the actual readings of the corpuscles and hæmoglobin in health, whether in the same subject at different times or in different individuals, is a pretty wide one. In men the average normal range embraces from 95 to 105 per cent. and in women from 90 to 100 per cent. In either sex, and particularly in men, a reading below 85 per cent., especially when the hæmoglobin percentage is still lower, is as a rule distinctly subnormal. The determination of the corpuscles or of the hæmoglobin alone is of but little physiological or pathological value.

Normal variations in the proportions of the chromocytes and hæmoglobin.—Six hundred and forty-nine consecutive night and morning observations[19] in subjects A. and B. have furnished some interesting results in regard to the variations of the red corpuscles in their relations to the hæmoglobin and the plasma which occur in the course of twenty-four hours, from day to day, from week to week, and from month to month. The data derived from each subject corroborate those furnished by the other.

Night and morning variations in the percentage of the hæmoglobin.—The most striking fact is the rise during the night and the fall during the day. Taking the figures furnished by both subjects the rise took place in 90·5 per cent. of all the morning and the fall in 88·4 per cent. of the total evening observations. 5·1 per cent. of the morning and 4·4 per cent. of the evening observations were equal. In 100 observations the night rise of hæmoglobin was observed 90½ times and the night fall only 4½ times; and the day fall occurred 88½ times, while the day-rise took place only 7 times. In both subjects the average night rise was 7·2 per cent., and the average day fall was 7·4 per cent., and the maximum rise was 20 per cent. and the maximum fall 21 per cent. It was observed that when the hæmoglobin fell in the night and rose in the day the average rise and fall were much less than when it followed the rule of rising in the night and falling in the day, for then the average night fall was 2.1 per cent. as against 7·2 per cent. night rise, and the average day rise 2·7 per cent. against 7.4 per cent. day fall.

The night and morning variations in the percentage of the corpuscles was observed to be similar to those of the hæmoglobin, only they were not quite so decisive, in both subjects the morning rise and the evening fall being less frequent. The day fall was much more frequently observed than the night rise, the frequency of the former being 74·9, while that of the latter was 68·5 per cent. Probably this difference indicates the influence of fluids taken during the waking hours. Moreover, the observations show that the corpuscles vary less than the hæmoglobin; for the difference between the night and morning and between the morning and evening observations is much smaller and the number of the observations in which they do not vary at all is greater. Whereas the average variation of the hæmoglobin in twenty-four hours is 7·3 per cent. that of the corpuscles is not more than 4·3 per cent., and whereas the hæmoglobin was without variation in 4·8 per cent. the corpuscles were constant in 8·7 per cent. of the total observations in twenty-hours. If it be accepted that the actual number of corpuscles in the same healthy subject remains pretty constant throughout twenty-four hours, it follows from these facts, that though the plasma is distinctly variable at different times during this short period, it is less variable than the hæmoglobin. These night and morning

[15] The corpuscles themselves and the uniform distribution of them may be observed as separate particles when, on turning the short diameter of the tube towards the flame, the contents are examined by means of a pocket lens. As some may wish to use this apparatus, I hope that the Tintometer Company, 6, Farringdon-avenue, E.C., after settling certain technical details to secure uniformity of production, will supply it.

[16] In the collection of the physiological data I have had the able coöperation of Dr. Edgecombe of Harrogate. Our conjoint results have not yet appeared.

[17] Transactions of the Royal Medical and Chirurgical Society, vol. lxxv., p. 191.

[18] Uric Acid, third edition, 1896.

[19] Over 400 observations have been excluded because they were made before the methods of observation were quite settled; they, however, afford the same conclusions as those yielded by the observations which were accepted. Therefore these conclusions as to normal variations of the corpuscles and hæmoglobin may be said to be derived from over 1000 observations. [Since this was written 150 further night and morning observations have been made which afford the same results.]

Digitized by Google

variations of the corpuscles and hæmoglobin are in keeping with Lloyd Jones's observations on the specific gravity of the blood, for this observer found that, as a rule, it was higher in the morning and lower at night.[20]

Night and morning variations of "the worth" of the chromocytes.—The data furnished by the night and morning observations show that in 74 per cent. of the morning observations "the worth" rises in the night, and in 73 per cent. of the evening observations it falls in the day; the average rise and fall (0·061 and 0·057 respectively) being nearly equal, but with a slight preponderance in the former. This average gain over loss of hæmoglobin probably provides a reserve for variable calls upon it, when at times it is found to be above or below the mean. The subjects A. and B. have furnished data which entirely coincide in the inferences to be drawn from them in regard to the formation and disappearance of hæmoglobin. The influence of sleep apart from that of mere rest on the formation of hæmoglobin has not been ascertained. Inasmuch, however, as observation has not shown that the sleepless are particularly low in their "blood decimal," though perhaps further observations are required on this point, it is probable that the nocturnal rise of hæmoglobin is mainly due to rest—to the abeyance of functional activity and work. Opportunities have been afforded of observing the effects of residing in town and country on "the worth." During the period of observation A., who lives in the country, spent three weeks in London, and B., who lives in town, was in the country throughout September, October, November, and May. In neither case did the blood decimal fall in London, and B.'s was actually higher during the five months he lived in town than it was in the four months he spent away from it. From these, and from other similar facts which have been observed, it is concluded that town life is not quite so unfavourable to "the worth" among the well-fed class as is usually supposed.

Inasmuch as the recent investigations of Neuski, Sieber, Schunck, and Marchlewski have drawn attention to the remarkable similarity between the chemical and spectroscopic properties of some of the derivatives of hæmoglobin and chlorophyll,[21] it may be worthy of remark that though these organic pigments produced by animal and vegetable life very closely approximate at certain points, they seem to be developed under widely different physiological conditions, hæmoglobin being generated during systemic rest and chlorophyll being the product of chemical activity having a complicated dependence on light.

The day curve of variation is marked by subsidiary curves of fall and rise due to the digestion and absorption of food and by a steep decline which marks the last third of the waking hours. The data obtained before breakfast and lunch are, as a rule, of nearly equal value.

Periodical variations.—The morning (fasting) observations, taken at a time when the blood is least influenced by food, fluids, and work, show that variations are apparent from day to day, from week to week, and from month to month. The average daily, weekly, and monthly variations in corpuscles and hæmoglobin are close upon 3, 2, and 2 per cent. respectively. The weekly and monthly corpuscle value during the past three months has in both subjects steadily risen, especially in subject A.; but it is doubted if the data furnished by him in regard to variations in periods extending beyond one day are to be relied upon, for before his remarkable rise in corpuscle value took place a trace of lead was detected in the drinking-water, although he afforded no signs whatever of lead poisoning. This leads me to remark that the extended use of hæmometric observation during last summer enabled me to detect several cases of lead poisoning which had escaped ordinary recognition; and in every one of these cases the source of the poisoning was discovered. The consecutive observations extending over seven months do not provide data sufficiently extended to enable any reliable conclusion to be formed as to the occurrence of cyclical or seasonal changes in the blood. In A.'s weekly chart of hæmoglobin there are apparent six very regular and pronounced rises and falls, which point to periodicity in the formation and destruction of hæmoglobin. This may, however, be merely accidental; and no such cyclical variation appears in the chart of the older subject, B. Menstruation has not yet been sufficiently observed from this standpoint to warrant any definite statement of results.

Variations in the corpuscles, hæmoglobin, and corpuscular value in animals.—120 daily observations in dogs and rabbits have shown that the daily variations of the blood in them are quite as great as in man; even though these animals were leading the quiet and unvaried life of laboratory confinement. This fact derived from the rabbit is instructive; for the blood in this animal being taken direct from a vein (of the ear) shows that the observed variations are due to actual changes in the blood itself and cannot be ascribed to differences in the amount of lymph which may be stored in the tissues.

[20] Journal of Physiology, vol. viii.

[21] According to Schunck and Marchlewski the anhydride of hæmatoporphyrin, a derivative of hæmoglobin, differs from phylloporphydrin, a derivative of chlorophyll, simply in having three atoms more of oxygen; and, moreover, both these derivatives present the same coloured solution and practically identical absorption spectra. "That the two series of derivatives, that of chlorophyll and that of hæmoglobin, each playing an important part in the vegetable and animal organism respectively, should so closely touch at one point is certainly a remarkable circumstance. In another respect the two series seem to be related. It is well known that the colouring matter of the blood is a derivative of pyrrol. This appears to be the case with chlorophyll also."—Contribution to the Chemistry of Chlorophyll, No. 7, Proceedings of the Royal Society, January, 1896.

The Ingleby Lectures

ON THE

MECHANISM OF BINOCULAR VISION AND THE CAUSES OF STRABISMUS.

Delivered at Mason College, Birmingham, on June 10th and 17th, 1896,

BY PRIESTLEY SMITH, M.R.C.S. ENG.,

OPHTHALMIC SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM; LECTURER IN OPHTHALMOLOGY AT MASON COLLEGE, BIRMINGHAM, ETC.

LECTURE I.

GENTLEMEN,—The term "strabismus"—or, in plain English, "squint"—denotes that condition in which a person looks straight with one eye at the object at which he wishes to look, while the other eye turns in some other direction. Used broadly it covers deviations of the eye of many kinds arising from many causes. In studying the causes we have to look beyond the mechanism of the orbit to the subtler mechanism of the brain; to take into account the influence of hereditary and congenital peculiarities as well as that of accident and disease of many kinds, and especially to regard the process of natural education by which the rudimentary faculties of the newborn child are gradually brought to perfection. The subject, therefore, though belonging specially to ophthalmology, has many points of contact with other branches of medicine and particularly with the diseases of children, and its discussion will not be entirely foreign, I think, to the purpose which the generous founder of the Ingleby Lectureship had in view.

Strabismus involves two disadvantages—disfigurement and disability. Facial expression depends much upon the action of the eyes. We establish a complete sense of mutual understanding and sympathy with another person only when our eyes are met by his or hers; when one eye only meets our own, while the other wanders off elsewhere, the sense of reciprocity is imperfect. But there is no need to insist on this; caricaturists and writers of fiction have done so too much already and have often associated obliquity of the eye with obliquity of the morals, for which there is no justification whatever. Still, it is right to say that those who through indifference allow a child to grow up with a squint which might have been avoided are handicapping him heavily in the race of life. I have heard of one case only, related to me by Mr. Bickerton, in which a squint was an advantage. A low comedian with an extreme divergent strabismus applied to him for treatment and was cured by operation. Not long afterwards he came back to say that the loss of his squint had proved a great misfortune, for whereas formerly his mere appearance on the stage would always provoke a laugh he had now to work hard even to raise a smile. But strabismus is not merely a matter of appearance. Every deviation of the eye, however slight, involves a loss of true binocular vision, and it is in this complex disturbance of function that the chief interest of

Digitized by Google

the subject lies. To-day I shall ask you to consider the mechanism on which normal binocular vision depends—not its details, but its general arrangement and purpose. In my second lecture I shall attempt to point out the various ways in which this mechanism may be disturbed.

Speaking broadly, and disregarding for the moment the functions of the cerebellum, we may say that the organs through which we deal with external objects are controlled on each side of the body by the opposite side of the brain. For example, the right hand moves and feels, and the right ear hears, by virtue of its connexion with the left half of the brain. How is it with the visual apparatus? Let us

FIG. 1.

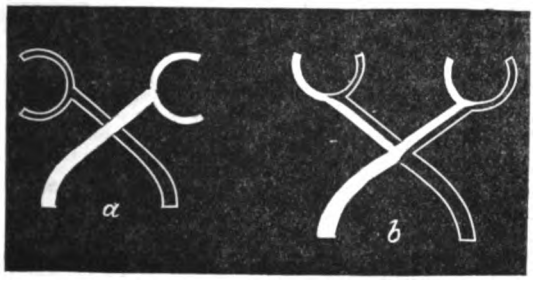

Diagram showing arrangement of retinæ and optic nerves in (*a*) fish and (*b*) man. The solid white portion is the visual organ for the right side.

look for a moment lower down in the animal scale. In the cod-fish the eyes look directly outwards to the right and to the left. (Fig. 1, *a*.) The right eye is the visual organ for the right side, the left for the left, and the optic nerve from each passes across entire to the opposite side of the brain—a complete analogy with the hand and ear in man. As we ascend the animal scale we find the eyes coming round more

FIG. 2.

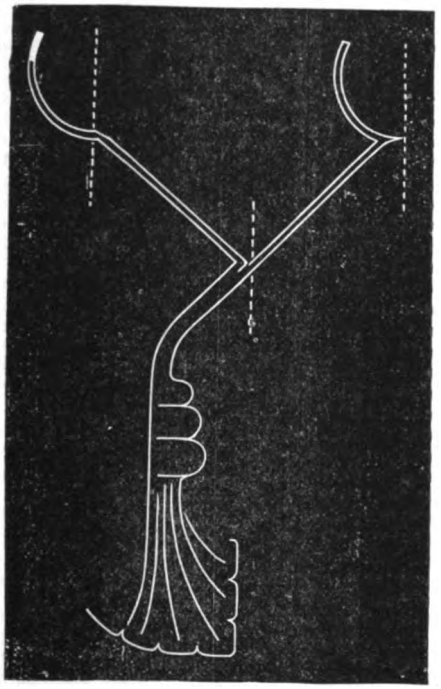

Diagram showing connexion of left half of each retina with lower (basal) and higher (cortical) visual centres.

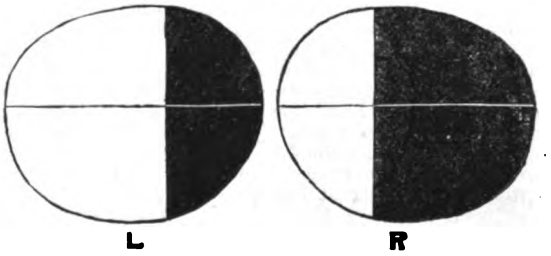
and more to the front, till in man they look nearly straight forwards. (Fig. 1, *b*.) Each eye sees both to the right and to the left, the left half of each retina receiving the pictures of objects standing to the right and *vice versa*. In man, therefore, the visual organ for the right side is not the right eye but the pair of half eyes which see in that direction, and this compound organ is connected like the right hand and ear with the left side of the brain. This is true not of the retina only, but of the eye muscles as well, as we shall shortly see. The connexion of the eyes with the brain is peculiar, then, if we regard the anatomical arrangement, but considered in relation to function it is similar to that of the other peripheral organs. Bearing this similarity in mind, let us look at the arrangement of the visual apparatus a little more in detail, first the sensory, then the motor portion.

The optic fibres from the left half of each retina join company at the chiasma, constitute the left optic tract, and form various connexions in the left half of the brain. These latter have been studied with infinite pains, but are not yet completely known. This much may be said with certainty: the optic fibres are connected, firstly, with certain lower centres in the basal ganglia (chiefly the external geniculate body, the pulvinar, and the anterior quadrigeminate body) and, secondly, with higher centres in the apex of the occipital lobe. (Fig. 2.) Clinical observations have amply proved that the chief centres for conscious visual perceptions lie in the occipital cortex and that a lesion situated in this region or at any point in the course of the optic fibres between it and the chiasma, causes blindness in the corresponding halves of the two retinæ—i.e., homonymous hemianopia (Fig. 3). I must

FIG. 3.



Fields of vision in complete right hemianopia indicating lesion behind commissure on left side.

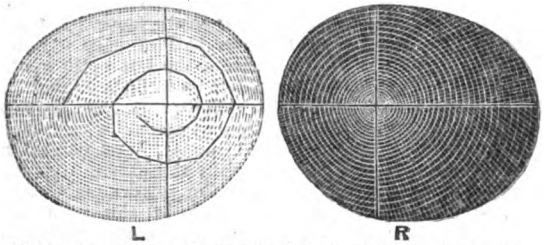
remind you, however, that according to some authorities certain lesions and disturbances of the brain cause not hemianopia but "crossed amblyopia"—i.e., not half-blindness of each retina but whole blindness of the opposite retina, and in order to explain this they assume that there is on each side of the brain another visual centre which is connected with the entire retina of the opposite eye. Let us glance at the evidence on which this doctrine of crossed amblyopia is based. It is of two kinds relating to lesions of the brain and to functional disturbances respectively. The clinical observations which have been cited to show that a brain lesion has caused blindness in the opposite eye with none in the near eye appear to be inconclusive. Nothing short of an accurate map of both visual fields can be accepted as valid evidence on this point, and this is not forthcoming. Patients suffering from hemianopia are often not aware that both eyes are affected; if they have blindness towards the right they tell us that the right eye is blind, and there can be little doubt that crossed amblyopia has sometimes been registered on a mere statement of this kind when hemianopia was really present. The experimental evidence is mainly that put forward by Professor Ferrier. He found that destruction of the angular gyrus in the monkey caused transient loss of vision in the opposite eye and convinced himself that this was not of hemianopic type. But in judging of this experiment we must remember that even in man the field of vision cannot be accurately mapped without help from the patient, and that in the monkey it can hardly be easier. Moreover, even in man hemianopia blinds a larger area in the opposite eye than in the near eye, for what we call the halves of the retina are not equal halves (Fig. 3), and in the monkey the inequality is presumably somewhat greater still. More important still, other experimenters have failed to produce discoverable blindness by destroying the angular gyrus unless the injury went deep enough to damage the fibres of the optic radiation which lie beneath it, and in that case the resulting blindness appeared to be of hemianopic type.

On the other hand, certain functional disturbances of the hysterical and reflex types are associated in some cases with a loss of vision which is not hemianopic. The field is not divided vertically, but is contracted concentrically all round.

Digitized by Google

The line which limits it is not sharply defined but uncertain and shifting, sometimes closing in while the patient is under examination, so that as we go round the field twice or more with the perimeter we get a spiral line which constantly approaches the centre. (Fig. 4 L.) This form of amblyopia is

FIG. 4.

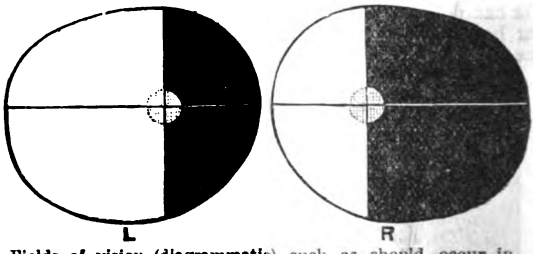


Fields of vision (diagrammatic) in so-called "crossed amblyopia." Variable concentric contraction, unequal in the two eyes. The spiral line (L) shows closing in during examination with the perimeter.

usually attributed to a disturbance in the cortical centres for vision. Now, when the two eyes are equally affected, as they usually are, this explanation involves no difficulty, for it is quite compatible with a semi-decussation of the optic fibres; but when, as happens in certain cases of hysterical hemianæsthesia, one eye is nearly blind while the other shows only a slight peripheral contraction of the field (Fig. 4), it involves the assumption that the whole of each retina is represented in the opposite hemisphere. Hence Charcot's hypothesis of a completed decussation, and the doctrine of crossed amblyopia. But is this amblyopia a direct result of cortical disturbance pure and simple? Is it not perhaps an indirect symptom, a retinal anæsthesia due to vaso-motor disturbance? Looking at the question from the ophthalmic standpoint there are, I think, some grounds for this view. The retina is constructed and nourished in such fashion that a general lowering of its nutrition necessarily leads to contraction of the field of vision. To demonstrate this we have only to press the eyeball moderately with the finger so as to retard, without arresting, the internal circulation; we get a lowered vision and a contracted field which much resemble hysterical amblyopia. Clinically we sometimes see cases in which similar symptoms are clearly due to a reflex disturbance of the circulation in the eye; the blindness usually passes off, leaving the vision normal, but occasionally, after several transient attacks, it remains permanent and we then find the signs of arrested circulation in the retinal artery. I have published a series of such cases; allow me to refer to one. A young married woman suffered many attacks of transient blindness, sometimes with fainting, always with a tendency to faint. They were brought on sometimes by hurry and agitation, as in catching a train, but most distinctly by the use of a vaginal syringe. There was, she thought, a tender spot which the syringe sometimes touched, and whenever this happened she felt faint and the sight failed. From one of these attacks of transient blindness the left eye did not recover; it remained permanently dark except just at the macula, and presented the usual signs of arrested circulation in the retinal artery. Here was certainly a reflex disturbance of the intra-ocular circulation, combined probably with a condition of depraved blood. The other eye remained amblyopic and sometimes went dark for an hour together; it was obviously in peril. The patient was placed under the care of Dr. Malins, who found double pyo-salpinx and removed the ovaries and tubes. The remaining eye then quickly and permanently recovered. This was in 1883, and I heard not many months ago that the good result is still maintained.[1] Taking all these facts into consideration, it seems possible that the so-called crossed amblyopia may prove to be a reflex retinal phenomenon rather than a sign of disturbance in the cerebral centres for vision.

I will venture to carry this heresy a step further. In hemianopia the line which divides the blind from the seeing area sometimes passes to one side of the fixation point instead of through it, so that the patient, to his great advantage, retains his sight in the whole of the macular region instead of in one-half only. To explain this imperfect bisection it has been assumed that the whole of the macula is represented in each hemisphere, so that its activity is maintained by either in spite of a lesion in the other. This is the doctrine of crossed amblyopia in a different and less complete form; but surely if the whole of the macular region in each eye, as distinguished from the rest of the retina, is represented in each hemisphere, it ought in hemianopia to be spared in a symmetrical form and it ought to be lowered in sensibility throughout by a lesion of either hemisphere (Fig. 5); but

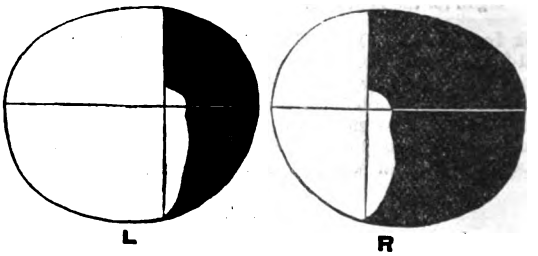
FIG. 5.



Fields of vision (diagrammatic) such as should occur in hemianopia if the hypothesis of double representation of the macula were true.

such fields are not found. The dividing line, when it spares the macula, usually takes an irregular direction and spares a portion of the periphery as well (Fig. 6.) An incomplete hemianopia like this would seem rather to indicate that the lesion has fortunately spared some portion of the visual fibres or cortex on its own side of the brain, and it is by no

FIG. 6.



Fields of vision such as actually occur, presumably when certain fibres on the same side as the lesion are spared.

means unlikely that the macular fibres have some advantage in this respect—that they escape when other less important fibres suffer. They are very numerous in proportion to the area which they supply, they are functionally the most active, and they are the best protected by their central position in the tracts as well as in the optic nerves.

At present, then, we may, I think, regard the doctrine of crossed amblyopia as unproved, and we may hope that those bewildering diagrams in the text-books which show the fibres from one retina, first making a semi-decussation at the chiasma and then changing their minds and re-uniting in a common centre in the opposite hemisphere, will turn out to superfluous.

The motor mechanism of the eyes consists essentially of three parts: the muscles, the nerves which convey impulses to them, and the brain centres which issue the impulses. Every movement, except inward and outward movements in the horizontal plane, requires the combined action of two or more muscles for each eye, and every impulse to one eye is accompanied by a simultaneous impulse to the other; it is evident, therefore, that the guidance of the two eyes from one point to another in the field of vision is a highly complex act. The simple sideways turning of the eyes has been likened to the driving of a pair of horses, and if we imagine the coachman to be supplied with certain extra reins so coupled together that he can at pleasure turn his horses' heads not merely to right or left, but upwards, downwards, towards each other, or away from each other, and if we imagine him to have hands enough and skill enough to make every possible combination of these movements with hairbreadth precision, we can picture the way in which the brain centres control the eyes through the three pairs of nerves which actuate the muscles. As regards movements in the horizontal plane their action may be illustrated by this model (Fig. 7). Please observe that it does not pretend to represent anatomical structure—that is an extremely intricate matter; it is

[1] Ophthalmic Review, 1884, pp. 2 and 144.

Digitized by Google

merely a working diagram to demonstrate the principle of bilateral coördination. The centre for convergence (C) turns both eyes towards the median line; that for divergence (D) away from the median line; the conjugate centre on the left side (R) turns both eyes to the right, that on the right (L) both eyes to the left. For different purposes the same muscles are actuated by different centres, and are differently associated one with another. In every case the impulse is bilateral—i.e., is issued to the two eyes simultaneously. Moreover, the impulses here illustrated are associated more or less closely with others not shown in the model; convergence is associated with accommodation and contraction of the pupils, and to some extent with movement of both eyes downwards; divergence with upward movements of the eyes and lids; conjugate lateral movements to some extent with lateral rotation of the head. That these coördinated impulses

FIG. 7.

spring from distinct foci or centres in the brain-substance is no longer open to question, for a lesion at a certain spot will abolish one form of bilateral movement and leave another intact, so that a given muscle, required in both, is at one moment paralysed, at another active, according to the nature of the attempted movement. Moreover, the experimental physiologist can call forth one or other of these compound movements by placing his electrode on one or other spot in the brain.

As regards the exact positions of the various centres I will not attempt to speak. I will only remind you that the motor centres like the visual centres are of two or more grades, the lower being in the neighbourhood of the corpora quadrigemina, and chiefly in the grey matter which forms the floor of the third and fourth ventricles, the higher in the cortex of the frontal lobe. The lower appear chiefly to supply the motive force, the higher to exercise conscious control.[2] The sensory and the motor portions of the visual apparatus interact upon each other. No mechanism however delicate could turn the eyes swiftly and surely from one point to another without precise information as to the position of the point at which it is to aim. Here, as elsewhere, throughout the body, sensation guides movement through channels connecting the sensory with the motor centres. Experiments have proved the existence of such channels. The electrode applied to a certain point in the visual area of the cortex induces eye-movements in a certain direction: it excites, presumably, a visual impression, which, when conveyed to the motor centres, causes them to turn the eyes toward the point in space from which that impression would normally be received. In this way the actual position in which the retinal picture is reproduced in the occipital cortex has been to some extent determined.

Such, very roughly sketched, is the mechanism by means of which we enjoy the faculty of binocular vision. Do we bring it with us into the world ready made, or do we make it each one for himself? The question has been much debated and has an intimate bearing on the causation of strabismus. Unquestionably, the infant is born with the visual machinery, including its chief coördinations ready made, but only in the rough; if he is to enjoy the use of it he must complete it and make the fine adjustments for himself, and he must do this while the structure is still plastic and in the act of growth. Any interference with the education of the eyes in very early life is apt to leave a permanent disability. Let me put before you a few well-observed facts as to the development of vision in infancy. The newborn child[3] is sensitive to light at once, or at latest within a few hours; the pupils respond to light, and both respond when it falls on one eye only; the reflex closure of the lids under the sudden afflux of light is present also. The conscious perception of objects and the response thereto, e.g., the closure of the lids when an object suddenly approaches the eye, is absent during the first few weeks. The first movements of the eyes, like those of the limbs, are purposeless; they occur sleeping as well as waking and have no relation to external objects. They are often clearly of the bilateral associated kind: both eyes turn to one side, or both turn inwards, assuming a position of excessive convergence which is indistinguishable from squint. They are often asymmetrical, one eye making larger excursions than the other, or remaining at rest while the other moves. Observe, however, that this asymmetry does not prove absence or abeyance of bilateral coördination. Such movements may be, and frequently are, produced in ourselves by the combined action of two bilateral impulses. For example, I am now looking with both eyes at a distant point. I place a finger in line between this point and the right eye and then look at it with both. What happens? The right eye remains directed as before, the left turns inwards, the movement is asymmetrical, but it is due to the simultaneous action of the centre for convergence, and the conjugate centre for movement towards the right. Such movements in the infant show not want of coördinating mechanism but want of purpose; the lower centres are acting uncontrolled by conscious perception in the higher. The movements in which absolute coördination is certainly wanting are just those in which it remains incomplete throughout life—viz., the vertical movements of the eyes and eyelids. We can most of us even in adult life contrive on occasion to wink with one eye only, and many can turn one eye upwards or downwards a little more than the other in order to neutralise the effect of a weak prism. Soon the infant begins to perceive the pictures on his retina, and may as early as the fourth week begin to follow the movement of a bright object before his face. Purposive movements in search of objects lying to one side begin a little later. Horizontal movements, which are stronger throughout life than the vertical, are learned first: a child of fourteen weeks has been seen to follow the oscillations of a clock pendulum, but not till near the end of his first year does he follow the objects which he drops from his hand to the floor. Voluntary convergence, as in watching the approach of an object towards the face, appears about the third month accompanied by first experiments in the art of accommodating. A knowledge of distance is learned gradually after countless experiments in grasping at things which are out of reach. Recognition of objects also is gradually learned; of faces about the sixth month; of bottles, cups, spoons, and so forth about the ninth; by the twelfth month the child watches all that goes on in his neighbourhood. These observations show that we owe the faculty of binocular vision, as we owe some still higher faculties, partly to inheritance and partly to our own diligent use of what we inherit.

For what purpose are the peripheral organs of vision duplicated in the remarkable manner we have been considering? Why not one eye for the right side and one for the left, as in the fish? or, granting that an intelligent being does well to look forwards rather than sideways, why not one

[2] See chapter on Automatism and Control, in Lloyd Morgan's Introduction to Comparative Psychology. 1894.

Digitized by Google

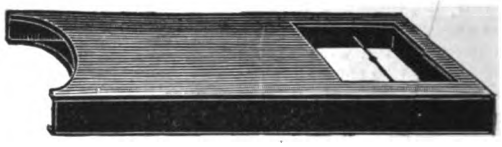
large eye in the middle of the forehead like the Cyclops? The purpose is that we may look at every object from two points of view and thereby comprehend it better; in other words, that the brain shall receive two different pictures of the object and yet shall receive them in the same place, so that it may easily blend and yet compare them—fuse and yet differentiate them. This process is learned in early infancy, and when learned is performed almost unconsciously; we hardly know that the mental picture is a blend of two retinal pictures, or that the latter differ from each other. The fusion of the two pictures is promoted by the special sensitiveness of the macula. The infant soon learns that he sees an object best when it is pictured simultaneously on the two maculæ and he directs his eyes accordingly, bringing an identical point in each picture precisely to the central point of each macula. So precise does this fixation become that a good observer has little difficulty in consciously directing his eyes to either of two adjacent points, even where these are so small and so close together as to be only just distinguishable. The fusion of the two pictures as regards their outlying parts is a less simple matter. If they were exactly similar, like two prints from one negative, they would, of course, coincide throughout, but they are not so; they are two photographs taken from different points of view, and it is precisely their difference which gives the compound mental picture its special value. This is well known to those who are familiar with the use of the stereoscope. Here is a very simple illustration. I look at this pencil while holding it a little to the right of the middle line and pointing towards me. The left eye sees it more sideways, the right more endways, than its fellow. The two retinal pictures may therefore be represented by two lines of unequal length (Fig. 8). How can two pictures so

FIG. 8.

Dissimilar retinal pictures of a rod held before the eyes to the right of the middle line and pointing forwards.

different be fused, and what sort of mental picture can they produce? Place them in the stereoscope so that the right eye receives the one, the left eye the other, and the question is answered. For a moment both are seen in confusion; then suddenly they spring together, as it were, and the confusion ceases; experience tells us that their discrepancy could only be produced by an object placed as the pencil was placed, and we see, not a long line or a short line on the flat paper, but a single line in perspective. In forming our judgment as to the position of the pencil, the motor apparatus of the eyes assists the sensory; our eyes travel from one end to the other, and in so doing the left makes a greater excursion than the right; this difference in the movements of the two eyes confirms the knowledge derived from the difference between the two retinal pictures.[4] In blending the constantly varying pictures which the two eyes receive we habitually disregard those portions whose discrepancy would otherwise confuse us. For example, I hold a finger at twelve inches from my face and another at half that distance; now, while I look at the further one, the nearer, if noticed carefully, is seen double, and *vice versâ*. Physiological double images of this kind are constantly before our eyes, they are the discrepant portions of the two retinal pictures; usually they are unnoticed, but they are not unseen and they are not unused. They largely subserve our perceptions of distance and perspective. Here is a beautiful illustration of the value of unrecognised double images. The box (Fig. 9) represents Hering's drop test in a slightly altered shape. Across it, near the far end, is stretched a white thread with a knot at its middle point. I look into the box with both eyes open and fix my attention on the knot. My assistant drops a white bean through the box, either in front of, or behind, the thread. I can say with certainty every time whether it passes in front or behind. Now, if I shut one eye I see the bean pass as before, but I have no idea whether it passes in front or behind. When both eyes are used, the bean, being nearer or further away than the point at which I am looking, is seen double; if it is nearer the image belonging to the right eye stands to the left, and *vice versâ*—in other words, the images are crossed; if it is further they are not crossed. Now please observe that in this experiment one is not conscious of seeing double, yet the two images are not only received by the percipient

FIG. 9.

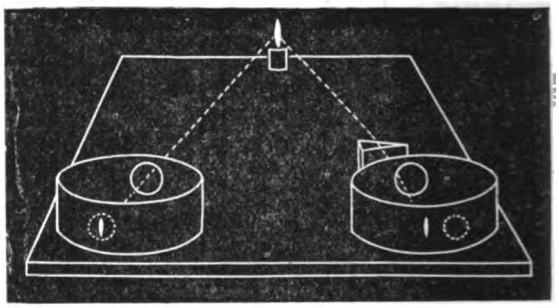


A convenient form of Hering's drop test for the presence of binocular vision.

centres but are differentiated the right from the left, and on the information thus obtained one judges correctly as to the position of the bean during its momentary transit through the box. This is a very delicate test for the presence or absence of true binocular vision.

And now, lest it should be supposed that these phenomena of single and double vision, though interesting as questions of physiological optics, have no bearing on practical work, I will conclude with an application and an actual case. The model (Fig. 10) represents the two eyes and the object at

FIG. 10.



Model showing displacement of retinal image by means of a prism.

which they look—a lighted candle. Both eyes being properly directed the candle is pictured on the macula in each. If either eye were to deviate the picture in it would be displaced from the macula and the patient would see double. This he habitually avoids. Now we can displace the image and produce double vision artificially by placing a prism before one eye. What happens then? The patient instinctively moves his eye in order to bring the macula to the image and get rid of the double vision. He does this involuntarily or even against his will; he cannot help doing it. This is a useful test for sham blindness. If the eye moves behind the prism and again when the prism is removed it is no use his telling us that it is blind. A few months ago a prisoner awaiting trial for burglary with violence awoke one morning blind in both eyes—so he said. The prison surgeon had no doubt that he was shamming, but wanted positive evidence one way or the other, and we examined him together. The man declared himself to be quite dark in both eyes and acted the part of a blind man fairly well, overdoing it a little. The pupils were already under atropine and could therefore give no evidence as to the light reflex. A lighted candle was placed before him in a dark room. He was not required to "look" at the candle, being nominally blind, but the candle was placed about where he appeared to be looking. A prism was then placed before one eye, its base inwards; instantly the eye moved outwards. The prism was removed and the eye moved inwards. The man was told that his blindness would certainly disappear as quickly as it came, and he probably understood that the fraud would get him into more trouble if persevered in. His sight was soon restored. Now, if this man could have carried his blindness into the dock a merciful judge and jury would not improbably have felt that a higher tribunal had already visited him with a heavy punishment, or at least that he was

incapacitated for further crime, and have dealt leniently with him. As a matter of fact, he was a particularly daring and dangerous criminal, and had attempted, during a former imprisonment, the life of the prison surgeon. He received a long sentence. This case, of course, was somewhat exceptional, but the question whether the two retinal pictures are properly blended in the brain arises not only in connexion with feigned blindness but in many common conditions. In my next lecture I shall have to point out its importance in relation to the causes of strabismus.

ABSTRACT OF

A Clinical Lecture

ON

TWO UNUSUAL CASES OF HERNIA.

Delivered at King's College Hospital on Jan. 13th, 1896,

BY WILLIAM ROSE, M.B., B.S. LOND., F.R.C.S. ENG.,

SENIOR SURGEON TO KING'S COLLEGE HOSPITAL AND PROFESSOR OF CLINICAL SURGERY IN KING'S COLLEGE, LONDON.

GENTLEMEN,—There are at present in the hospital in my wards two unusual cases of hernia which are worthy of special mention from a clinical standpoint in that they both illustrate the fact that nature is occasionally able to effect a cure without the intervention of surgery. They are exceptional cases and not typical either in their clinical history or in the line of treatment adopted. Although the results have been satisfactory, yet I shall conclusively prove to you that these patients have not attained their present favourable conditions without considerable risk to their lives. In the former of these an irreducible femoral epiplocele became strangulated, and when seen and admitted to hospital gangrene of the hernial contents and adjacent skin was present with marked toxæmic symptoms, whilst in the latter a more chronic process of inflammation had been going on for years between the sac wall and an irreducible portion of omentum surrounding a prolapsed and elongated vermiform appendix, leading finally to the shutting off of these structures from the general peritoneal cavity. In one, then, the process has been acute and the danger great, and in the other chronic, but the risk, though less, has still been considerable.

CASE 1.—A woman aged fifty years was admitted to the Wigram Ward of King's College Hospital on Jan. 3rd, 1896. Three weeks before admission she first noticed a lump in the groin on the right side as the result of a severe attack of vomiting brought on by excessive drinking. She continued to work, however, till two days before admission, when the swelling became larger, much more painful, and the skin over it was red and tender. On the following day it burst, and gave exit to a quantity of foul-smelling fluid, which the patient described as like stinking onions. On admission she presented symptoms of toxæmia, an anxious countenance, a dry and furred tongue, and a small, rather hard pulse. The temperature was normal. There was nausea, but no vomiting, and, indeed, she stated that she had not vomited since the swelling burst. Absolute constipation had been present for some days. In the right groin a little above the saphenous opening there was a large black slough protruding through an oval aperture in the skin about two inches in diameter. It had the characteristic appearance of dead omental tissue, and from its interstices a quantity of offensive sero-pus could be squeezed out. There was no appearance of fæcal escape and no general abdominal tension or tenderness. The soft parts in the neighbourhood of the wound were red and œdematous. From the absence of any of the graver symptoms a diagnosis of strangulated omental hernia was made. The wound was dusted over with iodoform and charcoal poultices applied. Fluid diet in small quantities was ordered, and the bowels were not opened until the third day, and then by an enema. The patient made steady progress, the sloughs separating, and the wound gradually healing.

The chief points of importance to be noted in this case are: (*a*) the modified symptoms which are exhibited when omentum alone is strangulated and the bowel not involved; (*b*) the localisation of the destructive and inflammatory process to the hernial protrusion and parts immediately around; (*c*) the source and nature of the septic process in the omentum; and (*d*) the treatment of the case.

Unquestionably, the occurrence of a pure strangulated epiplocele is rare, and your text-books give but little information on the subject, the symptoms ascribed to this condition being mainly those which arise when the gut is also involved. Vomiting commencing with the contents of the stomach and gradually becoming fæcal, abdominal distension, pain radiating from the umbilicus, a quick and so-called wiry pulse, an anxious countenance, a dorsal decubitus with the thighs and legs flexed are the cardinal features of such a case. Constipation may or may not exist. Such conditions are considerably modified, however, and some of them absent when omentum alone is involved. The vomiting may be slight in amount and is seldom persistent, rarely fæcal. Peristalsis, although somewhat hampered, is not arrested, consequently constipation need not be present. In short, all the symptoms are of a milder type, and hence it frequently happens that the existence of strangulated omentum is not recognised for some days after its incidence, particularly in women where there is a natural disinclination to mention anything that would necessitate an examination of the groins. It is, therefore, very important to put the question very decidedly as to the existence of any unusual or recently formed swelling in this region or at the umbilicus. Again, it must not be forgotten that an irreducible omental hernia may at any moment become complicated by the intrusion into the sac of a knuckle of intestine, which not only becomes itself strangled, but also determines the occurrence of similar changes in the omentum, giving rise then to all the characteristic signs of acute obstruction. Moreover, it not infrequently happens that a similar train of symptoms may be induced when a large amount of omentum becomes protruded and adherent or strangled, causing at the same time excessive traction and angular kinking of the large bowel, probably at the most fixed portion—viz., the splenic flexure.

The local signs of a strangled epiplocele differ in character from those which obtain when bowel is involved. In the latter a rounded, tense, tender swelling can usually be felt, devoid of impulse and irreducible. On the other hand, the omental swelling is soft and doughy, but painful and irreducible. The amount of fluid in the sac varies considerably, being usually scanty. Such a swelling in the femoral region has frequently been mistaken for an inflamed lymphatic gland or an accumulation of fat, but the fixed base and the inability to define the margins of the saphenous opening should prevent a mistake in diagnosis, and taken with the other symptoms should suffice to induce the surgeon to make an exploratory incision. When the patient whose case we are now reviewing first came to the hospital these earlier and more typical phenomena had been superseded by those of local inflammation and gangrene, the result of bacterial infection. It was abundantly evident from an examination of the surrounding parts how virulent was the local action which was here at work, and yet it is instructive to note how rapidly and efficiently nature had succeeded in sealing off the general peritoneal cavity by a plastic effusion, which was of sufficient vitality to become rapidly vascularised and so withstand the extension of the destructive process.

As to the source of this infection there is room for speculation. It is certain that the putrefactive changes commenced from within and spread outwards; but the mere fact of omentum being strangled does not in itself determine a putrefactive change, as is often exemplified in the operation for the radical cure of hernia, where we are in the habit of returning large masses of ligatured omentum without risk. One is, therefore, driven to the conclusion that an autoinfection of some kind or other must have occurred in this case, probably due to the migration of bacilli from the neighbouring coils of gut, either kinked or restricted in movement by the traction of the incarcerated omentum.

In deciding as to the immediate treatment to be adopted one naturally asked the question whether or not any strangulation of the intestine was present. The local and general conditions of the woman gave a decided negative to this query. Granted that no portion of gut was implicated, it

Digitized by Google

was obviously undesirable to interfere with the process of nature beyond assisting in the removal of the necrotic tissue, for any incision made with a view of relieving the constriction would necessarily open up the barrier existing between the healthy and infected regions, thereby exposing the patient to the risk of general peritonitis, whereas, if the necrotic tissue was allowed to separate or was scraped away, every care being taken to disinfect and purify the locality, one might reasonably anticipate a favourable issue, even if it involved the fixation of the omental stump to the abdominal parietes. If after the wound has healed the patient should complain of pain and threatening obstruction from restricted peristalsis, an operation for the relief of the deep adhesions can be resorted to under more favourable auspices.

CASE 2.—A woman aged sixty-two years was admitted to the Wigram Ward on Jan. 2nd, 1896, suffering from a large irreducible femoral hernia on the right side extending upwards and outwards over Poupart's ligament. The origin of this protrusion dated back to a confinement thirty-eight years ago. She has occasionally worn a truss, but at variable intervals has had severe attacks of pain localised to the hernial sac and evidently due to a limited peritonitis. The tumour has increased in size considerably during the last seven or eight months. On admission it was hard and irreducible, but not tender to the touch. She has also suffered much from general dyspepsia and attacks of vomiting. On operation I found adherent to the sac a large mass of omental tissue which had undergone a sclerotic change as the result of the repeated attacks of inflammation; it was completely shut off from the general peritoneal cavity. Running through the centre was a tubular body, which proved on dissection to be a long vermiform appendix. This and the dense mass of omentum were removed on a level with the femoral opening and the wound healed in a few days.

In comparing this case with the other I would again remind you of what I stated at the beginning of the lecture—viz., that nature had here effected a cure before I interfered, and that the operation merely consisted in removing a superfluous mass of changed omentum and the appendix, which had long since been isolated from the abdominal cavity. Indeed, so firm was the plugging of the femoral canal that it was not necessary to disturb it in any way. At the same time it must be evident to you all that this woman was for a long time in very considerable danger with a prolapsed vermiform appendix in addition to the omental protrusion. At any moment a coil of gut might have passed into the sac and led to strangulation, or a similar condition of acute obstruction might have been induced by kinking of the gut from dragging or twisting of the omental connexions. Again, the prolapsed appendix might have become acutely inflamed, although this condition is extremely rare.

The presence of the vermiform appendix in a hernial sac is not a common occurrence, although not a few cases have been recorded. Personally, although I have operated on hundreds of cases of hernia I have not met with this condition more than half a dozen times. Some years ago I was called in by Mr. Alfred J. Bell of St. John's Wood to operate on an old lady over eighty years of age who was suffering from acute strangulated femoral hernia, and I there found the appendix in the sac in addition to a coil of intestine. The removal of the former and the usual operation of radical cure were followed by an uneventful recovery. No doubt in this latter case the appendix had been the first tenant of the hernial sac and had paved the way for a prolapse of the bowel, which had subsequently become strangulated. In the former case no coil of bowel happened to become involved.

In conclusion, I must repeat that these two cases are of a very exceptional character and must not be looked upon as in any way typical of the ordinary run of cases of incarcerated or strangulated hernia with which you will have to deal in your practice.

WIGAN MEDICAL SOCIETY.—The ordinary meeting of this society was held on June 4th, Mr. C. R. Graham, President, being in the chair.—Dr. Judson S. Bury, assistant physician to the Manchester Royal Infirmary, read a paper on the Diagnosis of Functional from Organic Disease of the Nervous System.—A discussion followed, in which Mr. Hugh E. Jones, Mr. Cowan, Dr. R. P. White, Mr. Benson, and the President took part.—A cordial vote of thanks was passed to Dr. Bury for his able paper.—Dr. Bury replied.

A CASE OF CONFLUENT SMALL-POX IN A LASCAR.

BY ALEXANDER MACPHAIL, M.B., C.M. GLASG.,
DEMONSTRATOR OF ANATOMY, GLASGOW UNIVERSITY.

THE following notes, chart, and drawings form the record of a case of confluent small-pox which ran its course to a fatal issue on the high seas between the ports of Colombo and Suez, and are mainly interesting from the fact that a complete record of such a case is not often obtainable, the patient having been one of a Lascar crew. A secondary interest attaches to the record in that I was at the time surgeon on board the ss. *Clan Mackenzie*, and had not previously seen a case of small-pox, so that the diagnosis had to be made and the case conducted without such aid as anyone familiar with the disease might derive from early signs; and it was only determined after a careful study of the notes taken from day to day, which are given below, together with some remarks on the chief points of interest.

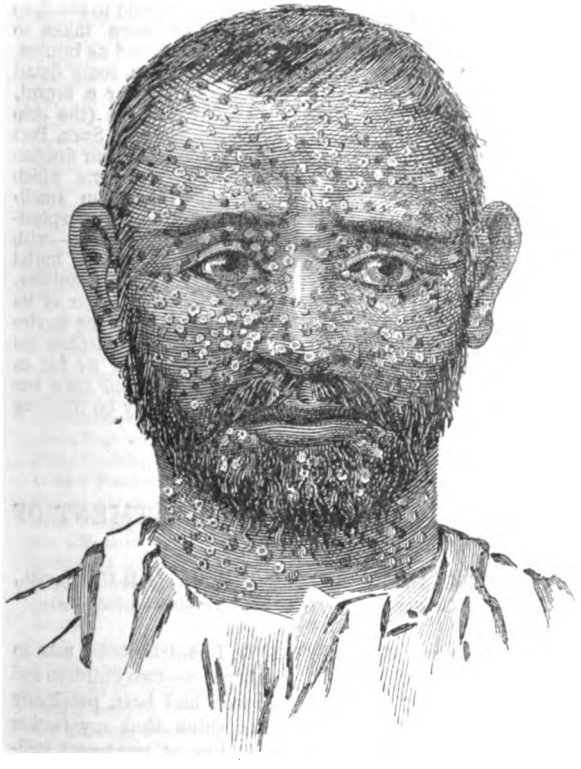
On Sept. 18th, 1894, a man aged thirty-five years first complained of headache and pains in the back and limbs. The skin was hot and dry. The temperature was scarcely febrile in the morning, but reached 101°F. by the evening. He was given quinine in ten-grain doses. On the 19th the temperature was steadily rising; there was profuse sweating. The pains were general and more severe. The patient was also suffering from depression and sleeplessness. On the 20th the fever was more marked and the pain less. There was severe vomiting shortly after a dose of quinine in the morning, and phenacetin was substituted. The vomiting reappeared several times in the course of a few hours. On the 21st, although there were symptoms of greater ease, the morning temperature rose still higher, with a fall of 2° after exhibition of phenacetin again at midday, when the patient drew attention to a few spots on his forehead, like ordinary pimples, but hard, while a few similar spots were felt on the right cheek. These were not regarded as of much importance, and no rash could be seen; but on the evidence of continued pyrexia and inexplicable fits of vomiting the patient was isolated, disinfectant measures were adopted, and the temperature was taken more frequently. On the 22nd distinct papules appeared all over the body, with very slight signs of congestion, but in almost all cases giving a "shotty" feeling to the touch. The temperature reached a crisis at 104·4° in the afternoon and fell again towards evening. Isolation and disinfectant measures were more strictly enforced on the first suspicion of small-pox. On the 23rd there was a decided lysis of the temperature almost to normal, with slight exacerbation in the afternoon. The symptoms were much relieved, and the pulse, though not notably accelerated previously, became almost normal in number and fulness of beat. The eruption was still nondescript, some of the spots showing an advance towards breaking and scabbing and others to surface blackening. On the 24th the temperature was still oscillating at the lowest febrile degree. The individual spots were more prominent, broader, and flat, and dull chocolate in colour. (See Fig. 1.) Sleeplessness was also present for which bromide of potassium was exhibited. On the 25th the morning temperature was normal, but febrile again at night. Delirium was very marked during the night, the eruption assuming the above-mentioned characters all over. Acupuncture of the flat elevations revealed serous fluid contents. There was slight confluence on the forehead and cheeks, the lips and tongue were swollen and marked by distinct papules, and one or two clear vesicles were seen on the sides of the tongue. On the 26th the temperature was oscillating. There were a few distinct pustules on the face and in the fold of the groin. The whole face was much swollen and the pulse became rapid and thin. On the 27th the temperature was increasingly febrile and the pulse was 112, weak, and dicrotic. Noisy and incessant delirium was present, the spots all over the body becoming pustular (Fig. 2). The eyelids were matted with purulent matter and there was a discharge from the nose. The patient showed great thirst. The urine was very concentrated. Zinc powder and perchloride of mercury lotion were applied externally, while digitalis and stimulant were given internally. On the 28th all the symptoms were less severe in the morning and throughout the day; the pulse, although weak, was less

Digitized by Google

rapid; the temperature was 99·8° in the morning, rising again during the afternoon; the delirium was gone. Death took place unexpectedly at night, the patient having spoken cheerily to his comrades through the partitions a few minutes previously.

Remarks.—The duration of the period of incubation can be very definitely fixed, as the patient had been, on his own information, in direct contact with a case of small-pox on Sept. 5th and 6th, his own initial symptoms appearing on the morning of Sept. 18th. During this time he had never complained of any indisposition, although the captain had remarked on a drowsiness and inactivity quite unusual to the patient. The first complaint was made in company with three other native servants who had got a wetting the previous night and had thereafter gone to sleep for a few hours on the saloon floor in order to be at hand when the ship arrived at Colombo. They all complained of symptoms which at once suggested the early stages of an attack of ague—viz., headache, pains in the back and lower limbs, and hot, dry skin, the temperature, though above normal, in no case being febrile as yet. Malarial fever, or simply

FIG. 1.



Fifth day of eruption: vesicular stage.

"fever," as it is called by them, is always smouldering in a Lascar crew, and as similar causes had accounted for several well-marked cases in the previous voyage, the diagnosis of malarial fever was considered secure and the routine treatment—by quinine sulphate in ten-grain doses every few hours—was adopted. The relief following the exhibition of quinine in all the cases, with this single exception, seemed to justify this diagnosis, and it was fully anticipated that this case too would soon subside under its influence. On the contrary, the temperature curve was still rising (although unattended by any new symptom) on the second day, and continued so till the morning of the third day, when severe vomiting and retching set in. This was at first attributed to the usual dose of quinine, but in spite of phenacetin having been substituted it came on several times during the day and was seemingly independent of any stomach irritation, there being only a slight emesis of bile-coloured fluid, pointing rather to a constitutional cause, associated no doubt with the invasion of the disease. The temperature chart gradually evolved a curve resembling that typical of small-pox, a somewhat abrupt rise from normal to 104·4°, which crisis was reached on the fifth day of illness and one day after the first appearance of the exanthem. This was interrupted on two occasions by phenacetin, which produced a transitory fall. Coincident with the outbreak of the papules all over the body a distinct lysis set in, the temperature becoming almost subfebrile in the course of twenty-four hours, and, oscillating there for two days, on the morning of the third day reached normal. The secondary curve, which began to develop on the same day, although intermittent, showed a steady rise, reflecting the process of pustulation and consequent blood-poisoning. The pulse in the earlier stages presented no feature out of proportion to the degree of fever present, and only when the secondary fever set in was there any notable feature; then its rate increased as its strength diminished, its character becoming distinctly thready. These qualities were markedly changed by the administration of two doses of fifteen minims each of tincture of digitalis and some stimulant. From an early date the exanthem was regarded as significant of a specific fever, but, in the absence of previous experience of small-pox, was not for some time confidently held to indicate the presence of this disease. In the early stage the spots were distinctly "shotty," but might have passed

FIG. 2.

Seventh day of eruption: pustular stage.

except for the absence of a distinct "core" as ordinary pimples. The rapidly increasing area over which they began to appear and their transition into flat, hard elevations, mostly without any manifest congestion, led to a cross-examination of the patient as to his ever having seen a similar eruption. He said he had, and was sure that it was a certain disease common among natives of India, to which he gave the name "hoom," but which I have been unable to identify farther than that it is sometimes used to describe chicken-pox and is more loosely applied to many skin affections. When asked if he was familiar with small-pox the important fact was elicited that he had been staying for a few days, when the ship was lying at Calcutta, with an uncle stricken with small-pox there, and, in entire ignorance of any theory of infection, had been in constant communication with him as with any ordinary invalid. Though important this was not regarded as conclusive proof, for until it had assumed the characters shown in Fig. 1 the eruption did not seem to conform to the usual description of a small-pox vesicle; indeed, it did not suggest the presence of fluid

Digitized by Google

at all, but presented a slightly elevated, usually oblong surface, quite firm to the touch and of a dull chocolate colour. Other characters common to the small-pox exanthem were, however, present—viz., distinct depression as if from drawing together of the centre in some cases, in others a softening of the surface with scabbing, without any evidence of the usual cycle of vesiculation and pustulation. Distinct vesiculation such as is suggested, to quote any one of the recognised authorities, by the description "hemispherical in form and opaline in appearance"[1] was not manifestly present, and, as many other indications pointed to the eruption being that of small-pox, proof of vesiculation was sought for by puncture of one of these flat elevations; the result was the escape of a small amount of serous fluid removing all doubt of the condition. Previous experience might have led to the same conclusion at an earlier stage, but as the decision of the true nature of the case was one of immense importance to the ship's company it was delayed by the outlook for such a condition as the common description of vesiculation had suggested. Subsequently confluence of these areas and the appearance of pustulation took their usual course, producing the appearance seen in Fig. 2, the only additional fact worthy of remark being the presence of black scabs among the pustules indicating unusually speedy maturation here and there. The prognosis was not at first grave, the only disturbing factors in the early stages being the great tropical heat both by day and night and the early appearance of delirium. The extensive confluence in the later stages indicated a serious outlook. Curiously, what appeared to be the turning-point towards recovery must have been a final struggle on the part of nature, for on the day preceding his death the patient had for the first time expressed himself as "getting better," and his general condition had, moreover, apparently improved.

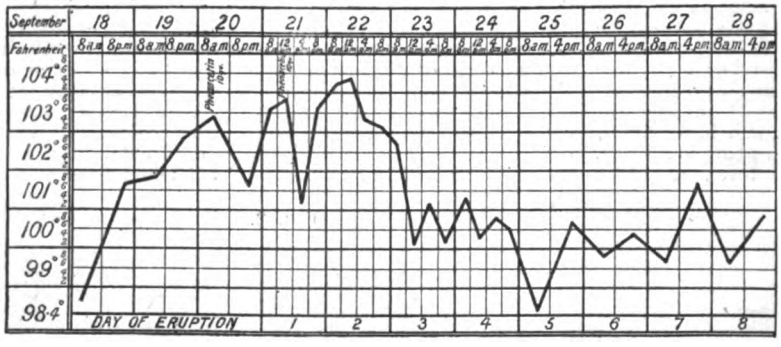


Chart showing rise until Sept. 22nd, when the temperature was over 104° and there were spots all over the body. Coincidently with the appearance of the rash the temperature fell.

With regard to treatment, little could be done medicinally. Quinine evidently had little or no effect in controlling the initial fever, although phenacetin in equal doses (ten grains) took effect upon two occasions. Bathing the eyes with a weak solution of perchloride of mercury gave much relief, as also did the application to the face of boric and zinc powder on a mask of boracic lint. Milk diet was adopted on the first evidence of continued fever; condensed milk only being available, this was given with fine-boiled rice three times daily. Alcoholic stimulant, for which there seemed no indication till the onset of the secondary fever, was at first refused on religious grounds (its use involving loss of caste), but was insisted on later when strength was evidently failing with good, although temporary, result. Isolation was at first no easy matter owing to the Lascars, having no idea of contagion, trying to communicate with the patient; the cabin had to be barricaded so that entrance could only be obtained in sight of the watch on the bridge; the delirium of the patient added another danger, as on one occasion he rushed out on deck and was got back with difficulty. On my part, too, there was great need for caution, as the case had to be taken full charge of in addition to my ordinary duties. To allow of this special clothing was set apart for my visits; my cabin was occasionally fumigated, and a hot bath, impregnated with Condy's fluid, was taken after every visit. Disinfection in the cabin set apart for the patient was effected by means of a moist sheet sprinkled with carbolic solution hung over the doorway. All food, &c., was passed to me through the barricades and the dishes washed with carbolic solution after use. After the death of the patient his cabin was washed down with the steam hose and afterwards scrubbed with carbolic acid, while both it and the forecastle adjoining were well fumigated. It was with difficulty that the Lascars could be argued into leaving to me the preparation of the body for burial, and, while conceding this, they insisted on holding a burial service on deck. Every precaution was taken by the captain, who stopped the ship and ran her broadside to the wind. Three of the Lascars who bore small-pox marks were chosen to remove the body from the cabin (where it had previously been wrapped in well-carbolised sheets and canvas) to the deck, where they deposited it on one side; the whole of the Lascar crew assembled on the other at a distance of some four yards while the service, lasting a quarter of an hour, was conducted. After the body was consigned to the deep additional precautions were taken to disinfect those who had acted as bearers.

These facts are given in some detail because they seemed to bear a sequel, for thirteen days afterwards (the ship having escaped quarantine at Suez, Port Said, and Malta) a young Lascar fireman was struck down by symptoms which soon left no doubt that he was suffering from small-pox. The coincidence of this lapse of time—corresponding so closely to the usual period of incubation—with the onset of his symptoms seemed to point to the burial service on deck as a loophole in the disinfectant precautions. This was all the more disappointing as the danger of its being so had been clearly recognised, and though the service seemed inevitable great care had been taken to isolate the participants in the service from the deceased as far as possible. Fortunately for the sequel, this second case was of a much milder type and made a good recovery on reaching the Thames.

Glasgow.

FURTHER NOTE ON THE TREATMENT OF TAPEWORM.

BY LESLIE OGILVIE, B.Sc., M.B. EDIN., M.R.C.P. LOND.,
PHYSICIAN TO THE PADDINGTON-GREEN CHILDREN'S HOSPITAL.

IN THE LANCET of Aug. 4th, 1894, I contributed a note on the Treatment of Tapeworm. As six cases—two children and four adults—which I have since seen had been previously treated unsuccessfully I venture to think that my further experience may be of interest. The line of treatment indicated in my previous communication was successfully followed in all of these cases, but I desire to refer to two of them as they appear to me to corroborate the views I then expressed as to the necessity of preparing the patient before administering the vermifuge and the absence of danger in giving the considerable doses of the liquid extract of male-fern which I recommended if it is speedily washed from the bowel.

CASE 1.—The patient was a little girl aged seven years who had undergone treatment many times during three years, but without success. She had been given repeated small doses of about fifteen minims of the liquid extract of male-fern, and although numerous segments of the worm were passed after each course of treatment they re-appeared in the stools in two or three months, when the child herself would again ask for "fern," as she felt sick and irritable and had abdominal discomfort. The child dreaded the administration of the drug as it always made her so ill for some days, but she preferred this to the unpleasant sensations produced by the presence of the parasite. The medical man in attendance was afraid to give the large doses recommended by me—one drachm at 8 A.M. and another drachm or half a drachm at 9 A.M.—as he argued that if fifteen

Digitized by Google

minims produced such severe toxic effects six or eight times that dose would be dangerous. As I previously pointed out this is exactly contrary to my experience. The small doses produce toxic effects because they remain in the bowel and are to some extent absorbed, while the large doses are sometimes expelled from the bowel within two hours of being taken, frequently before the final dose of castor oil has had time to operate. In this case I was not given time to follow thoroughly the few days of preliminary treatment by means of saline purgatives, and as, unfortunately, the child was especially constipated I had no means of properly gauging the amount of purgative required to evacuate the bowel with certainty. Without having the bowels satisfactorily moved by the evening and early morning doses of sulphate of magnesia and jalap I gave a drachm of the liquid extract at 8 A.M. followed by forty-five minims in an hour. As the castor oil given two hours afterwards failed to operate enemas were freely used and another dose of oil was administered about two o'clock. The entire tapeworm, including the head, was passed between four and five o'clock, together with a considerable quantity of mucus. The child had not suffered from the sickness, faintness, or other toxic effects which she always experienced after the small doses, but an erythematous rash appeared on the skin of the face and body in the evening, showing that some of the poison had been absorbed. She, however, felt well, ran about all day, and shared in the delight of her mother in having got rid of the enemy. I feel convinced that if I had insisted, as I usually do, on having the bowels freely opened for several days before administering the vermifuge, and if an effectual dose of castor oil had been given afterwards, the rash even would not have appeared. This case, therefore, shows the importance of procuring free evacuation of the bowel both before and soon after treatment by the vermifuge and, I think, goes far to establish the fact that effectual doses produce no more toxic effects than small inefficient doses, even though administered without the careful preparatory and subsequent measures I advise.

A case of exanthema after the use of extractum filicis maris ætherеum is reported by von F. Schmey.[1] The case was that of a broken-down old woman who, after taking ten grammes of the preparation, suffered from redness and swelling of the eyelids which spread to the cheeks and forehead and disappeared entirely in three days. Von Schmey thinks that the effect was perhaps due to the simultaneous administration of castor oil, in which filicic acid, the poisonous principle, is easily soluble. I certainly think that the castor oil should not be given along with the male-fern, because an ineffectual dose would lead to the poisonous symptoms above noted, and an efficient dose would wash the poison from the bowel before it had time to injure the worm. If an efficient dose is given two hours afterwards the solubility of the poisonous principle in the oil would facilitate its removal from the bowel.

CASE 2.—I was careful in this case, that of a middle-age woman with symptoms of obstinate constipation, to prescribe a course of purgatives for two weeks. The aperient which suited best in this case was Hunyadi Janos which she took for about a week with excellent results and no discomfort. As I previously pointed out, saline aperients are the best for the preparatory treatment as they rid the bowel of the excess of mucus which is present in most cases of tapeworm and thus expose the worm to the full action of the poison. It is more effectual to administer castor oil with jalap after the vermifuge because this combination is more rapid in its action, the object being to remove the poison from the bowel before it is absorbed, and the worm before it has time to recover and re-attach itself to the mucous membrane. In this case, after the course of medium doses of Hunyadi Janos every morning for a week, she had a dose of sulphate of magnesia and tincture of jalap one night followed by Hunyadi Janos in the morning at 7 A.M., the drachm doses of the liquid extract of male-fern at 8 and 9, and castor oil with tincture of jalap at 11 o'clock. The worm was passed along with much of the liquid extract between 9.30 and 11 o'clock, therefore before the oil was given; but, notwithstanding this, I gave the dose of castor oil and jalap to make sure that all the poison was removed from the bowel. The patient did not feel any ill effects from these apparently severe measures; in fact she suffered less than she had done on four previous occasions when she was unsuccessfully treated for tapeworm. It may be, of course, that the assurance that she was free from this parasite for ever made her minimise her sufferings.

A CASE OF MALARIOUS FEVER.

BY SURGEON-LIEUTENANT-COLONEL E. LAWRIE, M.B. EDIN.,
RESIDENCY SURGEON, HYDERABAD, DECCAN.

THE following case of malarious fever occurred in a medical student of the local medical school, who has just finished his curriculum and has been under my observation for five years. In his recollection and in mine he has never had fever until last September, when crescents were discovered in his blood the day after the first attack commenced. He always lived in the city of Hyderabad, but a month before he got fever he changed his residence to a malarious suburb called Troop Bazaar, and he has had fever about once in two months since. The last attack took place at the end of March, 1896. He was cured with quinine, and when he got well was directed to have his blood examined every day until the onset of the next attack—the attack under report,—in order to enable us to determine whether the presence of Laveran's bodies in the blood precedes or follows the disease. Accordingly, the microscope examinations of his blood were made daily, and no Laveran's bodies were found from April 8th to 30th inclusive. On the morning of April 30th he looked poorly and complained of pain and uneasiness in the region of the spleen and liver. The blood on this day was thoroughly examined by three competent observers and nothing abnormal was detected in it. He went home at 10 o'clock A.M., and at noon had very violent ague followed by the usual hot and sweating stages of intermittent fever. Next morning Laveran's bodies were found in the blood. He was kept under observation without quinine till May 4th, when we gave it to him, and he has had no fever or Laveran's bodies in the blood since and is now (May 7th) quite well. The following table shows the dates of the attacks of tertian ague, the results of the blood examinations, and the dates on which he took quinine, from April 30th to May 6th, 1896.

Table showing the relation between Intermittent Fever, Laveran's Bodies, and Quinine in the Case of a Patient attacked with Ague and Fever on April 30th, 1896.

Date.	Laveran's bodies.	Fever.	Quinine.
April 30th ...	None found at 9 A.M.	Came on with ague at noon.	None.
May 1st ...	Intra- and extra-corpuscular "swarming."	None.	None.
,, 2nd ...	Same as on May 1st; but leucocytes also "swarming."	Came on with ague at 11 A.M.	None.
,, 3rd ...	Same as on May 2nd.	None.	None.
,, 4th ...	Same as on May 3rd; rosettes.	Came on with ague at 8.30 A.M.	Ten grains at 10 A.M. and five grains at 4 P.M.
,, 5th ...	None.	None.	Five grains at 10 A.M. and five grains at 4 P.M.
,, 6th ...	None.	None.	Same as on May 5th.

In this case there were no Laveran's bodies in the blood before the disease began; they did not appear until after it was established and they were obviously one of its effects and not its cause. The bodies seen daily in the blood between May 1st and 4th bore signs of the well-marked relationship of Laveran's bodies to the white blood-cells to which I called attention in the address I had the honour of delivering before the profession in Bombay on April 4th last. Additional evidence in this direction was furnished unexpectedly by the rosette forms which were found in the blood on May 4th. One of these bodies was traced from its origin to its termination. It appeared first like a red blood-cell with a spot of black pigment in the centre. A number of small cells then made their appearance in the form of a rosette round the central black spot

Digitized by Google

and went through the changes depicted in Figs. 5, 6, 7, and 8, Plate II., of Mannaberg's work except that the small cells were devoid of nuclei. The parent cell-wall was no longer visible and fourteen separate little cells, clustered round a clear black-looking cell—the original (?) pigment,—were left naked on the field. They now resembled Edington's diagrams of discharged blood-plates. While we were wondering if we should see each of these cells go off and lead an independent existence the original cell-wall re-appeared and enclosed them all in its interior again. They then gradually faded away and nothing remained but the original cell with a black fluffy spot in the centre. The rosette, instead of being, as the plasmodists declare, a "sporulating parasite," is thus shown to be nothing more than a transition form of the extra-corpuscular Laveran's body. The transition is analogous to changes which occur in the white blood-cell when, for example, its granules are shed and its cell-wall, after becoming invisible, reappears and encloses them again just when they seem to be about to enter upon an independent life. The most remarkable and suggestive point in the changes which the rosette body undergoes under the microscope is that before the rosette appears in the cell it looks like a red blood-cell, whereas afterwards it has more the appearance of a leucocyte.

THE PRACTICAL APPLICATION OF "X" RAYS TO SURGERY AND SURGICAL TEACHING.

BY WILLIAM TURNER, M.B., B.S. LOND., F.R.C.S., ENG.,
SURGICAL REGISTRAR TO KING'S COLLEGE HOSPITAL AND SURGEON TO THE SEAMEN'S HOSPITAL, ATTACHED TO THE BRANCH HOSPITAL.

BY the kind permission of the Surgical Staff of King's College Hospital I have been enabled, during the last few weeks, to do some experimental work upon cases in the wards and outside with my "x" ray apparatus, and I find that the practical application of the process to surgical work may briefly be grouped under three headings, thus—(1) to the finding of foreign bodies; (2) to general bone surgery, especially fractures; and (3), though perhaps the most important, to surgical teaching. I will content myself for the present with giving merely one or two cases in point.

1. The Finding of Foreign Bodies.

A woman aged twenty-two years ran a needle into her right hand close to the pisiform bone in August, 1894; a portion of it was removed directly after the accident, but it was thought that a piece was left behind in the hand. Pain and swelling of the hand and arm followed, but no abscess formed and no further indications as to the position of the needle were discovered. She had two or three such attacks, and in August, 1895, a year after the accident, she, for the first time, noticed that the thumb became swollen and painful and occasionally the joints (interphalangeal and metacarpo-phalangeal) were locked; these latter attacks were recurrent usually every three or six weeks and lasted about three days, and in consequence she was prevented from making any use of the hand. I saw her on April 27th, 1896, and found that there was swelling of the right thumb from the head of the metacarpal bone to the tip of the terminal phalanx, more marked on the palmar aspect. The swelling might be best described as an indefinite thickening evidently corresponding to the sheath of the flexor tendon; there was no creaking on movement, and the movements of the joints were normal and caused no pain. No trace of a foreign body could be felt. I asked Mr. Cheatle to see her and he agreed with me that there was no indication that a foreign body was the cause of the trouble and that, unless such was proved to be present, he would not recommend operation until other treatment had failed. I then examined it with the cryptoscope, and finding the condition as shown in the illustrations given below, photographed the thumb in two positions. Fig. 1 was taken with the palmar surface of the thumb on the plate, so the shadow of the needle is shown *through* the first phalanx. Fig. 2 was taken with the radial side on the plate, the hand being fully pronated. Exposure in each case was one minute. These photographs show very well the use of taking them in different positions so as to determine the exact position of the needle in the body. Two days later I cut down and opened the sheath of the long flexor and on hooking aside the tendon found the needle lying between it and the bone, as I had expected, and removed it. In this case a definite opinion as to the cause of the trouble was impossible to be formed without the use of the "x" rays unless after an

FIG. 1.

Needle shown through phalanx. The palmar surface of the thumb was on the plate. Exposure one minute.

exploratory incision, which is neither easy to obtain leave to do from the patient or friends nor always satisfactory from the surgeon's point of view.

I wish to emphasise the fact that in many cases of needles in the body, &c., it is quite unnecessary to examine them

FIG. 2.

Side view of thumb; the hand was pronated, so that the radial surface was on the plate. Exposure one minute.

with the cryptoscope or obtain a skiagraph of them, as they are obvious to the touch of the surgeon, and so there is no need, except for demonstrating purposes, to waste time over them; and also the fact that, although one can readily

Digitized by Google

obtain skiagraphs of a part with a needle in it, it does not necessarily mean that the said needle will be always found by the operator with the same ease. This has been well shown in a case now under treatment at the hospital. A woman aged twenty-six years was sent up from the country on April 29th, 1896, having trodden upon a needle ten days previously. On the sole of the foot a mark was found just internal to the base of the fifth metatarsal bone and on a level with the spur of that bone deep tenderness could be easily elicited and the patient was unable to walk and do her work on account of pain. The cryptoscope having shown that a needle between a quarter and half an inch long was present photographs were taken in two positions and these apparently showed the needle in an accessible position. However, an exploratory incision down to the spot failed to reveal any indication of it, so the wound was sewn up and re-photographed. Finding the needle in the same position experiments were conducted with a skeleton foot on the screen and the same shadows were found to be produced by a needle lying in the sheath of the peroneus longus, so the wound was opened and the sheath and tendon carefully explored, but no trace of the needle was found. The foot was then photographed in four different positions with a guide needle placed in the wound and the relationship of the two thus determined, and a third operation was undertaken, but was equally unsuccessful. The skiagraph taken after the wounds were healed reveals the needle still in the same position. This case shows very clearly the great difficulty which may be experienced in removing a foreign body when one has the shadow only to work from.

Since these cases I have been successful in obtaining a skiagraph of a bullet of which no indication by external manipulation could be obtained. The man had shot himself, and the wound of entrance was over the fourth intercostal space about one and a half inches to the left of the left nipple. A probe passed back and slightly upwards for about three inches and appeared not to enter the chest, but to skirt the ribs. On admission the patient had no symptoms of wound of the lung, but there was a slight trace of dark blood in some sputum eighteen hours afterwards. The apparatus was all put upon a trolley with indiarubber wheels and wheeled into the ward to the bedside, and the plate being adjusted behind the left shoulder without moving the patient, with a fifteen minute exposure a skiagraph was obtained showing the position of the bullet external to the ribs, lying close to the axillary border of the scapula. This case is interesting, as it shows that the bullet does not lie in a dangerous position.

(To be continued.)

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF STRANGULATED FEMORAL HERNIA.

BY CLARKE WAKEFIELD, M.D. BRUX., F.R.C.S. EDIN.

THE following case seems to me to present several features of interest. A spinster aged sixty-nine years was first seen on April 13th at 11.30 P.M. The history was that she had worn a truss for thirty years without discomfort. During the last six months she had noticed that the hernia had increased slightly in size, but she had had no pain until the 12th at about 7 P.M. The pain gradually increased and the patient began to vomit. Late at night on the 13th, on examination I found a tense nodular hernia as big as a large horse-chestnut. The patient was retching violently and brought up some distinctly stercoraceous vomit. Her countenance was pinched and pale, her pulse thin and wiry. I tried gentle taxis, but from the history of the case and the rapidity with which the symptoms had come on I deemed it wise not to persevere with the attempts to reduce the hernia in this way. An hour after seeing the patient Dr. G. N. Adams kindly gave ether for me and I proceeded to operate. The operation was comparatively simple as the patient was very thin, the sac being exposed without any vessel requiring to be ligatured. On opening the sac some dark sanious fluid escaped, and a knuckle of bowel, which appeared by lamplight to be black, was exposed. The bowel had not lost its lustre and I decided to return it; this was easily done after incising the base of Gimbernat's ligament. It seemed wiser, in view of the deeply congested state of the gut (a piece of small intestine), not to attempt a radical operation or even ligature the neck of the sac, so I contented myself with removing a piece of omentum which was adherent to the sac and closed the upper three-fourths of the incision with catgut sutures. The temperature remaining normal the wound was not dressed again till the fifth day, when it was dressed for a reason which will presently be given. To return to the course of events following the operation. She vomited six times, and the bowels acted twice with loose motions early on the day after the operation. There was no vomiting on the second and third days, but on the fourth there was an attack of tympanites accompanied by frequent vomiting of bile-stained fluid. On the fifth day, these symptoms continuing, I gave a turpentine enema and changed the dressing to see whether anything to account for the symptoms could be seen in the wound, which, however, I found had healed by first intention. Eight hours after the enema was given she passed a scybalous motion, and from that time the recovery was uninterrupted. I last saw her a month after the operation; the patient was up and about, the scar was quite sound, and there was no impulse on coughing.

Remarks.—It is hardly necessary to remark on the insecurity of a person who wears a truss over an irreducible omental hernia, as I presume was the case of this patient for the thirty years during which she had worn the truss—a hollow Coles's truss. Perhaps the chief interest of the case rests in the attack of tympanites and vomiting mentioned above. Seeing that this attack ended suddenly after a large quantity of scybala had been passed there is little doubt that it was due to a temporary block in the large intestine.

Ladbroke-grove, W.

NOTES ON THE TREATMENT OF MEASLES.

BY A. DUNLEY OWEN, M.R.C.S. ENG., L.R.C.P. LOND.

DURING the early months of this year an epidemic of measles of a severe type visited Northampton and the surrounding district, and there was an unusually high mortality from this disease, chiefly, I believe, from concurrent bronchial and pulmonary inflammations. Of the cases that fell to my share I took notes of over 300 with a mortality of only 4, of whom one died from capillary bronchitis three hours after I was first called in, and the others were under two years old and succumbed to broncho-pneumonia. I attribute this low rate of mortality to the method of treatment I have invariably adopted—namely, to order jacket poultices, changeable every three hours, as soon as any indications of measles show themselves and before the rash appears, and I think this has been beneficial, for death has only occurred in those cases in which the mother discontinued the poultices after the first application, or, as in one case, thought proper not to poultice at all. The only medicinal treatment adopted has been ipecacuanha wine with acetate of ammonia, with a boric acid wash for the eyes in those cases which were complicated by catarrhal inflammation of the lids. Stomatitis occurred in about one-half of the cases and invariably yielded to the application of a saturated solution of chlorate of potash to the inside of the mouth, the children being too young to use a mouth wash.

I venture to think that these notes may be of some slight interest, as all the cases noted were of a severe, and some almost of a malignant, type, the slighter ones being passed over. Convalescence proved slow in nearly all the above cases; curiously, though, the town children gain strength far quicker than those in the surrounding country districts, possibly owing to the higher wages of the town workers procuring for their children a more generous diet.

Northampton.

CONGENITAL LUMBAR HYPERTRICHOSIS AFFECTING TWO SISTERS.

BY L. A. PARRY, M.B., B.S. LOND., F.R.C.S. ENG.

THE following examples of a not very common abnormality may be of interest to the readers of THE LANCET. The subjects are two girls, the third and seventh children of a family of seven; the remainder are not

Digitized by Google

affected. The hirsuties dates from birth in either case. Both parents are English. The condition of the elder child as an infant was identical with that of the younger at the present day. The elder of the two girls, aged ten years, has in the lumbar region a triangular patch, base upwards, of fine silky golden hair; the base of the triangle reaches a level one inch above the highest point of the iliac crest, and the apex is one inch above the gluteal cleft. The hair, which is directed downwards, is of a slightly lighter colour than that of the scalp and attains a length of five inches; there are no mental defects. The younger patient presents the same condition as her sister, but in a much less degree. The elder is the subject of old infantile paralysis of the right leg, giving rise to local peripheral gangrene and talipes equinus. There is no sign of spina bifida or perforating ulcer, as in the cases referred to by Mr. Bland Sutton in THE LANCET of July 2nd, 1887.

ST. GEORGE'S HOSPITAL.

A CASE OF PERFORATED GASTRIC ULCER TREATED BY LAPAROTOMY; RECOVERY.

(Under the care of Mr. C. T. DENT.)

COMPARATIVELY few cases have hitherto been published of the successful treatment by laparotomy of this formidable complication of a somewhat common disease. It seems, therefore, desirable to place this one on record, as showing that perforation of a gastric ulcer is not necessarily fatal if skilled assistance is obtained and the opening promptly sutured. It also affords a good example of the promptitude of the medical attendant in recognising the occurrence of a perforation before peritonitis has set in and the necessity for surgical interference. The chief points in this case are the occurrence of a perforation on the posterior aspect of the stomach and the oblique line taken by the perforating ulcer. It has been calculated that only 2 per cent. of ulcers of the posterior wall perforate.

A spare, anæmic woman aged twenty-six years who had suffered from indigestion for many years was admitted into St. George's Hospital on Nov. 19th, 1895. On one occasion three years previously she had had a tolerably profuse attack of hæmatemesis which came on suddenly at night. At 4.30 P.M. on the day of admission she was seized with sudden and severe epigastric pain which developed shortly after she had been moving some heavy boxes. She felt sick and, with the idea of relieving her symptoms, drank some hot water. This made her pain worse. Shortly after taking the water she vomited it all together with some half-digested food. As she had not eaten anything for some hours previously it was evident that her gastric digestion was very slow. She was seen shortly after the onset of the attack by Dr. Roxburgh Fuller, who, recognising the probability of perforation, sent her at once to the hospital for operation, acting thus with a promptitude all too rare in such cases, but to which she probably owed her recovery. The patient had for some time previously been suffering from menorrhagia. When seen directly after admission she complained of intense epigastric pain. The abdomen was rather distended and there was tenderness in the epigastric region. There were considerable difficulty of breathing and cardiac distress. The apex beat was an inch or an inch and a half higher than natural. The resonance in the left hypochondriac region was very marked and gave a higher note than natural. There seemed to be little doubt that the patient was suffering from the effects of perforated gastric ulcer. Judging by the physical condition of the abdomen it was thought that the ulcer was on the posterior wall of the stomach. The operation was at once undertaken, between six and seven hours after the first onset of acute symptoms. Mr. Dent opened the abdomen in the median line above the umbilicus, an incision which in such cases appears to him on the whole to answer as well as any other. The peritoneal cavity contained some opalescent fluid of acid reaction; but there was no undigested food free in the cavity, so that presumably the perforation was a small one. The fluid was, as usual in cases of perforation on the posterior wall, chiefly in the left hypochondrium. Even at this early stage moderately firm adhesions had formed, limiting the characteristic cavity formed by the diaphragm, the falciform ligament, and the stomach. There was a slight amount of lymph on the under surface of the diaphragm and on the posterior surface of the stomach, and such coils of intestine as presented were of bright colour and injected, with their surfaces slightly roughened by lymph. Some tolerably firm bands of peritoneal adhesions about the stomach suggested previous trouble; one of these bands, passing obliquely, compressed the stomach very markedly. After separating the adhesions Mr. Dent was able to expose the posterior surface of the stomach. There was no gap to be seen. Midway between the greater and lesser curvatures and towards the pyloric extremity was a thicker and rougher deposit of lymph extending over an area of the size of half a crown. A probe passed into this rough surface entered a sinuous track but did not appear actually to enter the stomach. The operator of course avoided making more than the very lightest pressure. On grasping the posterior wall of the stomach between the fingers and thumb an indurated area of about the size of a five-shilling piece, circular and with well-defined edges, was readily felt. The rest of the stomach was fairly healthy. It seemed probable, therefore, that a small perforation had taken place at some point in this indurated area, probably about the centre. Mr. Dent therefore passed sutures through the muscular and serous walls of the stomach on either side of the indurated portion and sewed the two re-duplications over the induration. The cavity which contained the fluid that had escaped from the stomach was irrigated with hot boracic solution until the injection returned quite clear. No drainage-tube was employed. The patient vomited once after the operation. She was placed in bed with the head and shoulders well raised—a position which Mr. Dent considers to be of the greatest importance in all such cases and especially where, as in this instance, the heart's action is impeded by abdominal trouble. After flushing out the peritoneal cavity, especially after a long and tolerably exhausting operation on a heated operation table, patients are prone to break out into very profuse perspiration and, if not very carefully watched, run some risk of chill. The sweating may be largely obviated by sponging out the peritoneal cavity until nearly dry; but this seems to Mr. Dent an undesirable practice and one that prolongs the operation unduly. In such cases his usual practice is to avoid all linen clothing next the skin and to direct the nurse to rub over the limbs and the whole surface of the body gently and constantly for a couple of hours, if need be, with soft, warm towels. The effect of this very mild massage not only prevents any chill but constantly sends the patient off to sleep; and the rubbing may even be persevered in with advantage, if very gently done, during actual sleep. For the first twenty-four hours the patient was kept on nutrient enemata and suppositories. After that small quantities of food such as peptonised beef-tea, milk, chicken broth, and the like were given by the mouth. The day after operation there was considerable distension, obviously of the colon, and the temperature ran up a little, but the trouble passed away at once after an enema rutœ had been given with a long tube. The highest temperature was 100·2° F. on the second day after operation. After this the temperature fell to normal and remained so. Throughout the patient was kept well raised in bed and turned on to her right side with the idea of keeping the food away as much as possible from contact with the ulcerated surface and favouring its passage through the pylorus. In all gastric operations the patients will do better if they are kept well raised in bed from the first, and in cases of pyloroplasty Mr. Dent has seen vomiting at once checked by merely raising the patient. Save for a little stitch-hole suppuration the recovery was uninterrupted. Such suppuration, which merely signifies the separation of minute sloughs owing to the pressure of the stitches, is almost invariable, he thinks, when there is any degree of

Digitized by Google

distension after laparotomy. The apex beat gradually came down towards the normal, but was above the usual point even when she left the hospital. Almost from the first the patient exhibited considerable intolerance of any form of milk. Benger's food was found to answer well. The patient was seen a few months after operation. She was then in good health and made no complaint of digestive troubles.

Remarks by MR. DENT.—There is little to be said about a case such as this, which presented really no complications. The chief credit is really due to the medical man who recognised the symptoms so promptly and allowed no time to be wasted. It was quite clear from the condition of the abdomen that in a very few hours the case would have been a very much more formidable one for the operator. As it was I cannot but think that she only just escaped the lung complications which have led to a fatal issue in so many cases which have been operated on. In this instance as the woman was not much exhausted I delayed giving any food by the mouth for twenty-four hours, but I would not hesitate to give food by the mouth almost immediately after operation if there is much exhaustion. I do not consider that "physiological rest" of the stomach is practically so complete when all food by the mouth is absolutely withheld as when small quantities of easily absorbable materials which are likely to pass readily on into the intestine are given. In this case milk did not seem to be such a food, and I think this will often be found the case. I believe it to be also very important in these cases, as in those of strangulated hernia, to bring about action of the bowels as early as possible. The idea that we are resting damaged intestine by allowing accumulation to take place in it and distention to occur is unsound, and the accumulation that will take place in such cases even when apparently next to no food has been taken for a long time, and where constant vomiting possibly occurs, is surprisingly great. Physiological rest of the intestine is best secured when the natural functions of the intestine are being discharged as nearly as may be in the normal manner. In the museum of St. George's Hospital are several specimens illustrating a condition similar to that which I believe existed in my patient. The track of perforation is often sinuous and of considerable length when it passes obliquely through the coats of the stomach.

SUSSEX COUNTY HOSPITAL.

A CASE OF PERFORATED GASTRIC ULCER; LAPAROTOMY; RECOVERY.

(Under the care of Mr. R. F. JOWERS.)

IN THE LANCET of March 2nd, 1895 (Mirror of Hospital Practice), we published the notes of a case of successful operation after perforation of a gastric ulcer, which was also treated at the Sussex County Hospital and by the same surgeon. We are pleased to place the account of this somewhat similar case before the readers of THE LANCET. It may be recollected that in the other instance alluded to a woman aged twenty-four had suffered from dyspeptic symptoms for two years, symptoms of perforation came on six hours before the operation, when an ulcer on the anterior aspect of the stomach was found, drawn into the wound. and sutured with some difficulty. Symptoms of collapse on the twelfth day led to a re-opening of the wound, but nothing wrong was found, and afterwards the patient got rapidly well. Mr. Jowers appended to his case a list of those which had been subjected to the operation, twenty-five in number, with success in about 35 per cent. So many have been recorded since that the list is far too long for the space at our disposal. For the following notes we are indebted to Dr. Hood, assistant house surgeon.

On the evening of Feb. 10th, 1896, Mr. Jowers was asked by Mr. Baines to see a patient to whom he had just been called and in whom he had diagnosed perforated gastric ulcer. She was a somewhat anæmic but well-nourished girl aged nineteen years. Between two and three months before admission she first felt pain after food in the left side and between the shoulders, lasting about an hour. This became gradually worse, until in a month's time she had great tenderness all over the left hypochondriac region, so that she was obliged to remove her stays in the evening. This continued till the date of admission, but during the whole time she had never vomited or brought up blood. On the afternoon of the day of admission (Feb. 10th,) she was out shopping. About 5 P.M. she had her usual meal of tea and bread-and-butter and again went out. On returning two hours later she was seized with sudden acute pain over the whole abdomen and faintness. The pain was so severe that she lay "doubled up," groaning, and unable to bear being touched. She was given some brandy, which made the pain worse, and then some peppermint, which was almost immediately vomited. There was no blood in the vomit. When first seen by Mr. Jowers about 8.30 P.M. she was extremely collapsed and in intense pain, the slightest movement or touch causing her to scream out. She was supported by pillows so as to relax as far as possible the abdominal muscles, and the knees were drawn up. The abdomen was fixed, scarcely moving with respiration, but there was no marked distension. At this time there was no loss of liver dulness. The pulse was feeble and rapid. It was decided to give her a hypodermic injection of morphia at once and remove her as soon as possible to the hospital. On her admission she was in much the same condition, except that the liver dulness had disappeared and the abdomen was slightly distended. Before being taken to the operating theatre an enema of milk, beef-tea, and brandy was given and ether administered. Mr. Jowers, assisted by Dr. Black, made an incision in the median line, commencing just below the xiphosternum and continued vertically downwards for about three inches. An unusually thick layer of sub-peritoneal fat was met with. On opening the peritoneum a small quantity of free gas escaped with a strong odour of peppermint. The stomach presented at the wound and was carefully drawn forwards and examined; some recent lymph was noticed on its surface and on the edge of the liver. A perforated ulcer rather smaller than a threepenny piece was found on the anterior wall at the cardiac end near the entrance of the œsophagus. By means of two silk sutures passed through the outer walls of the stomach at some distance from the ulcer the latter was brought well into the abdominal wound. Gauze was packed around and a tube passed through the ulcer into the stomach, some greenish fluid escaping smelling strongly of peppermint. An attempt was then made to wash out the stomach through the tube, but it proved unsatisfactory owing to the tube getting blocked by solid food. The edges of the ulcer were then pared by two curved incisions leaving an elliptical opening about an inch in length which was closed by two rows of Lembert's sutures of very fine silk. The abdomen was thoroughly flushed with hot water, the washing being continued till the water returned quite clear. The abdominal wound was closed with salmon-gut sutures, a glass drainage-tube being inserted at the lower end, and cyanide gauze dressing was applied with a Keith's rubber dressing surrounding the tube. On the 11th the patient was sick twice during the night, bringing up undigested food smelling of peppermint. At 7 A.M. the patient was drowsy with contracted pupils, being still somewhat under the influence of morphia; the pulse was 130 and feeble, the respiration was 56, and the temperature was 101° F. The abdomen was scarcely moving and generally tender. She had passed urine. Nutrient enemata of milk, beef-tea, and brandy had been given every four hours, but nothing by the mouth. The patient was ordered half a pint of coffee with an ounce of brandy per rectum. At 4 P.M. the temperature was 100·4°, the pulse was improving, and the abdomen was beginning to move. By means of a glass syringe and tube a little flaky turbid serum had been drawn out of the drainage-tube four times. She had suffered a good deal of pain and had an anxious facial expression. Twenty minims of tincture of opium were given in a nutrient enema at 4 P.M., at 8 P.M. a hypodermic injection of three minims of morphia solution, at 12 midnight fifteen minims of tincture of opium, and at 4 A.M. ten minims in a nutrient enema. On the 12th the pain and general tenderness were much relieved, the abdomen was moving fairly, and the facial expression had become much more cheerful. She was sick once at 4 A.M. with green bilious vomit. The pulse was 108, the respiration 28, and the temperature 98 6°. The patient had had her mouth washed out but had swallowed nothing since the operation, but she had retained the enemata. No flatus had been passed since the previous day. About a drachm of flaky and slightly turbid serum was drawn up from the drainage-tube. The abdomen being slightly distended, an enema of turpentine and gruel was given at 3.30 P.M. She

Digitized by Google

was sick several times and had a good deal of pain. On the 13th, however, she had no pain or tenderness, the abdomen was moving well, and there was no sickness, the patient passing flatus freely. The bowels were opened loosely four times. The pulse was 110, the respiration 20, and the temperature was 99·4°. The serum drawn up from the drainage-tube being quite clear the tube was withdrawn and the stitch, inserted for the purpose at the time of operation, was tied. Small pieces of ice were given by the mouth. On the 14th the patient was going on well. A teaspoonful of hot water was given by the mouth every half-hour when the patient was awake. The nutrient injections were continued. On the 15th two teaspoonfuls of peptonised milk and beef-tea were given alternately every half-hour and increased to a tablespoonful at 12 noon. There was no pain or sickness. On the 16th the patient's food was increased to one ounce of milk and beef-tea alternately every hour. Her temperature was 99°, the pulse 80, and the respiration was 24. There was still no pain or sickness. Nutrient enemata were administered every six hours. Two stitches were removed. On the 19th the remaining stitches were removed, the wound being quite healed. An egg beaten up in peptonised milk was ordered. The nutrient enemata were continued till March 3rd, and fluid diet was continued till the 9th, when boiled fish was given. Owing to the patient's dislike for fish minced chicken was substituted next day. This, with milk pudding, custard, &c., was continued until she left the hospital quite well on the 26th. On April 10th the patient reported herself in the out-patient room and said she had no pain or sickness. She appeared to be in excellent health.

Remarks by Mr. JOWERS.—This was a case presenting no great difficulties to the operator. The ulcer was situated anteriorly and towards the cardiac end and was easily reached. The way in which the liver dulness varied is noteworthy, for though there was nearly complete absence of liver dulness when the patient was seen in bed just before removal to the theatre it appeared to be normal when she was fully extended under the anæsthetic on the operating table, a fact which can only be attributed to the change in position. As not infrequently happens in perforating ulcer, either of the stomach or duodenum, there had been no previous vomiting or hæmatemesis. To the fact that a prompt diagnosis was made by Mr. Baines and that she was thereby enabled to be operated upon some three and a half hours after perforation the satisfactory result may be attributed.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Splenic Anæmia.

THE last ordinary meeting of the present session took place on June 9th, Dr. W. HOWSLIP DICKINSON, President, being in the chair.

The PRESIDENT made brief allusion to the losses which the society had sustained since the last meeting by the deaths of Sir J. Russell Reynolds and Sir George Johnson, the former of whom, he said, was distinguished by his culture and his learning and the latter had been one of the main supports of the society during the greater part of his career, had once been President, and most of his work had seen the light in the society's Transactions.

Dr. SAMUEL WEST read a paper on a case of Splenic Anæmia (spleno-megalic primitive) and gave an account of the disease. The patient was a man aged thirty-six who came to hospital suffering with extreme anæmia, high temperature, and a large spleen. The examination of the blood proved that it was not a case of leucocythæmia. The illness began twelve months previously with profuse bleeding after extraction of a tooth, from which time the patient had been getting weaker and weaker, and had lost much weight. He suffered frequently from epistaxis. On his admission the patient was described as looking cachectic and very ill, and extremely pale, with a flush on the cheeks; the temperature, was 103° F. He was spitting some blood-stained fluid, but it appeared to come from the gums. There were no conditions in the chest or other parts of the body, excepting the abdomen, which anæmia would not account for. In the abdomen a very large spleen was found which was slightly tender to the touch. Examination of the blood showed that the red corpuscles were much reduced, as was also the hæmoglobin, and though the white cells were increased they were not more than the fever would account for. It was obviously not a case of leucocythæmia. A daily account of the case was given, but there was nothing special to note except the maintenance of high temperature and the progressive loss of strength. A few attacks of epistaxis occurred and there was a little bleeding from the gums. On Nov. 27th two large hæmorrhages were discovered in the retina which had not been there before. On Jan. 3rd the patient, who had been hoarse for some time, developed œdema of the larynx. The dyspnœa became so urgent on the 5th that tracheotomy had to be performed. The wound took on an unhealthy action from the first and frequent oozing took place from its surface, which on the 8th was severe enough to require plugging. On the 10th hæmorrhage broke out afresh, blood appeared to be sucked into the trachea, and the patient died in a few minutes. A post-mortem examination was made, but there was nothing notable to record except the condition of the liver and the spleen. The liver weighed ninety-three ounces; on microscopical examination the interstitial tissue was found to be slightly increased. The spleen weighed seventy-six ounces, was very soft, and contained one infarct; microscopical examination showed that there was a condition of slight cirrhosis, affecting especially the Malpighian bodies, which were decreased in size. Neither liver nor spleen gave the iron reaction. There was a form of profound anæmia, progressive in character, of no long duration, associated with great enlargement of the spleen, but without leucocytosis or enlarged glands. The disease was very rare and peculiar in its character, and therefore deserved a special name. It had been described under various names: splenic anæmia commonly, in this country; splenic cachexia, splenic pseudo-leukæmia, lymphadenoma-splenica, and also spleno-megalic primitive. There were three stages in the disease; the first, that in which the symptoms were merely those of gradually increasing weakness, with occasional pain in the splenic region; the second, where the anæmia became more marked, and the spleen greatly enlarged; and the final stage, that of cachexia and death from asthenia. It was in the second stage that most of the patients came under observation, and they were then found to suffer usually from severe attacks of pain in the splenic region, paroxysmal in character and somewhat like colic. The temperature was raised to 102° F. or more and the spleen was found considerably enlarged. The blood changes were not characteristic and were not different from those of grave anæmia of simple origin, and no parasites had been discovered. Bleeding from various parts was very common and especially from the nose, but sometimes also from the stomach and bowels. In the later stages the hæmophilic condition was usually pronounced, but the patient generally died of exhaustion. The disease appeared to be continually progressive and of comparatively short duration—twelve months or so. The diagnosis was easy but the cases were rare. The disease might occur at any age, but it was commonest in adults and in males. The causes were unknown. The morbid anatomy seemed to show that the only two organs affected were the liver and spleen. In the liver slight cirrhosis was usually found, and in the spleen also a condition of cirrhosis which affected especially the Malpighian bodies. These might be completely surrounded by fibrous tissue and atrophied. These changes in the spleen were not found in any other form of anæmia with which we were at present acquainted. The peculiarities of the present case were (1) the acute onset and short duration; (2) the hæmophilic condition which developed so early; (3) the œdema of the larynx, which necessitated tracheotomy: and (4) the elevation of temperature, which was continuous as long as the patient was under observation. The number of cases recorded was very small, probably under twenty. The claim that these cases formed a definite clinical group of anæmia must, he thought, be regarded as fully established. The case was brought forward partly on account of its interest and rarity and partly with a view to discussion of these peculiar and grave forms of anæmia.

Brigade-Surgeon-Lieutenant-Colonel KENNETH MACLEOD said that last February a child aged seven was brought to him with splenic enlargement for him to determine whether it was malarious or otherwise. The boy was born in this country of healthy parents and went over

Digitized by Google

to live in a suburb of Calcutta from 1889 to 1892, in which latter year the patient returned home. There was no history of malaria in India. In 1894 the child had attacks of fever here which were followed by sweating and there was progressive enlargement of the spleen. The result of a careful examination convinced him that the case was one of non-malarial enlargement of the spleen, but he regretted that he had made no examination of the blood. There was absence of improvement under anti-malarial treatment, so arsenic and iron had been given internally, iodine applied locally, and the patient sent to the seaside.

Dr. COUPLAND remarked that the whole point about these cases was the absence of leucocytosis. The subject was novel to a certain extent, but many physicians had seen cases of progressive splenic enlargement without leucocythæmia. He referred to the case of a married woman aged forty-three whom he had seen with Dr. Albert Wheeler of Honor Oak. There had been an attack of acute rheumatism in 1870, and after her second child was born she had a severe attack of "ague," but it never recurred. A swelling in her left side was noticed in the beginning of 1888, and in the November of the same year the spleen was considerably enlarged. There was no excess of leucocytes in the blood, and there was never any marked anæmia. She went on year by year with occasional pain and diarrhœa and she gradually sank, emaciated, dying of asthenia in November, 1890. At the post-mortem examination there was enormous enlargement of the spleen with extensive hæmorrhages into its substance; its tissue was firm. He had read Banti's paper, pointing out the advantages of splenectomy in these cases and he regretted that he did not recommend splenectomy in this case. About four years ago a woman came into the Middlesex Hospital with anæmia, weakness, and enlarged spleen. Under treatment she improved slightly and was sent home. She returned later with a relapse and Mr. Gould removed the spleen. For a year or two she improved greatly and passed into a condition of plethora. Two years later she returned to the hospital bleeding from the rectum, and some internal hæmorrhoids were removed. Six weeks ago she came back again very ill indeed, bleeding from the stomach and bowel. At the necropsy the source of the hæmorrhage was found to be varix of the œsophageal veins and dilated veins in the lower bowel. There was ascites and the liver showed evidence of advanced syphilis, the presence of which raised doubts as to the case being one of the class under review.

Dr. PYE-SMITH said that years ago Dr. Wilks had described these cases fully and carefully. Two years ago he saw a patient who was a fine healthy-looking man who had a large spleen and suffered from hæmorrhages, but there was no leucocythæmia. The case proved fatal. The natural associants of this disease pathologically were the other profound anæmias. In the whole group would be found diminution of red corpuscles, liability to hæmorrhages, intermittent pyrexia, and a fatal termination. In the treatment of them iron, quinine, and iodide of potassium proved useless; phosphorus was pernicious; arsenic occasionally did good, and the only treatment that cured was the early removal of the spleen. The relationship with malaria was not a pathological one, the resemblance being confined to the clinical aspect.

Dr. GALLOWAY referred to a case he had seen at the Great Northern Hospital with Dr. Clifford Beale. At the necropsy six or eight large, firm vegetations, were found round the aortic orifice, and a diagnosis of ulcerative endocarditis had been suggested during life.

Dr. NORMAN MOORE mentioned the case of a child under his care, a boy aged ten years, whose spleen was very much enlarged, the liver being also enlarged. There was slight ascites, and there had been one copious attack of hæmatemesis. He had been under observation for two years, and there was no leukæmia or amyloid disease and the boy had not lived in a malarious region. A cardiac murmur was present. He had thought that the condition was a form of congenital syphilis, but this was negatived by the history. He asked whether Dr. West considered the duration of the disease an essential point.

Dr. F. TAYLOR mentioned the case of a girl aged thirteen in whom the symptoms had lasted already for four years. Paroxysmal pain was first noticed on the left side and swelling shortly afterwards: a year later the patient was noticed to be anæmic. When admitted later to Guy's hospital the spleen was greatly enlarged; there were apical systolic and pulmonary basic murmurs, and the red blood corpuscles were diminished in number. No parasites were found in the blood, and the patient had not lived in a malarious district. The patient was three months in the hospital, and there was no approach to pernicious anæmia during that time. The actual increase of leucocytes was small; treatment produced no material change, and the parents declined splenectomy. The patient died after the disease had lasted four and a half years. Two years ago a medical man came under his observation who was suffering from marked anæmia. He was taken ill in November, 1893. For two years he had noticed something wrong in the left flank; he had been taking arsenic without avail, and inhalations of oxygen were tried, under which he appeared to improve. There was no excess of white blood corpuscles; there was a scaly eruption on the palm and a tender nodule on the tibia, but he did not admit having contracted syphilis. He was still alive but was not working, and so the duration of his illness up to the present was nearly four years. One important outcome of these observations was that the diagnosis of leucocythæmia was not to be made without an examination of the blood. If syphilis were a cause of enlargement of the spleen it could only operate through cirrhosis of the liver or amyloid disease. He mentioned another case which came under his care in 1893 for hæmatemesis. The patient was a lad aged sixteen who had never taken alcohol. On examination the spleen was greatly enlarged, and there was much anæmia; the blood showed no excess of white corpuscles, but the red corpuscles and hæmoglobin were both deficient. He improved and went out of the hospital. In October, 1895, he was still pale; the blood was examined and there was no leucocytosis. In February of the present year he again suffered from hæmatemesis, which rendered him very anæmic; the spleen was still enlarged and there were retinal hæmorrhages and optic neuritis. The blood was as before, but later the white corpuscles had increased in number but not sufficiently yet to justify the case being regarded as one of leucocytosis.

Dr. LESLIE MURRAY said that in certain cases there was a distinct diminution of leucocytes and there was no anæmia. He referred to a case which lasted twelve months; diarrhœa was present, which necessitated the stoppage of the arsenic, and there was occasional pyrexia with gradually progressive asthenia. The spleen weighed over 6 lb. and showed recent and old hæmorrhages and infarcts, but no cirrhosis. The liver was twice its normal size and contained minute nodules between the lobules like points of granulation tissue. The whole of the solitary glands and Peyer's patches were also enlarged. Iodide of potassium had a good effect and diminished the spleen by two inches. Another case from the same place—a marshy district of Scotland—came to him three months later, in which the fatal result was due to septic peritonitis.

Dr. KANTHACK said that he had made a mistake in the description of Dr. West's case, for there was a distinct increase of fibrous tissue in the spleen. The blood in these cases should be carefully examined and the white corpuscles catalogued according to the commonly accepted code. Cases of splenic anæmia occurred in children and adults. In children considerable leucocytosis was often present though not amounting to leucocythæmia. In adults leucocytosis was not present normally. Rachitic and syphilitic conditions in children might be associated with severe anæmia and thus a condition might be established indistinguishable from splenic anæmia. In the adult cases pathology still left them in the dark. He thought that splenectomy was not a good operation in these cases, for so far as pathological teaching went the spleen in these cases was rather a compensatory organ than the seat of the disease.

Mr. PEARCE GOULD protested against the value of splenectomy being judged by the prevailing pathological view of the disease. The cases ought to be judged on their merits, and Banti's results could not be set aside by any theoretical considerations as to the nature of the affection.

Dr. JOHN HARLEY asked whether there was any connexion between the endocarditis and the splenic affection, for several observers had noticed the coincident existence of the two diseases.

The PRESIDENT asked if there were any antecedent history of malaria.

Dr. WEST, in reply, said it would be useful to have cases like that related by Dr. Coupland recorded in the Transactions beside his own. There was no history of malaria or of syphilis. One of the cases related by Dr. Murray was

Digitized by Google

evidently Hodgkin's disease. No organisms had ever been discovered in connexion with these cases. The diagnosis of these cases was often extremely difficult and he would hesitate before adopting so heroic a procedure as splenectomy for this disease.

ISLINGTON MEDICAL SOCIETY.

Two Deaths from Coal-Gas Poisoning.—Ulceration of the Tongue and Mouth.—Uneventful Midwifery (4700 cases).—Needle in the Wrist and Roentgen Rays.—Obscure Case of Perforating Ulcer of the Stomach.

THE last meeting of this society was held at 25, Highbury-place on May 26th. The following is a brief report of the proceedings:—

Mr. JOHN T. JACKSON read notes on two cases of Fatal Coal-gas Poisoning. Two servants, the elder aged fifty-six years and the younger aged fourteen years, were in the habit of sleeping together in a small, badly ventilated bedroom without a fireplace, and in which there was a gas-bracket by the window. They were forbidden by their mistress to use the gas and were supplied with a small safety oil-lamp and a candlestick. On the morning of April 25th, about seven o'clock, as they did not appear to be getting up at the usual time, their mistress went up to their bedroom and immediately smelt a strong smell of gas, and upon their door being opened found the room full of it. One of the sons coming to her assistance opened the window and turned off the gas-tap, from which it had been escaping. Upon looking round they saw the elder patient lying half out of the bed and dead, but seeing that the younger one was still breathing they carried her into the next room, placed her on the bed, and opened the window. Mr. Jackson was summoned a little before 8 A.M. and found the woman dead, so he attended to the girl immediately. He found her lying on the bed quite unconscious, with the pupils widely dilated, the conjunctivæ injected, and the extremities cold. The face was pallid, but not dusky, neither were the lips. The breathing was quick, but not laboured, and the pulse was quick and feeble. Hot bottles were applied to the feet and legs and blankets thrown over them and mustard plasters to the chest, the heart, and the back of the neck. She was given some sal volatile and water by the mouth without difficulty. Shortly afterwards convulsions came on affecting the facial muscles, with closure of the jaws and also both arms and hands. The legs did not appear to be affected. With the assistance of another practitioner, who had also been called in, artificial respiration was performed for a time, but as there seemed to be no difficulty in breathing this was left off. Hot coffee was given per rectum, and as the convulsions still continued bromide of potassium and brandy were injected by the rectum at intervals of three hours. The convulsions were accompanied by restlessness and some moaning. There was no return of consciousness, and she remained in this condition until 6.30 P.M., when the breathing became more hurried, she coughed up blood-stained, frothy mucus, her face became covered with perspiration, and the pulse becoming more rapid she died about 10 P.M. There was no post-mortem examination. On examining the servants' room the candle was found quite burned down in the candlestick. The supposition is that the woman had been sitting up late, burnt out the candle, had lighted the gas and had not properly turned it off, or in attempting to do it had turned it slightly on when the flame went out. Similar incidents were mentioned by other members.

Dr. A. REID brought forward some notes on Ulceration of the Tongue and Mouth (stomatitis, cancrum oris, &c.), which he said were common enough in children but not so frequent in adults. A case occurred in a woman aged twenty-two years, to whom he was called on April 11th last. He found the patient (recently married) looking very ill, anæmic, and generally run down. There was a thin, quick pulse and the temperature was 101° F. The tongue was very foul and the characteristic fœtid breath of stomatitis was present. There was loss of appetite and sleep. On examining the mouth the tongue was found to have a thick, yellow fur; it was not very swollen; the gums were spongy with spots and superficial ulcerations. Nothing was observed on the inside of the cheeks. Dr. Reid ordered a calomel aperient, a mixture of chlorate of potassium, and mouth washes of chlorate of potassium and Condy's fluid to be used alternately. He insisted on a liberal supply of nourishing soup and wine or brandy. She did not improve for several days. Her tongue got more fixed and she could not articulate. He then found a slough forming along the left side of the tongue. She was unable to use the mouth washes thoroughly, so glycerine of borax was applied with a brush. The slough slowly separated and the tongue healed. Under citrate of iron and quinine with strychnine, combined with liberal feeding and painting the gums with iodine, she recovered rapidly and perfectly.

Mr. JAGO read a paper on Uneventful Midwifery (4700 cases), in which he gave the following particulars. The term "uneventful" as applied to midwifery could, of necessity, only be used in a comparative sense. How far he was justified in adopting it as descriptive of his own experience must be left to the judgment of the members. He had gathered the records of rather more than 4700 cases extending over a period of twenty-three years, the lowest number attended in one year being 19 and the highest 295. He regretted that he had not kept a methodical table of the different presentations, the use of instrumental aid, versione, &c., the cases being of no use in the matter of definite statistics. The chief "events" in Mr. Jago's practice, however, were very clear in his memory and are briefly related as follows. The main consideration in obstetrics is, he considered, the death-rate, and he had to record nine deaths. Two deaths were in cases of advanced phthisis and were not primarily due to the puerperal state. Two were from hæmorrhage, one a case of placenta prævia and the other of concealed accidental hæmorrhage. One death was probably the result of embolism and one distinctly due to privation. The remaining three cases were of septic infection. Of the last, two happened quite twenty years ago, and the third in 1892. This last case was of peculiar interest and taught a very definite lesson. The patient was a woman aged thirty-eight years with her first child. The labour was hard and instrumental, but in no way unusual. She did very well until the fourth day, when symptoms of septic infection became manifest, and she died on the eighth day after delivery from puerperal peritonitis. The child was circumcised on the same day, and on the fourth day afterwards was seized with pyrexia, sickness, tenderness in the right iliac region, tumefaction of the abdominal walls, &c., and died on the eighth day after circumcision from what Mr. Jago considered septic peritonitis. The importance of this case lies in the fact that the drains in the area of the next house (which was unoccupied) were exposed for the construction of an intercepting trap; the lying-in room was in the front of the house, and the month being July the windows were kept constantly open. Only once had he had occasion to perforate the cranium, and in this case he thought it would not have been necessary had the use of chloroform not been prohibited on account of bronchial complications. He had seen three cases of placenta prævia. In one case, as already stated, the patient died. In the second the labour was completed before his arrival, the placenta having been expelled in front of the head of the child. In the last case delivery was safely effected by the adoption of Dr. Barnes's recommendation. In all the cases the children were still-born, the period of confinement being about the eighth month of pregnancy. He only recalled one case of prolapsed funis, and in this the child was stillborn. Once only had he seen a shoulder presentation, or at least he presumed the shoulder presented. He was called to the case by a midwife, who had apparently been pulling on the arm in the hope of effecting delivery. Three times he had had occasion to induce premature labour. In one case of much interest, at the wish of Dr. Fancourt Barnes, who had removed a large ovarian tumour at the fourth month of pregnancy, labour was induced at the seventh month to prevent the weakening of the abdominal walls by the over-stretching of the recent cicatrix. Labour was induced in each by the introduction of the gum elastic catheter. He had to record two ruptures of the perineum through the sphincter ani and for about an inch up the septum. Both were forceps cases; in one the presentation was normal, and in the second face to pubis. One was repaired by the quilled suture, but the result was only partially satisfactory; in the other one deep and four superficial sutures were used, with the best results. This patient Mr. Jago had since attended in four confinements without further mishap. He had no accurate data as regards twin births, but he remembered one case in which one child had evidently died about the sixth month and

Digitized by Google

was flattened out, taking the distinct curve of the uterine cavity. These facts constituted the exceptional occurrences in his experience. If he might venture to generalise and deduce from them he should like to submit to their consideration two conclusions to which he was led. The first was that clean midwifery need not be ostentatiously antiseptic, and, secondly, that among the lower middle and respectable artisan classes variations from the normal state are comparatively rare.

Dr. GLOVER exhibited a photograph of a Needle in the Wrist shown by the Roentgen process, taken by Mr. W. P. Granville, 36, Oakfield-road, Stroud-green. It was easily removed after being in six months. He also gave particulars of a misleading case of Perforating Ulcer of the Stomach, fatal in sixteen hours from the time of his first seeing it, occurring during menstruation, the pain and peritonitis being most marked in the left ovarian region, where pain had been complained of for weeks. Death occurred from shock.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

The Climate and Mineral Springs of Bridge of Allan.

AN ordinary meeting of this society was held on May 20th in the rooms of the Medical Society of London, Chandos-street, Cavendish-square, W., the President, Dr. HENRY LEWIS, being in the chair.

Dr. HALDANE read a paper on the Climate and Mineral Springs of Bridge of Allan. He pointed out that the mildness and freshness of the climate, due to the situation of the town on a gentle slope facing south, surrounded behind and at the sides by hills, made it a suitable Scottish winter resort for many invalids, while the waters acted as a mild and safe aperient, diuretic and deobstruent and were used with success in chronic constipation and liver and glandular affections, the treatment and baths being carried on equally well in summer or winter. The baths were found useful in some cases of chronic skin diseases and rheumatism. The "Nauheim treatment" of cardiac affections was now being tested.

Dr. MYRTLE (Harrogate) considered Bridge of Allan more suitable for cases of bronchial irritation and phthisis than any other part of Scotland.

Mr. MOXON (Matlock) and Dr. GILBERT (Tunbridge Wells) considered that the change of climate and mode of life had more to do with the benefit received by patients at Bridge of Allan than the waters.

Dr. TYSON (Folkestone) said that they would do a great amount of good by placing their own health resorts in the proper position they deserved, and they did not wish to push the claims of their own health resorts to the exclusion of foreign spas.

Dr. SOLLY (Harrogate) agreed that it was certainly time to bring before the profession the advantages of their home health resorts, but in doing so they must be careful not to claim too much for any particular resort.

Dr. SNOW (Bournemouth) said that in this country they did not sufficiently minister to the needs of the minds of the visitors by providing suitable amusements. All this must be altered.

Dr. LEONARD WILLIAMS (Sidmouth) endorsed the remarks of Dr. Solly.

Mr. SHIRLEY JONES (Droitwich) also spoke and Dr. HALDANE replied.

Dr. HYDE (Buxton) then moved the following resolution:—"This meeting is of opinion that increased travelling facilities in the shape of specially reduced fares, through communication, and quicker and more frequent train services in connexion with British health resorts are desirable, not only in the interests of such resorts, but also in those of the visitors, and particularly invalids, who have to resort to the spas and watering places in search of health; and the meeting further resolves that the council be requested to appoint a committee to consider the subject with a view to influencing the various railway authorities, and taking such other steps as may be deemed desirable." He showed the disadvantages under which our home resorts laboured on account of the cheaper travelling facilities granted to visitors to continental resorts, giving numerous illustrations. He said that health resorts were not ordinary towns, that the traffic was essentially a holiday traffic, and that the fares should be reduced and other concessions and alterations made as to the length of stay, &c.

Dr. SNOW (Bournemouth) warmly seconded the resolution and said that the railway companies should be approached in the most friendly way, and he thought it would be better to do this through the Councils of the different towns.

Dr. MYRTLE (Harrogate) said that on many lines hunters, golfers, and curlers could travel for reduced fares, and visitors to health-resorts ought to be treated similarly. He pleaded for a better sanitary accommodation in all trains.

Dr. SOLLY (Harrogate) urged the necessity of providing through carriages. Many invalids refused again to face journeys on account of change and long waits.

Mr. MOXON (Matlock) thought that they should certainly lay before the railway companies the points raised by the previous speakers.

Dr. TYSON (Folkestone) was strongly in favour of each district working out its own case with the different railway authorities, because some towns had no complaints to make.

Mr. CUFFE (Woodhall Spa) said that at Woodhall Spa they had approached the railway company some years previously with the greatest success as regarded reduced fares, extended time of stay, and through carriages.

Mr. TREGELLES FOX (Strathpeffer Spa) thought that the suggested improvements would be remunerative to the railway companies, and that the society was entitled to back its propositions with a certain amount of sentimental support.

Dr. LEONARD WILLIAMS (Sidmouth) thought that a committee should be appointed, but should only exercise its influence on application from the various health resorts.

Dr. HYDE, replying, agreed that they could not do much on account of the commercial aspects, but he thought concentrated influence would be more powerful and efficient than that of individuals.

The resolution was carried unanimously.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

Syphilis Simulating Tuberculosis.—Laryngeal Autoscopy.—Instruments Used by Native Indian Oculists.—The Rôle of the Carbohydrates in Diabetes with an Inquiry into the Constitution of Infants' Food.—Primary Sarcoma of the Liver Simulating Hepatic Abscess.—Opium Poisoning.

THE tenth meeting of this society was held on June 3rd, Dr. ARGYLL ROBERTSON, President, being in the chair.

Mr. CATHCART showed a case of Syphilis Simulating Tuberculosis.

Dr. LOGAN TURNER gave a demonstration on Dr. Kirstein's method of Laryngeal Autoscopy. The principle of the method consisted in bringing the interior of the larynx and trachea *directly* under the eye of the observer without the use of the laryngeal mirror, and hence there was no reflected image. In carrying out the examination there must be a straight line between the aperture of the mouth and the interior of the larynx and trachea. This was obtained by raising the patient's head till it formed an angle of 60 degrees with the axis of the trunk. By depresing the posterior part of the tongue immediately in front of the epiglottis the epiglottis was raised and drawn forwards. The larynx and trachea were illuminated by means of an electric lamp placed in the handle of the autoscope. The instrument required some dexterity in its use, and many patients were quite unable to submit to the pressure required to depress the tongue and draw forward the epiglottis. The instrument consisted of a spatula of nickel-plated palladium, fourteen centimetres long, slightly hollowed out on its upper surface and slightly curved backwards at its distal end, where it was notched to receive the central fold of the glosso-epiglottic ligament. The spatula was fixed at right angles to the handle and was provided with a small sliding plate at its proximal end, thus forming a short tunnel through which the light was transmitted and through which instruments could be passed. The handle was provided with a small electric lamp, the rays from which were directed along the spatula into the cavity of the larynx. The examiner, standing in front of the patient, who was seated in a chair with the head at an angle of sixty degrees with the trunk, introduced the spatula immediately in front of the epiglottis. The handle was then

Digitized by Google

elevated till the sliding plate came into contact with the teeth of the upper jaw; the epiglottis was thus raised and a view of the larynx and trachea obtained. Cocaine might be used with advantage, but there was considerable variation in the success of the procedure, many patients being unable to stand the necessary pressure. If successful a very good view of the larynx and trachea was obtained. Dr. Turner did not think that autoscopy could take the place of ordinary laryngoscopy, but it was very useful in children where an anæsthetic was used.

The PRESIDENT showed specimens of the Instruments used by native Indian Oculists for couching cataract, which had been sent by his friend Dr. Jennings. An ordinary bleeding lancet was used for the incision, and the lens shot out with one of the instruments shown which consisted of a bayonet-shaped blade made of coarse metal.

Dr. AITCHISON ROBERTSON read a paper on the *Rôle* of the Carbohydrates in Diabetes with an Inquiry into the Constitution of Infants' Food. Having glanced at the part played by the carbohydrates in diet he next considered the digestion of starch by the saliva and in pancreatic digestion. In infants the secretion of saliva was small and the diastatic ferment small in amount. Little starch could be digested. At the end of the first year diastatic property reached a maximum. The best food for infants was mothers' milk. Many children were fed on condensed milk, but he thought children fed thus were liable to gastro-intestinal troubles and convalesced from illness more slowly than those fed on mothers' milk. The sweetened variety of condensed milk was most used, but contained much added sugar. These milks were not to be recommended. He had examined specimens of various artificial foods after preparation according to the directions given and not as found commercially. He concluded that most consisted of wheaten flour mixed with malt. In many the preparation with boiling water prevented the conversion of the starch. Instead of malt some contained pancreatic ferment, but in the ordinary feeding of children it was not necessary to digest the proteid matter for proteid was well digested by children. In some of the foods the starch had been fully converted by the diastase of malt into dextrines. Combinations of starch and dextrine were present in some foods. If these dextrinised foods were properly prepared they formed a valuable addition to the milk with which they were used. Almost all the artificial foods were deficient in fat, so cream should be added in their preparation. — Dr. CARMICHAEL, Dr. BLACK, Dr. GILLESPIE, Dr. JAMIESON, Dr. BURN MURDOCH, and Dr. RITCHIE took part in the discussion which followed.

Dr. BYROM BRAMWELL read notes on a remarkable case of Primary Sarcoma of the Liver which simulated hepatic abscess. The patient, a young woman aged twenty-five years was admitted to the Royal Infirmary, Edinburgh, suffering from debility, emaciation, and pain in the right side of the chest. When admitted to the hospital dulness was found posteriorly with the typical curve of a pleural effusion. A hypodermic needle was inserted by the house physician, but no fluid was obtained. When the patient was examined while lying on her back it was at once noticed that the lower part of the chest on the right side was bulging and that the heart was displaced upwards. There was great pain in the fifth interspace in the right mammary line. A fluid enlargement of the liver was suspected. The needle of an aspirator was inserted at the painful point in the fifth interspace and some dark chocolate-coloured fluid was obtained. Hepatic abscess was diagnosed, although it was remarkable that the patient had never been out of the country, never had dysentery, nor could any cause for the abscess be discovered. Fifty-three ounces of dark chocolate-coloured fluid were drawn off with the aspirator. The fluid contained much more blood than would have been expected in an abscess. The microscope showed leucocytes, blood corpuscles, and debris of broken-down cells, but no characteristic cells could be found. She remained easier for some days, but the side became distended again and all her urgent symptoms returned. Mr. Cotterill operated and incised a large cavity and introduced a drainage-tube. She was much relieved, but blood continued to leak through the tube and produced profound anæmia. The tube was removed, ice bags applied, and various remedies tried, but the bleeding continued. Mr. Cotterill decided that the only procedure possible was to sew up the opening, which was accordingly done, and pressure applied. The bleeding stopped, but the cavity filled up again and had to be aspirated. The patient died a month after admission to the hospital, no other disease having been found in any other part of the body.—Dr. LEITH gave a description of the pathological conditions present. On cutting into the liver a large cavity was found occupying more than half the bulk of the organ. It contained broken-down blood-clot. Around were isolated centres of growth. The liver weighed about 9 lb. It was an example of the rare condition, primary sarcoma of the liver, consisting of spindle cells with some giant cells. The specimen and photographs were shown.—Dr. AFFLECK thought the case well illustrated the difficulties in diagnosing hepatic tumours. He remembered the case of a woman who was treated for typhoid fever for three months before being sent to the infirmary. On admission a swelling was found in the hepatic region. It was aspirated and some chocolate-coloured matter removed. The symptoms were so urgent that Mr. Duncan incised and found a large cavity containing grumous chocolate-coloured matter. The patient died and post mortem an abscess of the liver was found, which communicated with the stomach through a sinus leading to an old gastric ulcer.

Dr. JAMES RITCHIE read notes on two cases of Opium Poisoning. In the first case a catarrhal condition of the stomach was present, and when the stomach tube was passed seven hours after the laudanum had been taken a very considerable quantity was found in the stomach. The second case was treated with permanganate of potash, with very satisfactory results.

Reviews and Notices of Books.

Researches into the Anatomy and Pathology of the Eye. By E. TREACHER COLLINS, F.R.C.S. Eng., Assistant Surgeon to the Royal London Ophthalmic Hospital, Moorfields; and Hunterian Professor to the Royal College of Surgeons of England, 1893–94. With 10 Plates and 28 Figures in the Text. London: H. K. Lewis. 1896. Pp. 140. Price 6*s*.

THE volume before us, though of small compass, represents a very large amount of careful work. Mr. Treacher Collins held for several years the post of Curator of the Museum at the Royal London Ophthalmic Hospital, and had then as part of his duties to examine and report upon enucleated eyes, tumours, and pathological specimens generally. As the surgical staff of that hospital is large, the patients numerous, and operations frequent, he had extensive opportunities of observation, and of these he has taken advantage in a way highly creditable to his skill and industry, and has produced a work which, although by no means an exhaustive treatise on the pathology of the eye, yet treats of many subjects, and of each in so original and interesting a manner that the several chapters will be read and re-read by every ophthalmic surgeon, and will form the basis of the pathology of the eye in the text-books on the points with which he deals for some time to come. In the summer of 1894 Mr. Collins delivered a course of lectures as Hunterian Professor at the Royal College of Surgeons of England on the Development of Various Parts of the Eye, which he has reproduced here with much additional matter, consisting chiefly of the effects of concussion on the eye and the pathology of cysts of the iris.

In the first chapter he dwells at some length on the development of the suspensory ligament of the lens, showing that the fibres of which this ligament is composed are, in the first instance, cellular adhesions passing between the sides of the lens and the ciliary processes, and that as growth proceeds the cells lose their nuclei and become fibres. The absence of such fibres enables an explanation to be given of the condition known as coloboma lentis and ectopia lentis. He discusses the origin of true anterior polar cataract, a name he restricts to those opacities which are immediately posterior to the anterior capsule, and shows that they are formed by the proliferation of the cells lining the capsule, though after some time a hyaline layer is formed between the

Digitized by Google

proliferated cell mass and the lens substance, the anterior capsule in such cases appearing to split at its periphery of the neoplasm into two layers. He agrees with the late Mr. Hulke in thinking that another form of anterior polar cataract may result from perforating ulcer of the cornea and the temporary contact of the prominent surface of the lens with the flaccid cornea. The second chapter is chiefly occupied with the histology and pathology of zonular cataract and the etiological relation between this kind of cataract and rickets. He appears to think that the evidence at present obtained is in favour of the connexion of the two diseases. A short section is devoted to the development of the vitreous humour which he finds in a specimen from a fœtus believed to be about at the tenth week in the form of a thin layer separating the posterior surface of the lens from the inner layer of the secondary optic vesicle. A definite hyaline membrane is already present and the rudimentary vitreous is composed of a network of fine fibres with granules lying on them, the interspaces being filled with a clear fluid; he gives several drawings of sections of the central artery of the vitreous. The author devotes a chapter to Cysts of the Iris, a rather rare but very interesting form of disease. The first recorded case is that by Mackenzie, who noticed that the little tumour was preceded by a wound. In 1860 D. A. V. Guépin, in collating the various cases that had been reported up to that date, drew attention to the fact that cysts of the iris were generally, if not always, preceded by a punctured wound, and the correctness of his statement has received the support of all succeeding observers. The precise pathological conditions that lead to the formation of cysts of the iris are fully given by Mr. Collins. In some instances eyelashes have been translated by the instrument inflicting the wound into the substance of the iris, and the conclusion was drawn that the cysts in such cases proceed from the rootsheath; but in 1869 Mr. Hulke, after collecting the details of nineteen cases, suggested that a part of the membrane of Descemet might in some instances have been torn off and applied to the surface of the iris. Mr. Collins, however, points out that "cysts of the iris which follow wounds of the eye are, as a rule, found to be lined by laminated epithelium, and it seems," he thinks, "more probable that it is the surface epithelium which is implanted and which forms the starting point of the cyst rather than the endothelium on Descemet's membrane." This view is in accordance with the experiments of Masse, who produced both epithelial, pearl-like tumours and true cysts by grafting on the iris of rabbits' eyes fragments of conjunctiva and skin, and it is fully borne out by the microscopical examinations which have been made by Mr. Treacher Collins himself, of which he gives many original drawings.

In speaking of glioma of the retina Mr. Collins states that, although he has not made a special study of the retina, he has observed that the layers of the retina are quite undifferentiated in the human fœtus at the third month and that the retinal cells at that period are very similar in appearance to those which compose the mass of a glioma, the majority being rounded with large nuclei and some having minute spicules. He rightly observes that the differences between glioma and sarcoma are constant and well marked, glioma occurring in infancy or early childhood, affecting both eyes in 20 per cent. of the infants attacked and not recurring after removal if three years have elapsed; it is rarely associated with secondary growths, and arises from tissue of epiblastic origin, the cells being rounded with large nuclei and occasionally with spicules, whilst sarcoma may occur at any age, is never bilateral, is frequently followed by secondary growths, often presents fusiform as well as round cells, and arises from mesoblastic tissue.

In regard to the hyaline nodules which are to be met with in pathological specimens on the inner surface of the membrane of Bruch, Mr. Collins is inclined to believe that they are an excretion from the pigmented epithelial cells of the choroid, and attributes the formation of the membrane of Bruch itself to the same cells.

Referring to the difficulties that present themselves in explaining the occurrence of glaucoma, he proceeds to discuss the conditions which may lead to that affection in eyes in which the iris is partially or wholly absent; in those affected with buphthalmos, in cases occurring after cataract, in cases of traumatic aniridia, and in cases of recurrent glaucoma after iridectomy. He shows that in almost every case microscopical examination demonstrates that the glaucomatous symptoms arise from narrowing of the angle between the iris and cornea and consequent interference with the drainage of the aqueous humour. The drawings illustrating this are well executed. Mr. Collins may be congratulated both on the novelty and the value of his work.

The Histo-pathology of the Diseases of the Skin. By Dr. P. G. UNNA. Translated from the German by NORMAN WALKER, M.D. Edin. Edinburgh: William Clay. 1896. Price 31*s.* 6*d.* net.

THE publication of this work marks an important episode in dermatology. Nowhere but in Germany could an author have been found to undertake a work of such magnitude, 1205 large octavo pages, on the pathology of a single branch of medicine, and although Gustav Simon in 1848 (not 1840 as stated in the preface) undertook a similar task, both dermatology and histology were then in their infancy and the ground to be covered was therefore much less. Dr. Unna, indeed, does not now pretend to cover the whole ground of the histo-pathology of the skin. This would be far beyond the power of a single individual, who has aimed not at a compilation from the labours of others, but to go through *de novo* as much as he could by his individual efforts and those of his pupils working under his supervision. The work is divided into six sections: (1) Anomalies of Circulation; (2) Inflammation; (3) Progressive Disturbances of Nutrition, corresponding to what are usually classed as neoplasms, but including also pigmentations; (4) Regressive Disturbances of Nutrition, including Degenerative and Atrophic Changes, Gangrene, &c.; (5) Malformations; and (6) Saprophytes and Foreign Bodies—the saprophytes including a few vegetable parasitic diseases, and the foreign bodies being represented only by argyria. As might be expected, Sections 2 and 3 take up three-fourths of the entire book, 600 pages being occupied with the different forms of inflammation.

The author has very wisely prefixed a short clinical description of the affection he is about to consider pathologically. This enhances the value of the book to the general reader, and would be, indeed, necessary in many instances to the dermatologist, so that there should be no mistake about the eruption examined. It is the more essential in this work, as the author never hesitates to re-christen a disease, however generally recognised its original name may be, if he considers it may be more accurately described from a pathological standpoint. This is much to be regretted, for the multiplication of designations for the same disease by different authors has been the bane of dermatology in the past and has done much to hinder progress. No author can claim to be final in his views as to the pathology of any eruption, and as revision of pathological theories is constantly going on if every generation of pathologists should consider itself entitled to alter the names already in vogue because they express a possibly exploded theory of its pathogeny, it is obvious that there will be no finality. All old-established names are better left simply as labels, which may be quite distinctive even if they are not pathologically sound.

We do not intend to discuss the author's views of the individual diseases of which he treats. This would involve a general analysis and go far beyond the scope of a review

Digitized by Google

Everywhere he states the grounds on which he draws his conclusions and points out where he differs from previous authors, and he gives most of the recent bibliography at the end of each article. It remains for the reader to weigh for himself the facts with the conclusions and form his own opinion according to his judgment founded on clinical and pathological experience. Whatever the result in individual instances there can be no question that the author has done a profound service to dermatology and has not only laid a broad foundation but erected much of the superstructure which the now numerous band of young and enthusiastic workers can assist to complete.

The work should be read carefully by every dermatologist who wishes to keep abreast of his subject, and every practitioner who is interested in diseases of the skin will never regret having devoted some of his spare time to perusing the more general pathological portions of the work.

Much praise is due to the translator, Dr. Norman Walker, who has executed a difficult and arduous task in a very creditable manner. The work is done into very readable English, and it is only where there was no exact equivalent in English for some of the new pathological terms that it is observable that the work is not originally an English one. It has also some advantages over the German edition. Dr. Unna has seized the opportunity "to make certain alterations and emendations of the original," and at Dr. Norman Walker's suggestion illustrations have been freely introduced, so that there is a double plate of nineteen coloured figures prefixed and forty-two well-executed woodcuts in the text. The publisher's share in the production of the work leaves nothing to be desired, and author, translator, and publisher are to be congratulated on their enterprise in undertaking and success in producing such an important and valuable work.

The Pathology and Treatment of Venereal Diseases. By ROBERT W. TAYLOR, M.D., Clinical Professor of Venereal Diseases at the College of Physicians and Surgeons, New York. Pp. 1000. Edinburgh and London: Young J. Pentland. 1896.

THE first thing which strikes the reader of this bulky encyclopædic work on venereal diseases is the space allowed to gonorrhœa and its complications, immediate and remote, these alone taking up half the book, or rather more than is given to syphilis and its sequelæ. This well illustrates the change which has come over modern views with regard to these complaints. Gonorrhœa is no longer regarded lightly by the surgeon, as the serious character of sequelæ in women as well as men has been so prominently brought forward in recent years. The work, as we have mentioned above, is of an encyclopædic character. Dr. Taylor does not confine himself to his own experience and observation, but gives, often with tedious fulness, the views of others, even when they have been long exploded. If a second edition should be required the pruning-knife must be freely employed; moreover a separation of the work into two volumes would make it much more convenient. We hope also that some of the histories (often quoted from other authors), which are given in the book will be reconsidered before they are admitted into a future edition in their present form. The work begins with a consideration of gonorrhœa in the male. A description of the anatomy of the parts is followed by an admirably clear account of the gonococcus and its life history and a very judicial consideration of the importance to be attached to its presence or absence in stained specimens of the discharge. With reference to subacute and chronic cases the author says: "But the doubt comes in in subacute and chronic cases, just the ones in which we are anxious to determine whether the long-drawn-out inflammation is really kept up by the gonococcus, and whether this micro-organism has, as it is claimed it has, an indefinite life as a morbific agent in the male urethra. It will be very readily seen that the bacteriological studies of the urethral secretions are very difficult, intricate, and attended at every step with liability to doubt, confusion, and error; consequently scepticism and conservatism are warranted, indeed are essential, even in the presence of statements made by experienced and skilled observers." The morbid anatomy of chronic gonorrhœa and of stricture is clearly described and well illustrated, and the symptoms, complications, and treatment of gonorrhœa in the male are given in great detail. Gonorrhœal ophthalmia is also well described and the treatment very clearly indicated. The sequelæ, such as gonorrhœal rheumatism, general pyæmia, endocarditis, &c., are clearly described and references given to recently published papers. The late local effects, such as stricture, are very fully considered. Gonorrhœa in the female and the sequelæ of pelvic inflammation and suppuration receive the full attention that their recently recognised importance demands, and this section of the book concludes with an account of the conditions often met with as accompaniments of gonorrhœa, balanitis, phimosis, and paraphimosis, and there is also an excellent account of vulvo-vaginitis frequently met with in children, which Dr. Taylor agrees with most English observers in regarding as usually non-specific.

The section on Chancroids is adequate and the coloured plate accompanying it is excellent. Iodoform in America, as here, is the application chiefly relied on.

The section on Syphilis occupies the second half of the book, and so far as the account of the primary and secondary stages is concerned is excellent. The morbid anatomy and the various modes of infection are considered and a good account of the appearances of the chancre and its variations according to its site are given, the letterpress descriptions being here much superior to the coloured plate. The general symptoms—fever, albuminuria, and cutaneous affections of the secondary stage—are fully and clearly described, as are the secondary affections of the eye and ear. The treatment of syphilis in the primary and secondary stages is considered at great length. We are surprised to find Dr. Taylor emphatic in advising postponement of mercurial treatment after a chancre has been diagnosed until undoubted secondary symptoms occur. Nothing seems to be gained by this delay except, as Dr. Taylor suggests, that the alarm experienced by the patient will make him willing to undergo the prolonged course of treatment necessary. Dr. Taylor is a strong advocate of mercury. Although admitting the efficacy of inunction he seems to find it resented by patients, and administers mercury in the form of the green iodide or tannate in pill for six months, suspending it when there is trouble with the gums or bowels. Soon after this he adds to the mercury iodide of potassium, giving a mixture containing the perchloride of mercury and iodide of potassium throughout the secondary stage.

The consideration of tertiary syphilis and of congenital syphilis is meagre and unsatisfactory as compared with other parts of the subject. In another edition the book would be greatly improved by an amplification of these sections and compression of the chapters on treatment. The writer has given the views of others very fully, often only to discountenance them. The book would be more useful if antiquated methods were expunged and the results of the writer's own extended experience given more prominently. With these slight qualifications we are able to express nothing but admiration for the work.

The descriptions are clear, the illustrations for the most part accurate and helpful, and the fulness and detail with which the subject is treated make the book one of the most useful works of reference that the busy practitioner can keep on his shelves.

The Diseases of Children's Teeth: their Prevention and Treatment. A Manual for Medical Practitioners and Students. By R. DENISON PEDLEY, M.R.C.S., L.D.S. Eng., F.R.C.S. Edin., Dental Surgeon to the Evelina Hospital for Sick Children, Southwark. With numerous Illustrations. London: J. P. Segg and Co., Regent-street. America: The S. S. White Dental Manufacturing Company, Chestnut-street, Philadelphia, Pennsylvania, U.S.A. Price 7*s.* 6*d.* 1896.

THIS book is written by a dental surgeon who has had an unusual experience in the subject of which he treats and who is already known to the profession by his careful investigations into the condition of the teeth of children in our large pauper schools. It is designed for the use of general practitioners in medicine, who are not infrequently consulted about the teeth of children and are often so situated that they have to supply the place of a dentist. There is, perhaps, a tendency on the part of students to neglect the dental department of their hospital, and this book is well adapted to assist them in the requirements of active practice. The book is divided into eight chapters, which treat of the structure of teeth; eruption; caries; inflammation of the pulp; inflammation of the periodontal membrane, periodontitis, alveolar abscess, necrosis, and other sequelæ; irregularities of the teeth; hygiene of the mouth; and treatment. Whilst not too diffuse there is enough said on the various subjects treated of to enable the practitioner to gain a fair working knowledge of the subject, and the practical suggestions made regarding treatment should enable him to do much more than extract teeth for the relief of pain. The illustrations are numerous and adequate; in the chapter dealing with irregularities of the teeth they are even too numerous and take up too much space. There is a good index. Mr. Pedley may be congratulated on having written a useful book, and one which supplies a want in the profession.

Analytical Records
FROM
THE LANCET LABORATORY.

SCOTCH WHISKY, "BIG BEN" BRAND.
(JAMES S. DENMAN AND CO., 20, PICCADILLY, W.)

AN analysis of this sample gave the following results: alcohol, by weight 40·30 per cent., by volume 47·67 per cent., equal to 83·54 per cent. proof spirit; extractives, 0·16 per cent.; mineral matters, 0·02 per cent.; acidity, calculated as acetic acid, 0·03 per cent. The whisky is stated to be ten years old—a statement which seems to be borne out by the soft and mellow character of the spirit to the taste. The low amount of extractives and the practical absence of acidity are noteworthy points.

"ANTI-MICROBE" SPIRITS.
(LEROY'S ANTI-MICROBE AND WINE AND SPIRIT CO., LIMITED, MANCHESTER; AGENT IN LONDON—A. H. WACHTER, 38, CHEAPSIDE.)

The basis of these preparations, including brandy and whisky, is an elixir which is described as being prepared (we quote it strictly) "from a recipe found among the manuscripts of an old Egyptian *savant*, and with the help of the highest medical and scientific authorities ingredients have been added which make the elixir an infallible remedy and antidote in all miasmatic diseases." The elixir tastes and smells strongly of an oily aromatic product suspiciously like pumilio pine; it contained 1·63 per cent. solid matter and 0·10 per cent. mineral matter. On evaporation of the brandy the liquid as the alcohol was expelled turned milky from separation of oil. The fixed residue amounted to 2·02 per cent. and the mineral matter to *nil*. The brandy gave a strong black colour with perchloride of iron, indicating tannic acid extractives. Its alcoholic strength was 41·29 per cent. by weight, 49·81 per cent. by volume, equal to 87·29 per cent. proof spirit. There are two kinds made, one for hot climates and the other for ordinary use, the latter probably containing less elixir. From the malarial point of view we believe the preparations to be worthless, and it is a pity that the manuscripts referred to in the statement above survived the "Egyptian *savant*," and, still worse, that medical and scientific authorities were found—if that is a fact—to "help" in suggesting "ingredients" which "make the elixir an infallible remedy and antidote in all miasmatic diseases." We should have been inclined to have looked upon the so-called remedy with slightly more favour if the vehicles chosen for its administration had not been whisky and brandy.

HOME-MADE BEEF TEA.
(FREDK. MASON, YORK WORKS, 52, ACRE-LANE, BRIXTON, S.W.)

A really valuable "invalid" preparation of this kind should be contained in glass jars rather than tins, since in the latter case there is always a risk of metallic contamination, especially when, as in this instance, the contents are liquid. We obtained a distinct, though probably not serious, indication of metal in this preparation in confirmation of this view. Otherwise its composition is excellent, analysis showing it to contain the nourishing as well as stimulating constituents of beef in good proportion. The "tea" was in good condition and perfectly sound to the taste. Though according to the microscope it contained no muscular fibre, an albuminous precipitate derived from the decomposition of alkaline albuminate was obtained on boiling with a few drops of acetic acid. Analysis gave the following results: total dry matter, 10·44 per cent.; consisting of matters precipitated by alcohol, 7·06 per cent.; albumin, 0·60 per cent.; crystalline principles (creatin, &c.), 2·10 per cent.; and mineral matter, 0·68 per cent.

(1) ACID GLYCERINE OF PEPSIN; (2) IMPROVED GREGORY'S POWDER; AND (3) AURAL OVOIDS.
(J. G. BULLOCK AND CO., 3, HANOVER-STREET, HANOVER-SQUARE, W.)

Glycerine, as is well known, is an excellent vehicle for administering pepsin since it is a good solvent, and is, moreover, preservative. The preparation before us possesses high digestive power, as proved in our experiments with it on albumin, and it is practically free from the objectionable taste which frequently characterises digestive mixtures with the same basis. The chief merit of the improved Gregory's powder consists in the purity of its ingredients and consequent freedom from inert matters. It may conveniently be taken in "rice" capsules. "Aural ovoids" are intended for the application of certain medicaments in the ear passage. We have examined the following: (1) extract. opii, ½ gr.; (2) extract. opii, ½ gr., cocaine hyd., $\frac{1}{16}$ gr.; and (3) iodoformin 1 oz., extract. opii, ½ gr.; but ovoids containing other substances may be had to order. Their use and value are emphasised in the translation of Professor Grüber's "Diseases of the Ear" by Dr. Law and Dr. Jewell.

JEYES' SANITARY COMPOUNDS COMPANY, LIMITED, have received three further awards for their preparations—viz., Second Leicestershire Trades and Industrial Exhibition, held at Leicester, a gold medal; Yorkshire Brewers and Allied Trades Exhibition, held at Leeds, a gold medal and diploma; and Second Derbyshire Trades and Industrial Exhibition, held at Derby, a gold medal and diploma. The same firm have been again entrusted with the disinfection of Bisley Camp during the meeting of the National Rifle Association.

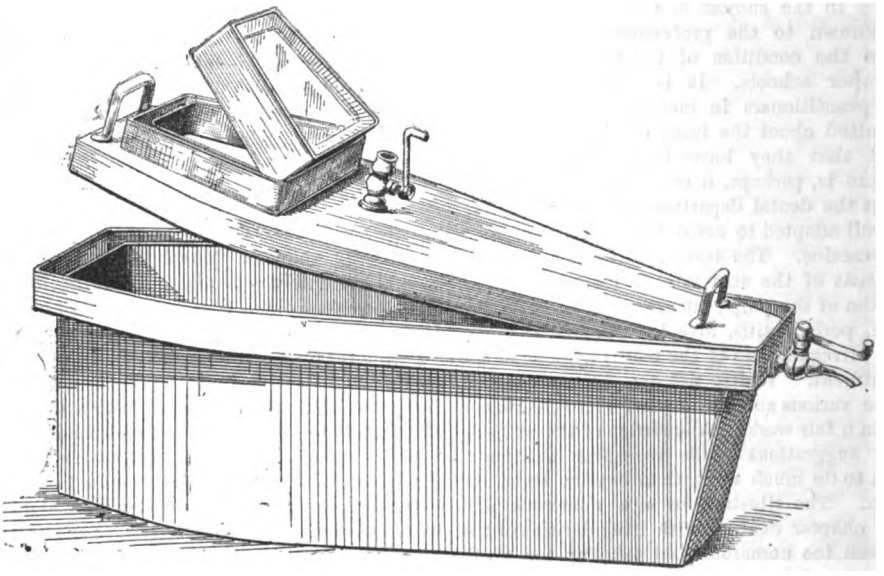
New Inventions.

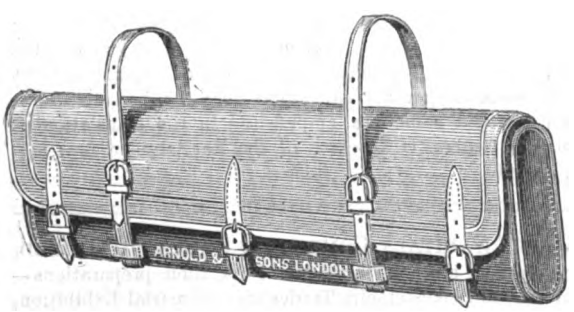
BIRCH'S MORTUARY SHELL.

THE mortuary shell illustrated below is one which may be worthy of the attention of public bodies, hospitals, vestries, shipping authorities, &c. From the illustration, which explains the invention as well as any written words could do, it will be seen that the corpse can be viewed through the glass face-piece without any fear of infection, and by filling a gutter running round the line of junction between the lid and the main receptacle with water the shell can be hermetically sealed. Lastly, a small tap in the centre of the lid, which communicates with the interior of the shell, can have attached to it indiarubber tubing leading out of the window or up the chimney, thereby preventing accumulation of gas. The weight of the shell is about three-quarters of a hundredweight, and the cost (according to size) is as follows: 5 ft. 6 in. long, £6 5s. net; 6 ft. long, £6 10s. net; 6 ft. 6 in. long, £7 net. The shell is manufactured at Myerson's Iron Works, 211 and 213, St. John-street, Clerkenwell, and a specimen may be seen at the St. Marylebone mortuary.



A MIDWIFERY SATCHEL FOR THE SADDLE.

PERHAPS a description of a leather case for midwifery instruments and bottles, which Messrs. Arnold and Sons, London, have made for me, will be of use to some country practitioners who do most of their work on horseback. The case is made of the best cow-hide and is fifteen inches long by eleven inches in circumference; it is oval at the ends and is closed by three straps and attached to the front of the off-side of the saddle by two encircling bands of leather. Its



contents are as follows. One three-ounce bottle for chloroform; two one-ounce bottles for ergot and chloral; hypodermic syringe in case, with tabloids of ergotin and morphia; a pair of frænum scissors; packet of curved needles with stout silk sutures; a vaginal syringe; silk catheter, No. 8; and a pair of Simpson's long forceps. All the instruments and bottles fit in perfectly and can be taken out for use as quickly as from the ordinary obstetric bag. The satchel is not in the way when riding.

GEORGE D. MACKINTOSH, L.R.C.P. Irel.

A NEW OPTOMETER.

WE have received an optometer from Mr. Davidson, of 120, Great Portland-street, London, W., adapted to facilitate the selection of appropriate glasses in cases of myopia, hypermetropia, and astigmatism. It consists of a stand supporting a transverse bar, along which travel two wooden discs about ten inches in diameter. In the rims of these discs are inserted fifteen lenses, viz., −1 D, −2 D, &c., up to −8 D, and + 1 D, + 2 D, &c., up to + 7 D., and more might, perhaps, with advantage have been added. A blackened disc with a stenopæic slit can be placed before each lens. An arm, easily removable, at right angles to the transverse bar, and on the same plane, supports a frame in which a card slips having variously sized type and an astigmatic clock. This arm is perforated and can be attached to a gas pipe so that good illumination is secured. A small rack is attached to the stem containing a few extra glasses such as a 0·25 D, a prism, and several other glasses. The instrument is handy enough, and can be applied in addition to its use as a test for refraction as a means of determining the defect, if any, of convergent power, and by means of appropriate dials and cards of colour-blindness. It will prove useful to the country practitioner, and the cost, four and a half guineas, is moderate.

THE LANCET.

LONDON: SATURDAY, JUNE 20, 1896.

THERE never was a time in the history of the Royal College of Surgeons of England since 1843 when it was more desirable that the reforming element in the Council should be strengthened. At successive elections in late years Fellows anxious to advance with the times and to satisfy the legitimate aspirations of the Fellows and Members have been elected to the Council by very substantial and sometimes triumphant votes. The result of this has been that opinion on the Council is now very evenly balanced and the addition of one or two reforming Fellows would completely turn the scale. We have lately commented on the peculiar vicissitudes in the prospects of the Members of the College obtaining representation on the Council due to the chance presence or absence of reforming Fellows. At one moment everything seemed favourable for the immediate settlement of the question, and the next, owing to determined opposition at an opportune moment, reform kicked the beam. These vicissitudes do not enhance the dignity of the Council or conduce to the welfare of the College, and as they retard the development of the College as one of the greatest professional institutions in the United Kingdom we should be glad—loyal as THE LANCET has ever been to the cause of reform—to see a decided accession of strength to the more liberal section of the Council. The present time, moreover, is peculiarly favourable for the settlement of all constitutional questions which have arisen both as regards the privileges of the Fellows and the representation of the Members of the College upon the Council. The latter question dominates the situation entirely. If the Fellows of the College when polled should be so ill-advised as to vote largely against the Members' claims, a contingency, however, which we are far from expecting, all changes favourable to the Fellows will have to wait; but should there be a large or substantial majority the other way the Fellows will be able to secure what privileges they please. This is a consequence which the Fellows should not lose sight of at the coming election. The difficulty, however, arises that there will only be one absolute vacancy—namely, that created by the retirement of a gentleman who had decidedly liberal tendencies, and voted for the polling of the Fellows which is now about to take place, whilst those who are standing for re-election are opposed, no doubt conscientiously, to the Members' request for representation, as shown by their recent votes, and yet they have certain claims upon the constituency for re-election which we do not wish to ignore. It certainly seems strange to us, nearing as we are the close of the nineteenth century, during which so much has been done to remove disabilities and popularise institutions, that there should be found in the Council of the College nearly a dozen Fellows who feel keenly that the admission of representatives of the Members of the College, and especially Members themselves, to the Council Board would be a very dangerous and lowering measure. And yet so it is, and we deplore it, and deplore it more especially because among these Fellows are some of the most useful and active Members of the Council—men who occupy leading positions as surgeons, lecturers, teachers, and authors. This is the situation, and we feel it our duty to state it without desiring to influence the votes of the electors one way or the other. No doubt obstacles of this kind will gradually disappear, and disappear very quickly if the Fellows will unmistakably indicate by their votes, in answer to the Council's circular, that they wish the Members to share in the privilege of electing the Council. This would supply a remedy at once, and we appeal to the Fellows at large to end in this special manner a condition of things which really paralyses the energies of the Council, inasmuch as it perpetuates interminable discussions both inside and outside the Council concerning a concession to the Members which will abstract nothing from the power and influence of the Fellows in the Council of the College. With regard to the candidates themselves, the electors cannot complain that their choice of fit and proper persons to represent them is limited or that there is any want of variety in the qualifications of these candidates. On the contrary, in recent years there has been *un embarras des richesses*, and owing to the severe competition and the conflicting claims upon the votes of the electors several candidates who would have made most excellent councillors have not only failed, perhaps on more than one occasion, to command success, but have retired disheartened from the field. This year there are eight candidates for three vacancies created by the retirement in rotation of Mr. CADGE, Mr. BRYANT, and Mr. PICK. Mr. CADGE, having enjoyed two full and consecutive terms of office amounting to sixteen years, has retired from the Council altogether, while Mr. BRYANT (Fellow, 1853), who has served for the same period, and has been re-elected for five years as the representative of the College in the General Medical Council, and Mr. PICK (Fellow, 1866), who is now one of the vice-presidents and has served for eight years only, are standing for re-election. The six other candidates in the order of seniority are Mr. GEORGE POLLOCK (Fellow, 1846), Mr. J. N. C. DAVIES-COLLEY (Fellow, 1870), Sir W. B. DALBY (Fellow, 1870), Mr. R. CLEMENT LUCAS (Fellow, 1871), Mr. EDMUND OWEN (Fellow, 1872), and Mr. W. J. WALSHAM (Fellow, 1875). Of the eight candidates three are connected with St. George's Hospital, three with Guy's Hospital, one with St. Mary's Hospital, and one with St. Bartholomew's Hospital.

It is never a very congenial task to us to make a choice of particular candidates for recommendation to the suffrages of the electors, and the task is not always an easy one because of the reticence of candidates themselves in regard to their views on current questions. Of the eight candidates for the Council we know the views of four or five more or less completely, three being more or less reformers and the other two upholders of the *status quo ante*. The three former are Mr. GEORGE D. POLLOCK, Mr. DAVIES-COLLEY, and Mr. CLEMENT LUCAS. Mr. POLLOCK might of course have been elected to the Council long ago, and no doubt have held the office of President, had he cared to come forward for the Council

Digitized by Google

when he was well known to the Fellows generally, but, curiously enough, he could never be persuaded to do so by his numerous friends and admirers. A more high-minded and honourable gentleman and accomplished surgeon does not exist in the profession, and his candidature has been prompted by public spirit at a time when he is fully entitled to enjoy the *otium cum dignitate*. He is sincerely desirous to see the Council of the College acting in perfect harmony with the Fellows and with the Members of the College, and he is fully convinced that it is time that the Members of the College received due recognition of their claims to representation. The great advantage of his accession to the Council would be that the electors could absolutely rely on his conforming in the Council to the views and policy which he has for many years supported as President of the Association of Fellows, which must be greatly indebted to him for his faithfulness to the cause of reform even in periods of discouragement, and which ought to be loyal to him to a man. Of Mr. DAVIES-COLLEY we have spoken favourably on previous occasions, and we believe that he has liberal tendencies, but we are not so fully assured of his zeal as of that of his junior colleague, Mr. CLEMENT LUCAS, who has expressed his intention of advancing the cause of progress and supporting the Members' claims. Of the views of Sir WILLIAM DALBY, Mr. EDMUND OWEN, and Mr. W. J. WALSHAM we really know little or nothing. We know that Mr. OWEN is a popular surgeon, with considerable force of character, and if he be at all imbued with reforming principles we may be sure that he will express them forcibly and act on them energetically. We sincerely trust that Mr. WALSHAM'S reason for coming forward is not because he thinks that St. Bartholomew's Hospital is insufficiently represented in having only five members of its staff on a council numbering twenty-four Fellows. Possibly he may be urged by an irresistible *vis a tergo* and has not fully considered the subject, but we really think that the staff of St. Bartholomew's Hospital should adopt a self-denying ordinance and decide not to put forward another colleague as a candidate for the Council until one at least of the present group on the Council retires. St. Bartholomew's Hospital has supplied so many Fellows to the College that if their full strength is polled they can probably carry their representative into the Council, especially where the candidates are numerous; and St. Bartholomew's Hospital is so strong that it ought to be merciful and spare a seat for some unrepresented school.

This, then, is the position of affairs, and the task imposed upon us will be seen to be one of great difficulty and delicacy. With regard to the re-election of Mr. BRYANT we are opposed on principle to the re-election of a councillor for a third eight years' term of office, especially when he has enjoyed most of the honours and emoluments which the College has to offer, including the Presidency. Moreover, we are not in accord with Mr. BRYANT on the question of the representation of Members of the College on the Council, of which he is, perhaps, the most determined opponent. On the other hand, Mr. BRYANT is a representative surgeon and a regular and active member of Council and the representative of the College on the General Council of Medical Education and Registration, and although it is not necessary for this representative to be on the Council, the late Mr. MARSHALL having held the office after he left the Council, it is certainly more convenient. Mr. PICK has fair prospects of becoming President in due course, and has many excellent qualities as a surgeon and member of Council, but, again, we are not in accordance with his views on College politics. On these topics we could not desire better representatives than either Mr. POLLOCK or Mr. CLEMENT LUCAS, our only regret being that Mr. POLLOCK has deferred his candidature so long, for he is senior even to Mr. BRYANT as a Fellow of the College. We have no doubt that any one of the other candidates would prove a good Councillor, but we are not so certain about their views and we cannot recommend a sixth representative of St. Bartholomew's Hospital. In the foregoing remarks we have endeavoured to place the position of affairs impartially before the Fellows, sincerely trusting that they will arrive at a decision which will be just to individuals and at the same time conducive to the welfare, progress, and development of the College.

THE case of REGINA *v.* PRIESTLEY is one possessing more than transient interest for medical men. PRIESTLEY, a person without any legal qualification as a surgeon or dentist and calling himself a herbalist and dentist, undertook to treat a female domestic servant and to remove certain teeth which he pronounced to be decayed. On April 17th the girl went to PRIESTLEY'S house at Idle and was there examined by him. She asked him if he gave gas and he appeared to have implied that he did, and further, when pressed by the girl's mistress as to whether the gas would do her any harm, he said that it would not. After taking a heavy meal the girl repaired again to PRIESTLEY'S rooms. According to the evidence he then gave her half an ounce of chloroform while she was seated upright in a chair and without loosening her clothing. No third person was in the room at the time of the administration. After a few minutes the unfortunate girl died from the effects of the chloroform. PRIESTLEY was committed by the coroner at the finding of his court for manslaughter and was tried under this charge at the Leeds assizes. In summing up, Mr. Justice WRIGHT said: "The law allows an unqualified person to perform operations and practise his profession, and provided he is not negligent, but uses due care, he is not criminally liable," and as the jury were not able to agree that PRIESTLEY had shown negligence he was acquitted. That such is the law and the interpretation the forensic mind puts upon it cannot be gainsaid, but none the less is it a most deplorable state of affairs. While upon the one hand we have a number of special laws compelling medical practitioners to go through an expensive and arduous curriculum before "qualifying," yet upon the other hand we are told that the law so stands that any unqualified person may "practise his profession," even to the extent of giving a substance which leads to the patient's death, without let or hindrance. To give chloroform in the way in which PRIESTLEY is reported in the evidence to have administered it is to court disaster. It is discouraging to find that after nearly fifty years of its use so little general knowledge

Digitized by Google

of the properties of chloroform should exist and that the alphabet of its use should be unknown. If any medical man were to chloroform a patient sitting in a chair and with a stomach full of food he would be justly censured and would be certainly responsible for the results of his action. It then becomes a question as to who should give anæsthetics? Are these bodies such innocuous agents that the "man in the street" may use them with impunity? It was but a short time ago that a provincial surgeon informed our readers that he entrusted his patients' lives to a trained nurse, she administering the anæsthetic while he operated. In other hospitals we are told that the matron or a ward nurse acts as anæsthetist; the dispenser is also called upon to perform a similar office. It is a frequent occurrence in obstetric practice to intrust the chloroform to a nurse or even to one of those females who as *amicæ curiæ* hover about the parturient couch. It is, we learn, a common custom of dentists, whose qualification to practise is registration before July, 1878, or the possession of the L.D.S., to administer chloroform to their patients. There are several aspects of this most hazardous proceeding. When a medical man relegates to an unqualified person the duties which belong to him—and all, we presume, will admit that it is at least desirable that the chloroformist should possess such knowledge as would give the patient the minimum of risk whilst inhaling the anæsthetic—he becomes guilty of the offence of "covering." In the event of a patient dying from the effects of chloroform under these circumstances it is more than probable that an action for damages would be brought against the medical man who abetted the person giving the chloroform. But there is a higher platform and one from which the profession is always apt to view ethico-legal questions—that is the moral duty which we all owe to our patients to protect them from all possible risks and dangers. A glance through the records of fatalities enumerated in our recently published volume[1] reveals that even in the hands of expert and highly accomplished surgeons deaths under anæsthetics are constantly occurring. If such is the case what action can be more culpable than to increase the known peril of any operation, whether in obstetric or general surgery, by committing the chloroform into the hands of a nurse or other ignorant person? In the case of REGINA *v.* PRIESTLEY the defendant was given, by the judge's direction, the benefit of the doubt, but it is more than likely that others will be less fortunate and will learn when too late that a little knowledge is a dangerous thing alike to practitioner and to patient.

THE Army Medical Service has been drifting for some years past into a more and more unsatisfactory state, until it has reached a condition in which it fails to attract a sufficient number of candidates to fill its appointments. Lord ROBERTS the other day, in replying for the Army at the festival dinner in aid of the re-endowment fund of Guy's Hospital at the Imperial Institute, dwelt upon the great importance of securing the best men that could be got as officers for the Army Medical Staff, and he assigned several weighty, if obvious and commonly recognised, reasons in favour of that view. Almost every family in the United Kingdom, no matter in what station of life, is interested in the subject. In civil practice the advice and assistance of the highest authorities and of experts in any branch of the profession can be obtained in cases of unusual difficulty or gravity; but this obviously cannot be the case in army life. The military surgeon must very often rely entirely upon his own skill and judgment without any extraneous aid from men of acknowledged eminence and without, at any rate, the moral support of their opinion and experience. The army surgeon serving abroad is frequently in sole charge of an isolated district and of a large number of individuals quite beyond the reach of further aid, while to confine his labours within the strict field of his professional duties, pure and simple, would, in the opinion of the Government and military authorities, be attended with a waste of energy and an expense that would be prohibitory and impracticable.

It devolves upon a medical officer, then, to discharge other than strictly professional duties, notwithstanding that these are, and must always form, his primary and paramount duty—that for which he has been specially educated and is paid. Those, however, who know anything of army life are aware that these duties, except under special circumstances and conditions that are rather occasional than usual and ordinary, do not engross his sole attention, and that he has numerous other responsibilities and a large amount of work to discharge in connexion with extra-professional labours which the State has committed to his charge. As far as we can understand, the medical officers contend for one of two things—either for a purely professional department organised and paid as civil surgeons and physicians would be; or for a military organisation in which the medical department would be a military service discharging duties of a mixed and not a purely professional character. As they already hold the latter, then a position in the army worthy in every respect of its responsibilities and claims should be theirs. It must be "up to date" also, in the phraseology of the day, by which we mean that the position which the profession occupies scientifically and socially at the present time must be recognised, and this is not what it was fifty years ago. Medical officers contend that it was by no action of theirs that the relative rank which contented them in the past was abrogated, that it is not their doing that military rank and titles have been scattered broadcast among branches of the service that not so very long ago did not possess them, and that the possession of these alone should be held in respect or find favour in military eyes. We are strongly of opinion that the whole question, together with all other grievances—real and alleged, should be once for all carefully and impartially considered, and that the medical service should be justly and generously dealt with in a way calculated to satisfy all reasonable men in and out of the medical service.

If anyone will turn to the pages of THE LANCET during the past quarter of a century it will be found that we initiated, we may say, and have always advocated, the idea of the formation of an Army Medical Service under some such designation as a Royal Corps of Surgeons or Royal Medical Staff Corps, and that its officers should have power and

[1] THE LANCET and the Hyderabad Commissions on Chloroform.

Digitized by Google

command, but only, of course, within the limits of their functions. We are extremely sorry that this line was not followed years ago, as it would, we believe, have prevented all that has subsequently taken place. It is quite clear that the rank and position of every medical officer must be an assured and fully recognised one in the service, even apart altogether from the question of titles. There are, moreover, several very real grievances of which medical officers complain. Their life is one of comparative expatriation owing to the shortness of their service at home; and the frequent changes of station and duty to which they are subjected surely cannot be for the good of the service generally or of the patients committed to their charge. The rates of pay in India require to be readjusted; a medical officer should be paid wherever he is serving according to his rank. It would be a very good plan, in our opinion, to institute for the medical service something like that which the Staff College is for the general service, so that an incentive and impetus might be given to the more scientific and highly trained medical officers to make manifest their qualifications and attainments, and for this purpose, too, there should be greater opportunities afforded to them than exist at present for the *bonâ-fide* study of their profession. A service, again, organised on the dead level system of strict seniority does not, we confess, commend itself to us. Seniority is an important factor in weighing the claims of a medical officer for selection for the higher appointments, but seniority should not be the sole and dominating factor in such cases. There may be, and no doubt are, other points that could have been advantageously touched upon, but we trust that something has been done here to formulate the requirements of the service, and we can only hope that the War Office will give the whole subject full, fair, and impartial consideration.

Annotations.

"Ne quid nimis."

THE CAUSES OF DEATH IN COLLIERY EXPLOSIONS.

AN exceedingly important and interesting contribution to this subject has recently been published by Dr. Haldane in a Blue-book prepared for the Secretary of State for the Home Department. The report is based in the main upon the terrible explosions that happened in the Tylorstown, Brancepeth, and Micklefield explosions. We could wish we were able to publish this report *in extenso*, but its length precludes this course in spite of the excessive importance of the subject. Without entering into the specific details of each explosion, we may be content with simply recording the general results. Dr. Haldane divides the bodies of the unfortunate victims into two classes: first, those of men who had been killed by after-damp; and, secondly, those killed instantaneously by violence. It is the former class—which comprises 91 per cent. of the whole in the explosions referred to—with which we are more concerned in connexion with the consideration of affording some means of preventing this loss of life. There is little doubt that the cause of death by inhaling after-damp is due to carbon monoxide. This is clear from the investigation in some cases of the blood of the victims and from the characteristic, almost life-like, appearance of the corpses. The blood taken from both men and horses was shown by means of the well-known spectroscopic appearance afforded by carboxy-hæmoglobin to be highly charged with carbon monoxide. These facts make it evident that in most fire-damp explosions there must be in parts of the field of explosion not sufficient oxygen for complete combustion, and instead of carbon dioxide and aqueous vapour a variable mixture of carbon dioxide, carbon monoxide, watery vapour, and probably hydrogen will be formed, and these, when mixed with about 80 per cent. of nitrogen and any undecomposed fire-damp will constitute the after-damp. There are reasons for believing, however, that this proportion is by no means high, and it is probable on theoretical grounds that in an explosion with an excess of fire-damp and without dust not more than about 3 or 4 per cent. of carbon monoxide will be formed in any part of the track of the explosion. The evidence is clear, however, that whatever poisonous gases exist the gas present in the most poisonous proportions is carbon monoxide, and this gas undoubtedly occurs in the after-damp of all great colliery explosions. *A priori*, in these explosions there must have been an insufficiency of oxygen for complete combustion. Everything indicates in fact that the exceeding danger of after-damp is referable to the constant presence of carbon monoxide. Apart from the results of the experiments made with the blood, the pinkness of the lips and the general life-like appearance of the bodies recovered after explosions point to the same poison. From experiments tried upon himself, Dr. Haldane calculated that about six hours are required for the carbon monoxide to disappear entirely from the blood in severe cases of poisoning. Although this is so, the distressing after-effects continue, which may end fatally. In regard to treatment, Dr. Haldane considers the administration of oxygen would be of service in rapidly clearing the blood of carbon monoxide, but the first effect of cool fresh air would appear to be dangerous. This is suggested as being due to the cold diminishing the blood-supply to the brain or to the temperature of the body being reduced owing to impairment of the heat-producing or heat-regulating functions. At any rate the application of hot water bottles and blankets appear to be of great service. In regard to preventive measures, in addition to increased facilities for ventilating the mines in times of emergency, Dr. Haldane suggests that the work of rescue would be much more safe if a few simple precautions were observed. Thus the presence of a dangerous proportion of carbon monoxide may be detected easily and sufficiently quickly by observing the symptoms exhibited by a mouse. A few white mice might easily be kept for this purpose in the engine-room at the top of the down cast-shaft and be taken down in small cages by the rescuers. With the help of the indications afforded by the mice it would be possible for the rescuers to keep within the limits of safety and yet go forward with rapidity and confidence as far as they could. He also lays down some sensible directions as to the position the men should take after the occurrence of the explosion, and some reasonable measures which should be observed by the rescuing party. He suggests also that cylinders of compressed oxygen should be at all times available in the mine. As will be seen from this brief digest, the report is an admirable piece of work dealing exhaustively with the scientific aspects of colliery explosions, their probable nature, and the effects they produce. The community at large will welcome such an earnest and solid endeavour to minimise the sorrow occurring from one of the most distressing calamities that can happen in this country.

LORD KELVIN.

THE congratulations which fell so thickly and so unstintedly upon Lord Kelvin on the occasion of the commemoration of the jubilee of his professorship of natural

Digitized by Google

philosophy in Glasgow University represent something more, we are sure, than mere felicitation on so long a tenure of so distinguished an office. It was a fitting opportunity of recognising his brilliant achievements in scientific work and the splendid results of the application of his discoveries towards advancing so much of the progress in the public weal which has been so marked a characteristic of the closing century. As is well known, Lord Kelvin's keen perceptive faculty has been chiefly directed to the study of the laws governing that still mystical force—electricity. Yet with characteristic modesty he admitted the other day that he knew no more of electric and magnetic force, or of the relation between ether, electricity, and ponderable matter, or of chemical affinity, than he knew and tried to teach his students of natural philosophy fifty years ago in his first session as professor. He forgot to add, perhaps, in the exceeding good taste which he has always evinced, the enormous impetus, as the outcome of his work, which he has given to what we may call telegraphic science or the science of the transmission of words from distant lands and across the sea in a space of time so lightning-like as to excite our deepest wonder and admiration. His scientific triumphs in this direction were appropriately enough demonstrated in a very happy way on the occasion of the meeting at Glasgow to which we have referred. Thus a congratulatory message was sent from the jubilee committee by way of Newfoundland, Chicago, San Francisco, Los Angelos, New Orleans, Jacksonville, Florida, Washington, New York, Newfoundland, and thence to Glasgow University, a distance of some 20,000 miles, in about seven minutes. There was used for the first time a cable recorder on a cable and land wire of immense length. The marvellously quick time of transmission demonstrated the successful working of Lord Kelvin's syphon recorder. Despite his confession also as to his insight in regard to the vagaries of magnetic force he has so far mastered them as to have ultimately placed a marvellously accurate and delicate instrument at the service of the navigator, and we venture to say that there is hardly a ship afloat which does not carry a Sir William Thomson's compass, the boon conferred by the introduction of which will be admitted by all those who "go down to the sea in ships." Then there are the manifold instruments of exact measurement used in physical science which are less prominent as directly of public service, but none the less are they of equal importance, and a reference to text-books on physics will reveal how intimately associated with Lord Kelvin's name is almost every section of electrical and magnetic science. The medical profession upon whose labours Lord Kelvin's discoveries are not without an important bearing will join, we feel sure, in adding congratulations to those already awarded him and to which he is so richly entitled.

"A BENEFICENT MEDICAL DISCOVERY."

UNDER this somewhat high-faluting title a contemporary makes a good deal of copy anent the use of oxygen with chloroform. An interviewer waited upon Mr. T. G. H. Nicholson, M.R.C.S. Eng., anæsthetist to the Hahnemann Hospital, Liverpool, and naturally found that gentleman "shy." Unfortunately he appears to have overcome his shyness and to have dropped that laudable reticence which, we are told, cloaked his speech when first approached. Had he at once stated to the representative of the *Liverpool Courier* that he possessed no right to be regarded as a discoverer he might have avoided both undesirable notoriety and newspaper puffing which should be a source of extreme annoyance to any member of the medical profession. We are told that this gentleman patented an apparatus for administering oxygen gas with chloroform in 1893, but the idea had been "simmering" in his head since 1891. We do not suppose for one moment that any wilful misrepresentation of facts has been intended, but it is of interest to trace the "simmering" of the same idea in other minds throughout the past twenty years or so. The "discovery" is the well-known method of Neudörfer, which he introduced into practice in Vienna about twenty years ago. Even as early as 1860 Lallemand, Perrin, and Duroy investigated the supposed antidotal value of oxygen in chloroform toxæmia, and came to the conclusion that its merits in that respect were slight. Snow in 1849 was also familiar with it and recorded a case in which forced respiration of oxygen was practised in what proved to be fatal syncope. Neudörfer, however, suggested that by actually combining oxygen gas with chloroform vapour it might be possible to lessen the risk of asphyxia. Whether this was done by maintaining the vitality of the tissues or by simply producing a due dilution of the chloroform does not appear certain. At all events, Idelson, Bertels, Kreutzmann, and others have followed Neudörfer's method and have regarded it with favour. Mr. George Foy described a simple apparatus for giving oxygen, and this can be combined with a chloroform apparatus, affording a ready means of combining the use of oxygen and chloroform. Kreutzmann[1] also devised an apparatus of less complexity than that which Neudörfer employed. The mixture has further been successfully tried in America, but experience has taught that while oxygen is of value in asphyxial conditions it really possesses no merit as a physiological antagonist to chloroform. The plan referred to is neither new nor yet so old as to be safely re-introduced as a novelty, save in the pages of a lay journal whose zeal for "copy" outruns its discretion. Many letters of somewhat fulsome adulation of this "discovery" have appeared, but as yet we have not seen any disclaimer from Mr. Nicholson of this bantling or any attempt to render to Neudörfer whatever credit may be due for his discovery.

TOXICOLOGICAL EFFECTS OF CREOLIN.

CREOLIN compounds are now so extensively used as disinfectant washes, more especially as they are believed to be non-poisonous, that the results of an investigation by Professor Hobday of the Royal Veterinary College calculated to disturb this notion will be read with interest and instruction; at any rate, they should place the public on their guard in respect to the application of these compounds to the body. The investigation was set on foot by observing the fatal effect of applying solutions of creolin to a couple of valuable ferrets affected with lice and mange. The amount of creolin used was estimated at about two ounces to a quart of water, in spite of which dilution both animals were dead within half an hour of the application. Again, in the case of a valuable bull terrier severely affected with follicular mange "the result was most alarming and all attempts to save the animal failed," the application having consisted in rubbing the affected parts with a solution containing four ounces of creolin and four ounces of water. To set at rest the question whether this alarming result was due to any peculiar idiosyncrasy of the animal a fox terrier was treated in the same way, but the result was equally unfortunate. Several animals (dogs and cats) were then submitted to experiment with more or less toxic effects, and in the majority of instances those effects were followed by death. This important report concludes with the following observations: that creolin is a narcotic and irritant poison to the dog and cat, and that its use in these animals must be watched with the greatest care; that it is especially toxic when spread in emulsions of a certain strength over a large area of the body; that

[1] Centralblatt für Chirurgie, No. 35, 1887.

Digitized by Google

its effect is more rapidly seen and more violent when mixed with water than when applied pure or when mixed up into the form of an ointment; that when mixed in certain proportions and applied externally it will act as a violent irritant; that the less refined preparation of creolin is not so toxic in action as pure creolin; and that it is not so readily absorbed from the stomach, from small wounds, or from the subcutaneous tissues as from a large area of skin surface. The results are certainly very striking and would appear to show that creolin cannot be regarded as an absolutely safe external application. Its claimed advantage, therefore, over carbolic acid of being non-poisonous cannot fully obtain. Professor Hobday does not enter into the exact composition of the preparations he used. It may be fairly assumed, however, that they consisted of a strongly alkaline and resinous solution of cresylic acid. Did the alkali play any part in the symptoms observed, and was carbolic acid present in appreciable quantity? The observations, at any rate, are valuable and are based upon trials made with preparations to be found on the market which are generally stated to be innocuous. It is reasonable from the foregoing to enjoin care in the use of these preparations for external application to the human being and other animals.

THE POSITION AND REMUNERATION OF MEDICAL MEN.

OUR correspondent "M.D." discusses many subjects any one of which would require a leading article for its proper treatment; the amendments of the Medical Act; the exposure of qualified men to the competition of charlatans; the overcrowding of the profession, caused partly by the competition of the schools and of the examining boards; the absence of instruction in the business aspects of the profession; the alleged want of consideration of medical teachers for the ultimate fate of students; and the want of provision in our medical societies for discussion of matters of professional reform and political combination, are all touched on in his suggestive communication. We shall not attempt to treat these subjects in one short article. The state of the profession might well occupy our leading corporations and societies a little more than it does. There is certainly one reform that might be further pressed without hardship to any and with infinite advantage to the public—we mean the exaction from *entrants* to the profession of proof of a more complete preliminary education than is now required. This would check the rush into the profession at a merciful point, and before men who were never meant for such a pursuit had committed themselves to it. As to the necessity for amendment of the Medical Acts there is a general agreement. When proposals for the same take definite form medical men of each town and locality should hold meetings for their consideration. It is difficult to interest Parliament in Medical Acts. It is certainly not wise to be often disturbing the Acts or the bodies which administer them; but when the rare occasion arises for doing so the well-considered views of medical men would not be likely to be disregarded.

CANON WILBERFORCE UPON HOSPITALS.

WE have before now had occasion to take Canon Wilberforce severely to task for various statements which he made about hospitals, and therefore we have all the more pleasure in noting the moving and yet eminently sensible and sound discourse which he gave at Westminster Abbey upon Hospital Sunday. We do not suppose for an instant that Canon Wilberforce has changed his views upon the question of vivisection. We believe him to be perfectly sincere in those views, although mistaken, but we congratulate him upon being able to look at the question of hospital relief apart from the minor, or, if he prefers it, collateral question of experiments upon animals. That everyone cannot do this is apparent from the circular to which the preacher alluded, evidently the same document to which we referred in our columns of May 30th. Canon Wilberforce's remarks upon this subject were admirable, and it is a great pleasure for us to be able to say so.

THE PHILADELPHIA POLYCLINIC.

THE Philadelphia Polyclinic holds a special position among the hospitals of the Pennsylvanian city, being devoted entirely to post-graduate teaching. It is situated almost equidistant from the University of Pennsylvania, the Jefferson Medical College, and the Medico-Chirurgical College, and was opened early in 1883, its dispensary services treat about 15,000 new patients annually, and its course of study is based essentially on direct personal instruction by the teaching staff, which at present includes upwards of thirty-five professors and lecturers. There is an ample supply of clinical material. The new laboratory building is one of the finest in the country and is completely equipped with all modern appliances. Arrangements are being made to provide an exceptionally powerful "x" rays apparatus superior to the efficient instrument which is at present available for purposes of diagnosis, and Edison's fluoroscope will be used for direct visual observation of internal parts. The fees for the entire work and instruction in all the clinical departments are $90 for six weeks, and $150 for three months; pathology, bacteriology, operative surgery on the dead body, the putting up of fractures, dressings, and bandaging, &c., are extra subjects. The institution publishes a small journal which is likewise called the *Philadelphia Polyclinic*.

THE ABUSE OF TOBACCO.

SOCIETIES for the suppression of human frailty, though very numerous, are not as a rule remarkable for moderation; but, judging by their utterances, this reproach cannot with justice be levelled against the chief officials of a certain Parisian society whose object it is to prevent the abuse of tobacco. At a meeting held last April for the purpose of distributing prizes and rewards Dr. Gruby, the president of this association, commenced his inaugural address in the following reassuring terms. "The society against the abuse of tobacco proscribes the inordinate employment of that substance, but by no means condemns a moderate and judicious use. The very best things in the world are capable of producing injurious effects when taken to excess." Continuing his discourse, Dr. Gruby, as in duty bound, next proceeded to enumerate the various maladies and disorders which are supposed to attend upon indulgence in tobacco, but the list did not contain anything that was either striking or new. The general secretary, Dr. Gélineau, then read his report on the working of the society, winding up with the information that the executive intended to submit a petition to the Chamber of Deputies praying that "all telegraph messengers and schoolboys should be prevented from smoking, and also that tobacconists should be forbidden to sell their wares to mere infants whose lips should know no other pleasure than the cheeks of their mothers." Finally—after a disquisition from Dr. Edgard Bérillon on the treatment of *tabacomia* by hypnotic suggestion, and a lecture by M. Decroix on the dangerous progress of opium-eating in France—a lengthy roll of prize-winners was announced. First in order were several teachers, of whom one had founded a league against the abuse of tobacco amongst his pupils, while another had invented a copybook with headlines proclaiming the noxious effects of the direful weed. After the pedagogues came a sparse troop of omnibus conductors, whose claim to recompense lay in having interdicted smoking on the platforms of their vehicles; but the *lauréats* next on the list, although somewhat invidiously styled

Digitized by Google

"provincial" journalists by the metropolitan reporter, must surely be as rare in their profession as black swans were supposed to be when Juvenal penned his satires. Last of all—on the principle, we presume, that *finis coronat opus*—came the author of a formidable counterblast in the shape of a series of anti-nicotian sonnets; but there is apparently a limit to enthusiasm, even among zealots, and the verses were taken as read. The programme was now exhausted, but before the audience dispersed the secretary felt constrained to remonstrate with them on their excessive zeal. Most of the members, he said, were more royalist than the king. It was a fatal mistake to try to do too much. Tobacco has enough sins of its own to answer for without being made a scapegoat for half the ills that flesh is heir to. Moderation must be the watchword of the society if the evils which unquestionably do accompany the misuse of tobacco, especially in the case of immature boys, are to be remedied. It is to be hoped that these words of wisdom have been taken to heart by the hearers, and that no captious critic will accuse the society's officers of endeavouring at one and the same time to run with the fox and hunt with the hounds. It must be confessed that between the words and the deeds of these gentlemen there is a certain amount of incongruity; but then this world is full of contradictions.

THE PLAIN TRUTH AT INQUESTS.

TACT in the use of words is a faculty to be exercised by all sensible persons as long as this is consistent with a true and clear understanding. To medical men its employment is a daily necessity. Perhaps no class of men are more often called upon thus to clothe hard facts with a truly fitting dress of language. It is therefore the more important that they should not mistake the spurious for the real quality. Men are apt to fall into this error with the best intentions. We may be allowed to quote from recent experience of a coroner's court. On the occasion in question a medical witness, who had verified by post-mortem examination certain lesions due to alcoholism, very briefly described the death as due to "natural causes," his desire being if possible to avert the scandal of drunkenness. His was but a trifling error of judgment and it derives what little importance it possesses from its rather ungracious treatment by the presiding coroner. Had his evidence been stated with equal moderation but more precision it would still have been unexceptionable on the ground of good feeling and it would better have served its intended purpose, which was the enlightenment of the coroner and his jury. It is sometimes compatible with good sense and true kindness to speak plainly. This was a case in point.

ANNUAL PAUPER RETURNS.

THE Local Government Board have issued their annual return of paupers, including lunatics and vagrants, relieved on the first day of the present year, with comparative data for previous years. From this return it appears that, including 169 persons relieved both as in-door and out-door patients, the gross total of persons obtaining relief on Jan. 1st last was 840,625. On the estimated population of the Registrar-General this gives a rate of 2·8 per cent. of the population, or 1 person relieved in each 36 of the entire country. Of this total, 229,721 were in-door and 610,904 out-door paupers. The vagrant class accounted for only 13,239, including 7859 who were relieved in two unions on this same day. Only 390 of the vagrants were out-door relief cases. The in-door paupers include all those in Poor-law establishments such as district schools and the like. The able-bodied adult paupers relieved included 36,999 males and 75,380 females, and 168,669 children under sixteen years of age, the offspring of able-bodied paupers, were also relieved. The insane numbered 37,076 males, 46,379 females, and 1750 children under sixteen years of age. The ratio of paupers relieved to population was in England and Wales 27·7 per 1000; in London it was 28·2, in the eastern counties 37·1, and in the south-western counties 40·4. In-door paupers were at the rate of 7·6 per 1000 in the whole country, in Wales only 4·1, in Yorkshire only 4·5, but in London 15·8. As compared with the first day of 1895 the only groups of counties showing a decline this year were Yorkshire and the northern counties group. London showed an increase of 1·3 per cent., the north-western group of 3·0, the south-eastern and south midland of 3·1 and 3·5 respectively, and the north midland of 4·7 per cent. Throughout the country the increase was 1·6 per cent. Compared with earlier years the proportion of paupers to population was larger than on the same day of the five immediately preceding years, but smaller than in any of the years 1858–90 inclusive. In 1877, when the number of paupers was the smallest on record, the total was 12·8 per cent. fewer than in the present year. The able-bodied paupers were this year larger in their total number than in fourteen out of the twenty preceding years, but smaller than in the other eighteen years 1858–75. The data are given in detail for each of the Poor-law unions of England and Wales.

MEDICAL LONGEVITY.

DR. SALZMANN of Esslingen—who apparently is largely endowed by nature with a predilection for investigating the contents of ancient records, and who, more fortunate than the majority of his compeers, likewise enjoys exceptional facilities for indulging in his hobby—has recently devoted his attention to determining the average duration of life among members of the medical profession. After an exhaustive examination of all accessible archives referring to the last four centuries the following are the results arrived at by the zealous antiquarian. The average duration of a medical man's life during the sixteenth century was thirty-six years, five months; in the seventeenth century it was forty-five years, eight months; in the eighteenth century forty-nine years, eight months; and in the nineteenth century fifty-six years, seven months. It would appear from these data that—whether the survival be of the fittest or not—the duration of medical life has been increasing in a marvellous manner. Should the same rate be maintained practitioners of medicine may ere long all look forward to centennial honours—by no means a rosy prospect from the point of view of the neophyte who, as it is, finds it sufficiently hard to make good his footing within the densely crowded ranks. According to Dr. Salzmann the addition of over twenty years to the average medical lifetime is due to the advance of medical science, preventive and curative; so the ironical apophthegm, "Physician, heal thyself," can no longer be launched with any effect. In a speech delivered some time ago the present leader of the House of Commons alluded to the possibility of normal human life becoming extended "to the patriarchal term of 120 years." A fearful prospect truly in these days of rapid living when some men (having exhausted life's possibilities) look upon themselves as Struldbrugs at forty.

LIVERPOOL LADIES' CHARITY AND LYING-IN HOSPITAL.

A SPECIAL general meeting of the subscribers to the Ladies' Charity and Lying-in Hospital, Brownlow-hill, has been called for Tuesday next (23rd inst.), to consider the position. Mr. James Lister, the hon. secretary, states in a letter accompanying the notice that owing to the action of the medical profession the board of management had been unable to obtain the services of a medical staff. It is now

Digitized by Google

suggested that the general control in medical matters of all the cases should be placed under the hospital medical officers. The board of management is understood now to think it desirable that the rules should be altered in such a way as to admit of representation upon it of the medical staff. We heartily agree with the new views of the board of management.

THE CASE OF MR. R. B. ANDERSON.

MR. TIMOTHY HOLMES has given notice that at the forthcoming meeting of the Fellows of the Royal College of Surgeons of England to be held on July 2nd, he will move: "That the Council be requested to instruct its representative on the General Medical Council to forward in every way which seems feasible the objects of the Civil Rights Defence Committee in the case of Mr. R. B. Anderson." We invite every Fellow to support this motion. Mr. Anderson's wrongs are well known and we need not go into them now, but somehow or other his wrongs must be redressed.

COMMERCE AND PHILANTHROPY.

MR. WILLIAM COOPER of Stafford is doubtless a sound man of business. Doubtless, too, like Abou Ben Adhem, he desires to be written as one who loves his fellow men, but he has committed what we will mildly stigmatise as an error in taste. He has a business to sell, apparently a hotel with brine baths attached, and "as the success of this company will be largely dependent upon the support given to it by the medical profession" he makes the following offer—bribe we consider the proper word—to the medical profession:—

> The vendor undertakes, immediately after completion of the purchase of the premises and the receipt by him of the first instalment of the purchase money (which is fixed for the first day of September next), to pay to each subscriber to this issue who is also a duly qualified medical man, an underwriting commission at the rate of 10 per cent. in respect of shares, and 5 per cent. on debentures subscribed for and allotted to him, provided the contract to take such shares or debentures accompanying this prospectus is duly returned before June 20th instant.

There can be no doubt as to Mr. William Cooper's line of argument. It is a bribe to medical men to send patients to the Stafford Brine Baths Hotel and so increase the business done there, and Mr. William Cooper evidently thinks that if medical men have a pecuniary interest in the concern they will be the more likely to send patients to it. Besides baths, however, the medical man who comes to this lure will have an interest in a variety of commercial pursuits, as follows:

> To carry on the business of hotel, restaurant, café, tavern, beerhouse, refreshment room and lodging-house keepers, licensed victuallers, wine, beer, and spirit merchants, brewers, malsters, distillers, importers and manufacturers of aërated, mineral and artificial waters and other drinks, purveyors, caterers for public amusements generally, coach, cab, and carriage proprietors, livery stable keepers, jobmasters, dairymen, ice merchants, importers and brokers of food, live and dead stock, and foreign and colonial produce of all descriptions, hair-dressers, perfumers, chemists, proprietors of clubs, baths, dressing-rooms, laundries, reading, writing, and newspaper rooms, libraries, grounds and places of amusement, recreation, sport, entertainment, and instruction of all kinds, tobacco and cigar merchants, agents for railways and shipping companies and carriers, theatrical and opera box-office proprietors, entrepreneurs and general agents, and any other business which can be conveniently carried on in connection therewith.

All these businesses are perfectly legitimate and honourable, neither is there any reason why a man should not invest his money in any or all of them; but he should do so as a private individual and not as a member of a profession, which, equally with its sister faculties, ought to be above suspicion, even more than the London County Council.

GUARDIANS AS SANITARY AUTHORITIES.

THE return to sanity in guardians on the vaccination question is slow. In fact, it may be said that they have been tried as administrators of the Vaccination Acts and found wanting. The medical officer of health of Islington points out to the vestry that the proportion of unvaccinated children to those born has increased in that huge parish from 8·0 per cent. in 1885 to 18·0 per cent. in 1895. Mr. Harris was directed by the Public Health Committee in 1894 to represent to the guardians this grave state of matters, but nothing remedial has been done. In neighbouring parishes matters are as bad or worse. In Hackney, indeed, it is nothing short of a public scandal, the last available return showing that 41 per cent. of infants born remain unvaccinated. No wonder that the Vestry of St. Pancras has decided to convene a conference of delegates from vestries and district boards to consider the advisability of transferring the administration of the Vaccination Acts from boards of guardians to the sanitary authorities and that the sanitary committee of Islington has advised the vestry to appoint a deputation to attend the conference. On going to press we hear there is a localised group of cases of small-pox in Islington, which is likely to increase the earnestness of the vestry in this matter.

HEAT AFFECTIONS.

THE exceptional heat that has prevailed during the last few days has naturally been the subject of common remark. With each recurrence of hot weather we get, of course, its usual concomitants in the shape of discomfort, sleepless nights, more or less nervous depression, and affections attributable to heat fevers, heat exhaustion, and occasionally sunstroke, to say nothing of the distress to infants and children and their liability to attacks of indigestion and diarrhœa or nervous exhaustion. We do not think there is anything that can be said at the present time that has not been often said before. For those who live in the country surrounded by fresh air, who can dress in the lightest and coolest attire, and take their exercise when and how they like, hot weather is so enjoyable that a good many people revel in it. But it is a very different thing for those who are compelled to live in cities, to travel by underground railways, and to submit to the dust, closeness, and noise of London streets, and a succession of bands and organ-grinders, the practising of "scales" by inexperienced pianists, violinists, and vocalists, the yells of newsboys and race-card sellers, varied occasionally by the possible howling-whine of some pet dog that has been inadvertently left outside a house at night. Medical men cannot do much to relieve these sources of distress and discomfort; but a good deal may be done by the exercise of a little physiological intelligence and common sense to avert some of the other and graver effects of heat. Toleration of heat depends much on the vigour of the constitution, the state of the health, and the mode of living, especially in freedom from excess in alcohol and food, in being suitably appareled, and in getting all the air and ventilation that are available. We need not dwell upon the different forms of sunstroke and heat affections; they are pretty well known. Among the gravest of them is the exhaustion caused by heat which is followed by syncope, a condition allied to shock from the effect of a powerful sun on the nerve centres, especially the respiratory centre, and that form attended with the over-heating of the blood and all the tissues of the body. Men on parade or when marching, if oppressed with accoutrements and clothing, or when occupying heated and badly ventilated barracks in tropical or subtropical climates, are very apt to suffer. A dry heat, it is well known, is better tolerated than a moist one, and we have evidence of this in the experience of our soldiers in the present Soudan campaign. The treatment obviously cannot be the same in all cases, but where a high body temperature is a characteristic feature of the attack cold is the remedy—cold water, ice, and exposure to currents of air. The great heat of Saturday last resulted in three cases of sunstroke, one of which ended fatally, in the Royal Irish Rifles on their march from Lydd camp to Brighton. We can all of us, at any rate during exceptionally hot weather, try to keep quiet and abstain from "worritting" ourselves and other people, and

Digitized by Google

clothe and eat lightly. For children who feel the heat there is, of course, nothing like removal from towns and cities to seaside and country places.

ST. MARY'S HOSPITAL: CLARENCE MEMORIAL FUND.

THE festival dinner of St. Mary's Hospital was held in the Whitehall Rooms of the Hôtel Métropole on Wednesday last, Sir Wm. Broadbent presiding, and resulted in the addition of nearly £4700 to the Clarence Memorial Fund. This sum represents only one third of the amount which is required to complete the new buildings, and owing to the inadequacy and unsuitability of the present out-patient department it is most desirable that the work should be carried out immediately. In addition to a new out-patient department the Clarence wing will comprise a nurses' home, lying-in wards, various special wards, and a medical college. These are all urgently needed in a hospital whose original accommodation for some 70 or 80 in-patients has been stretched to a limit of 281. If the hospital is to adequately fulfil its function of ministering to the sick poor in a vastly crowded portion of the metropolis there must be no delay in building the first portion of the Clarence wing. We earnestly hope, therefore, great as have been the demands upon the benevolent lately, that they will allow a portion of their charity to flow towards a most deserving institution. With the exception of the £4700 consequent on the festival dinner the whole of the funds have been absorbed in the building of the basement.

A PROTEST AGAINST THE USE OF ALKALI IN COCOA.

FROM practical experience gained in THE LANCET Laboratory during the past year it is evident that the practice of treating cocoa with alkali is largely on the increase. It is done ostensibly, we believe, to render the cocoa more "soluble"; in reality the cocoa fat is in part by this treatment saponified, so that the infusion made with it presents the appearance, and conveys to the palate the impression, of a richer and more full-bodied beverage. In addition the powder is considerably deepened in colour, which is probably and wrongly judged by an ignorant public to indicate richness of quality. If it were necessary to treat cocoa in this way in order to make it palatable and digestible we should have nothing to say; but it is not so, and that being the case it constitutes a mild but distinct form of fraud. We go further and enter a protest against this treatment of cocoa with alkali because we are confident that in many cases it may be productive of harm. It must be remembered that invalids and those suffering with certain forms of weak digestion are in a great number of cases prohibited the use of tea and coffee, and cocoa is invariably recommended as a substitute. Moreover it is well known that the long-continued use of alkalies leads to digestive disorder and consequently impaired nutrition. Yet we have examined cocoas containing from 1 up to as much as 3 per cent. of alkali calculated as potash. Cocoa the indigestible fat of which has been properly reduced to 30 per cent. by pressure in hot bags contains at the most only ½ per cent. of alkali. We have examined such cocoas which leave nothing to be desired as regards quality and flavour, while further tests have also shown the absence of an excess of nitrogen in the form of ammonia. This is why we believe that the treatment referred to is wholly unnecessary. We call attention to this fact because we believe that many medical men are not aware of it, and in certain cases under their care it might well happen that the exhibition of alkaline fluids as such cocoas would yield is very distinctly contra-indicated. It is absurd for manufacturers to argue that it is done to please the public taste. The same thing was urged long ago in regard to white bread; but the public have since been undeceived, and an enormous demand has arisen of late years for an unbleached, a healthy-looking, and an unimpoverished loaf. We hope the public will assert their good sense in a similar way in regard to cocoa.

QUALIFIED *v.* UNQUALIFIED.

THE public will, we suppose, to the end of time continue to exemplify the Horatian maxim about wishing to be deceived, and a most instructive case is reported from Grimsby. Alfred Barnes claimed £50 damages from two bone-setters named Bromfield, carrying on business in Grimsby, for unskilful treatment. On Jan. 20th he knocked his shoulder. On Feb. 1st he consulted Mr. Alexandre, a duly qualified medical man, who found nothing wrong with the joint, but did find an enlarged axillary gland, and recommended rest and poultices. On Feb. 7th Mr. Barnes consulted the Bromfields. Bromfield, sen., according to Bromfield, jun., said "the fat muscles were wrong," and pulling his knee in the axilla wrenched the joint. He, Bromfield, jun., put his hand on the patient's shoulder and felt the muscles "go." Eventually a large abscess formed and Mr. Barnes returned to Mr. Alexandre, who treated him for this. Mr. Barnes contended, and so did Mr. Alexandre and two other medical men, that the Bromfields' treatment had caused this abscess. On the other hand two medical men said that this could not be the case. The anatomical knowledge of these latter gentlemen is defective, for they both, according to the *Grimsby Independent*, said that an axillary abscess could not be diffused. The jury returned a verdict for the Bromfields, their solicitor pointing out that there was no law against a man practising as a bone-setter without a medical qualification. This is quite true, but there should be. We are sorry for Mr. Barnes' original accident, but he does not deserve the least sympathy for the results which followed. Perhaps, some day the legislature will wake up and come to the conclusion that if it obliges medical men to spend five years and a large sum of money in educating themselves they ought to be protected against those who have no qualification; and, moreover, since the law will not allow a man to sell a pint of beer, an ounce of tobacco, or buttons or pins in the street, without paying for the privilege, the law might also insist on an unqualified practitioner paying a small sum, say £200, for the privilege of dabbling in the economy of a fellow creature.

THE LAW AS TO THE SUPPLY OF POISONS.

THE evidence given at the inquiry into the death of Professor Middleton reveals, or perhaps we should say draws attention to, the very dangerous state of matters in regard to the supply of poison by prescription. The following is the evidence of the druggist as reported in the daily press. Thomas Henry Keen, a druggist, of 9, Bruton-street, W., said he supplied the deceased with a solution of morphia made up from a medical man's prescription. He had had it for twenty-two years, and the strength was 1 in 20. He usually purchased twenty-four bottles at a time, half of which were packed up ready for abroad. Each bottle contained twenty-four grains of essence of morphia. He had not seen Professor Middleton for some time. The morphia did not require signing for, as it was a prescription, so that there was no breach of the Pharmacy Act. What "essence of morphia" is we do not quite know, but one fact is clear. Here was a man able to supply himself for twenty-two years with a powerful drug, not in small quantities but in large, and that too on the authority of a single prescription written, we suppose, twenty-two years ago. The druggist was perfectly within his rights as the law stands, but we contend that the law should be

Digitized by Google

altered. Prescriptions such as this ought to be endorsed by the physician in some such way as the following: "This prescription is not to be dispensed oftener than ——— without a fresh signature from me." In any hospital even so simple a thing as the ordinary gentian and rhubarb mixture is not supplied time after time without the authorisation of "rep. 14 days," or something of the kind, and if in addition the druggist were compelled to stamp the prescription with a date every time he made it up the patient could not go from one druggist to another, as is occasionally done now, and buy, say, one drachm of the drug he seeks from each. We suppose that any proposal of this sort would meet with the usual silly opposition, and cries of interference with personal liberty and fettering of commerce; but if our parental legislators prevent small boys from playing pitch and toss or "run in" the hard-working and industrious vendor of surprise packets we do not see why they should not try, at any rate, to protect the community from being able to poison itself.

THE annual dinner of the Oxford Medical School was held on June 13th in Magdalen College Junior Common Room (by permission of Mr. H. D. G. Leveson-Gower, president). Professor Arthur Thomson occupied the chair, and amongst those present were the Regius Professor of Medicine (Professor Burdon Sanderson), Professor Howden (Newcastle), Professor Gotch, Dr. J. Ritchie, Dr. G. Farmer, Dr. G. Wilson, Dr. F. G. Proudfoot, and Mr. H. P. Symonds, Mr. A. Winkfield, Mr. L. L. Morgan, &c. There were between forty and fifty present and everything was completely successful. Mr. F. P. T. Hilliard (Magdalen) acted as secretary and treasurer. The ménu card, a very clever design by Mr. C. L. Pilcher (Keble), we hope to reproduce in a coming number.

THE Colonial Office has learned by telegram from the Governor of Hong-Kong that there were 27 fresh cases of bubonic plague in the week ending June 15th and 22 deaths from the plague during the same period.

THE annual general meeting of the Society of Fellows of the Royal College of Surgeons will be held at 146, Harley-street, W., on July 1st, at 5 P.M.

DR. RALFE has resigned the post of Physician to the London Hospital, after sixteen years' service, and has been appointed Consulting Physician.

THE annual mess dinner of the Volunteer medical officers will take place at Limmer's Hotel on Saturday, July 18th.

INTER-HOSPITAL BOAT RACE.—Upon June 11th the annual Inter-Hospital Boat Race from Hammersmith to Putney took place in brilliant weather and was witnessed by a large assemblage. Three hospitals were represented—viz., Middlesex Hospital, Middlesex Station; St. George's Hospital, Centre Station; and London Hospital, Surrey Station. At the first attempt a foul took place between St. George's and Middlesex, and the crews were ordered back to the stake boats. After a short delay, necessitated by the rupture of a thowl string in the St. George's boat, a fresh start was made. Another slight foul between St. George's and London enabled Middlesex to get away with a slight lead. A grand race now ensued for the first mile between Middlesex and St. George's, the former, however, gradually increasing their lead. At the point opposite to the Ranelagh Club the St. George's crew were evidently beaten, and the Middlesex, holding the race well in hand, passed under Putney Bridge with a clear lead of two and a half lengths. London, who rowed a plucky stern chase, finished five lengths behind. The winners covered the course in the excellent time of nine minutes and three seconds.

THOMAS WAKLEY,

THE FOUNDER OF "THE LANCET."

A BIOGRAPHY.[1]

CHAPTER XXIV.

Proceedings at Bow-street.—Wakley continues to fight.—The College institute Criminal Proceedings. — The London College of Medicine.—Its Prospectus.—Its Failure.

SIR RICHARD BIRNIE and his fellow magistrates after deliberation decided that they could not grant Wakley a warrant against Ledbitter, the Bow-street officer who had assaulted him. The reasons for this were not made very clear in words by the worthy knight, who frankly confessed his partial feelings in the matter. He seems to have considered, first, that Wakley was debating in the building of the College affairs that were not collegiate, and that, therefore, the President of the College had a right to have him removed. To this Wakley said that the wrongs of the naval surgeons, whose diplomas and certificates were very generally granted to them by the College, were exactly matters of the highest collegiate as well as professional interest, and that even had they been otherwise the man Ledbitter had struck out at him with his truncheon in a murderous way. Sir Richard Birnie then said that Ledbitter was wrongly arrested, inasmuch as the Bow-street officer who had taken him in custody was not an actual eye-witness of the alleged assault, and it was a general instruction to the Bow-street officers that they should only arrest a man for a wrong-doing of which they had personal ken. To this argument, which was unfavourably criticised from the bench by another magistrate, Wakley responded by exhibiting his ruined clothes to the court and asking if there could be any reasonable doubt that he had been savagely assaulted. The Bow-street officers themselves, moreover, admitted the truth of Wakley's account, merely saying that they had received their instructions upon two separate occasions from the Council of the College to expel Wakley; and they identified a person in court, who turned out to be Mr. Wilde, the solicitor to the College, as the individual who had told them that for whatever they did the authorities of the College would hold them indemnified.

As Sir Richard Birnie would not grant a warrant the matter ceased there as far as legal proceedings on Wakley's part were concerned. Some preliminary steps were taken to bring Ledbitter to justice in another way, but Wakley was not truly desirous of prosecuting the man and did not persevere in the face of tedious formality. If he could have prosecuted the Council of the College for the assault he would have done so; this he said repeatedly, and no one can doubt that he meant what he said, but he was advised that his chance of making out a legal case against them was slender. A moral case, however, was easily to be established against them, and Wakley's pen was not idle. It is characteristic of him that after one powerful outburst of rage, his allusions to the personal indignity that he had undergone became infrequent and dispassionate. The fact that the Council had expelled him by violence and with the assistance of Bow-street officers from the theatre of the College added no bitterness whatever to his strictures. In fact, after the first natural feeling of wrath and insult had subsided he was not ungrateful to his enemies for providing him with so graphic a proof of his contention that they

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., XVI., XVII., XVIII., XIX., XX., XXI., XXII., and XXIII. were published in THE LANCET, Jan. 4th, 11th, 18th, and 25th, Feb. 1st, 8th, 15th, 22nd, and 29th, March 7th, 14th, 21st, and 28th, April 4th, 11th, 18th, and 25th, May 2nd, 16th, 23rd, 30th, June 6th, and 13th respectively.

Digitized by Google

were autocratic, careless of the rights of their commonalty, and unscrupulous in their methods of preserving their own position as irresponsible rulers. These three propositions he demonstrated week after week ceaselessly and remorselessly, and concluded by recommending the London students not to affiliate themselves to the College of Surgeons at all but to be content with the licence of the Apothecaries' Hall, which Company charged less in fees and did more to protect its general body. His argument in support of this advice to students was ingenious. It was based on the working of the Apothecaries' Act of 1815, which had been unduly pressed by the Apothecaries' Hall against the College of Surgeons, properly qualified surgeons having been prosecuted by the Hall for dispensing medicines. The Hall, in fact, took active and selfish steps in defence of those possessing its licence, and Wakley, whilst reprobating the institution of prosecutions against the Members of the College of Surgeons, advised the coming men to join the Hall.

This advice may or may not have stung the Council of the College into reprisals; it was calculated to damage the corporate purse, which Wakley said was the tenderest spot in the Corporation, but certainly their next move was a strong and almost unwarrantable one. It was no less than a motion for a rule in the court of King's Bench calling upon Thomas Wakley, Thomas King, George Walker, and George Darby Dermott (whose name had not previously been conspicuous in the proceedings of the reformers) to show cause why a criminal information should not be filed against them for certain misdemeanours committed in the theatre of the Royal College of Surgeons of England on the occasion of the riotous proceedings at the College in protest against the exclusion of the naval surgeons from the King's levées. The motion was heard by Lord Tenterden who made the rule absolute against Wakley and King, and discharged it against the other defendants, stating in his remarks from the bench that it was illegal for the Members to discuss in the theatre of the College any subject not connected with the acknowledged duties of the Corporation.

Wakley undismayed responded with an entire elaborate and cut-and-dried scheme for a new corporation of surgeons to be entitled the London College of Medicine, to have a Royal Charter and to do everything as properly as the existing College did everything improperly.

The London College of Medicine was really a socialistic dream. The idea of founding such an institution undoubtedly sprang up in Wakley's mind as the swiftest and most drastic method of punishing the College of Surgeons. When he formulated the scheme for it he was not in a mood to weigh matters as calmly and judiciously as was his wont, for undoubtedly a great sense of personal anger had been roused in him by the institution of criminal proceedings against him. This bent his judgment, which had not been warped in the least by the violent physical treatment that he had received. He over-estimated—and for the first time—the power of his pen. As a destructive weapon it had proved terrific; he now proposed to employ it in construction. The London College of Medicine, "founded upon the most enlarged and liberal principles, in which all legally qualified practitioners, whether physicians, surgeons, or apothecaries," were to be "associated upon equal terms" and to be "recognised by the same title," was obviously fore-doomed to failure. Below is an abridgment of its prospectus, by which it will be seen that its constitution was really an attack on the College of Surgeons. The new College proposed to do for the public and the profession everything that the old one did not do, and for the neglect of which the more advanced reformers found such bitter fault with it. After a preliminary clause stating that all persons in the United Kingdom at present holding a medical or surgical degree or diploma were eligible to be chosen as Fellows without examination, it proceeded as follows:—

The possessors of the diploma of the London College of Medicine are denominated Fellows, and will enjoy, both in and out of the College, the title of Doctor.

The London College of Medicine will be under the government of a Chancellor, Vice-Chancellor, and Senate.

The Senate will consist of not less than thirty-six Fellows elected by ballot, annually, by the Fellows in general convocation.

The Chancellor, Vice-Chancellor, and Scrutators are elected by the Senate; a majority of the Senate to be present, or the election void; the elections to be conducted by ballot, and the decision of the majority, final.

On each examination of candidates for the diploma, seven of the Senate constitute a medical jury; the Scrutators are ineligible to the office of jurymen.

On each examination the votes of a majority of the jury to decide the candidate's admission or rejection.

The examination of candidates will be conducted in public by the Chancellor or Vice-Chancellor, the Scrutators, and the medical jury.

Candidates are not required to produce any certificates whatsoever; the capability of undergoing a fair and searching professional examination being considered the only professional qualification necessary for obtaining the diploma.

The fee demanded for the diploma of the College is three guineas from gentlemen engaged in practice, and five guineas from students. No candidate after a second rejection to be eligible for re-examination until twelve months shall have elapsed.

Wakley went to his personal friend, who was to be in the immediate future his political god-father, Joseph Hume, for assistance in the matter, and Hume consented to take the chair at the preliminary meetings, which were enthusiastic entirely because Wakley's strictures against the College of Surgeons were so forcible and so amusing. Hume had once been a medical man, but his whole career was now political, and he really did not understand the nature of the departure he was being made to float. If Wakley had submitted his scheme to any man of Hume's talent but who was in touch with the needs of the profession, a lecturer or a man with experience on a hospital staff, he would have received criticism and guidance that would have prevented him from pursuing with so much energy such a will-o'-the-wisp as the scheme for founding the London College of Medicine was bound to prove. But Hume, a reformer and a great politician, almost a statesman, was quite ignorant of the true needs of the medical man or the real extent to which the College of Surgeons had abused its position. He was informed by Wakley, who was too angry at the time to be able to inform him quite impartially, and so when things were referred to his judgment he could only frame an answer in accordance with one-sided information.

But in the absence of competent advice Wakley, with immense perseverance, wrote up the cause of the London College of Medicine, where the ruling body was to be elected by universal suffrage; where there were to be no grades of rank or distinctions in title; where no monopoly in the teaching or the granting of certificates to the taught was to be countenanced; where the fees were to be low and only the standard of courtesy between examiners and examined high. But write as he would he could not galvanise this stillborn scheme into life. It was without the elements of existence. To begin with, unless the Government granted the promoters a charter their association among themselves was no use. Unless the State recognised the diplomas of the new college there would be no inducements to candidates to present themselves to obtain them. Now it was not for a moment probable that Government would have anything to do with the new scheme. A Royal charter had been granted to the College of Surgeons together with much money. Against this charter

Digitized by Google

a petition had been presented to Parliament which had so little to recommend it to the notice of the House that after a perfunctory order to the impeached corporation to present certain accounts the matter dropped out of notice. The House would certainly consider the new scheme the outcome of private ill-will against the officers of the older body, who had already been recognised by the Crown and were in receipt of public money. To support a rival body designed in every way to ruin that corporation would be to stultify the action of the Crown in granting the charter and to waste the money already granted with no niggard hand. So that if Wakley had been supported by the mass of the College in the way that he confidently expected he had nothing to hope for from Government. But as a matter of fact for the first time the better sort of his own particular followers and readers were not wholly with him. They admitted the perfect unselfishness of his project, but they did not want it. They had no real hate of their College or its authorities. They desired it to be reformed and they thought that Wakley might reform it. But they did not want it destroyed and a new institution with no history and no prestige substituted for it; so that the London College of Medicine died of inanition before anyone save its inventor and a few ardent and not wholly disinterested colleagues would allow that it had ever been born.

The criminal proceedings against Wakley and King also came to a speedy termination. Though supported by Lord Tenterden's rule and dared by Wakley to proceed, the Council decided to let the matter drop. So that the outcome of the great and stormy meeting of Feb. 14th, 1831, was nothing at all save that the naval surgeons were re-admitted to the King's levées, to agitate for which was the reason that Wakley summoned the Members together. Wakley was advised that he could not prosecute the Council, and he did not desire to prosecute Ledbitter. The Council having been successful in their initiatory steps against Wakley decided that it would be impolitic to proceed further. The London College of Medicine, instituted to meet the wants of the rank and file of the profession and to take the place of the College of Surgeons, whose behaviour towards its members was so ruthless, came to an early and inglorious end.

(To be continued.)

THE ROYAL MILITARY TOURNAMENT.

To state that this year's meeting at the Agricultural Hall has been a successful one in all respects is to convey but an inadequate impression of the entirely satisfactory nature of the financial results of the show, which, we believe, have completely eclipsed any former record. Crowded afternoon houses day after day and overcrowded evening houses were the rule, with hundreds unable to find seats or standing room, walking about the gangway encircling the arena content to listen to the band and see what could be seen of varied uniforms, magnificent horses, and wonderful guns. Lord Methuen and his committee of management, though hampered by many unforeseen obstacles, have not failed to organise an entertainment quite equalling any presented in former years.

As one of the features of the London season the Royal Military Tournament has undoubtedly taken firm root and become dear to the heart of the public; and in view of the keen interest evinced in the show by all classes—an interest practically demonstrated by the thousands turned away at the doors for want of accommodation—it may not be out of place to suggest to the committee that the time has arrived for providing this great yearly fixture with a more suitable abiding place. The Agricultural Hall, though large, is neither sufficiently large nor commodious enough either for the men, horses, and guns which provide the spectacle, or for the overwhelming multitudes that throng to witness it. Though much has been done to improve the accommodation, lighting, ventilation, and general sanitary arrangements at the hall, it must be conceded that the building in many respects is unworthy of the great military gathering of the year. Its situation is by no means central, its approaches cannot be said to be good; and for want of space the unavoidable mixing up of perambulating audience, performers, horses, and artillery in a narrow circular passage within the building is neither satisfactory nor safe to the visiting public.

In all contests in which strength, swiftness, and equestrian exercises are concerned accidents to competitors may be looked for, and this year's tournament, though comparing in this respect favourably with bygone meetings, has not passed without casualties. At the rehearsal before the opening performance Captain Cowie, R.E., who was superintending the attack on the Afghan Fort at the end of the arena, fell from the trestle bridge, some sixteen feet, upon some planking below, alighting in a sitting posture upon the ischial tuberosities. On examination no fracture was apparent, but this officer has suffered much since from shock and contusions, the last account of him being that he was doing well though still confined to his bed. It is only right to mention that Captain Cowie came by his fall in a generous effort to prevent five or six other men from reaching a plank gangway which he thought insecure. On the morning of Thursday, June 4th, First-class Sergeant-Instructor of Fencing Foerster, Army Gymnastic Staff, who was judging at sabre practice for two officers, was the victim of a very lamentable accident. In his eagerness to judge correctly Sergeant Foerster happened for an instant to approach too closely the arc described by the sabre of one of the combatants, who was suddenly swinging it back to deliver a back-handed cut, when the tip of the sabre struck and completely ruptured the globe of Foerster's right eye with escape of the vitreous; the globe was so much disorganised that it was decided to extirpate it next morning. On Friday, the 5th, at the rail jump in the arena the horse of Rough-Rider Sergeant Rumsey fell and rolled upon him, causing temporary collapse; it is supposed that the cantle of the saddle came into violent contact with the abdomen as there has been much tenderness accompanied with some bruising, but with no rise in temperature or other grave symptoms since. With the exception of a slight concussion from a fall from a restive horse upon the paving outside the entry to the arena no other accident of importance occurred amongst the troops quartered at the hall. Various minor casualties occurred: a sprained knee from jumping, sundry contusions due to kicks from restive horses in stables, and some slight bruises and lacerations in the several competitions—in, for example, bayonet *v.* bayonet, in which Corporal of Horse Elliott sustained a contused and lacerated right thumb, which probably might have been averted had the right as well as the left hand been gauntleted. Most of the accidents recorded at this and at similar meetings have had their origin in the undue eagerness and haste of the competitors, a species of carelessness which it is difficult to prevent. The management, indeed, does its utmost to guard against casualties by insisting that the usual school of arms clothing shall be worn by all competitors—viz., helmets, masks, gauntlets, sporrans, padded jackets, and so forth—and it is to be congratulated upon the excellent condition of the arena this year, as proved by the non-occurrence of any overturning of the guns in the horse artillery galloping, of which this tournament has seen more than usual. We may suggest to those responsible for the furniture of the ring, however, that the rail jump should be invariably whitened, and that a thick layer of tan might with advantage cover the floor over which any future trestle bridge may be erected in a combined display. And, further, that those judging at sabre competitions as well as the competitors themselves should wear masks.

We are glad to note that since last year the free circulation of air throughout the building seems to have been secured, the temperature during an evening performance inside the arena being by no means oppressive; this improvement is partly due no doubt to the increase in the number of electric lights and the almost total abolition of gas as an illuminant. The removal of the greater number of the horses also to new stables adjoining the main building has further improved the atmospheric conditions, and the noticeable absence of ammoniacal stable effluvium was no doubt due to the free use of peat-moss litter, which we understand is coming into general use in our cavalry stables.

As in previous years, a temporary station hospital for the troops of two beds was established in a hut within an

Digitized by Google

enclosure at the eastern end of Barford-street immediately outside the Agricultural Hall. Any accident or case of sickness requiring nursing was housed here for a night or so only, being transferred to the district hospital at Rochester-row as early as possible. A detachment of the Medical Staff Corps furnished orderlies for nursing duties at the Barford-street hospital, and a bearer-party with stretcher and all First Aid requisites was stationed under the Royal box during the whole of each performance, one medical officer also invariably being on duty in the judge's enclosure. As we have previously stated, the principal medical officer was Surgeon-Major Alexander, Coldstream Guards, whose arrangements for the immediate treatment of accidents were most excellent, assisted by Surgeon-Major Lawless, A.M.R., and Surgeon-Lieutenant K. Cameron, A.M.S.

The quantity and quality of the rations supplied were excellent, and the water-supply, lavatory, and latrine accommodation for the troops appeared to be ample. The men slept in cubicles on the gallery floor, as during the last two tournaments. As much as possible was done, by instituting cross ventilation, to render the atmosphere pure at night; some of the stables, however, appeared to us to be very oppressive, the probable explanation of this being the large amount of glass roofing used in their construction. Last year we called attention to the inconvenience caused to the men by the hot rays of the sun pouring through this glass roofing, and suggested as a preventative measure the use of a strip of canvas. We are glad to be able to report that this has been noted by the new committee and the roofing over the galleries has been distempered with whitewash. Another desirable improvement, due, we believe, to the indefatigable secretary, Major Eyre Crabbe, is the provision of baths for the men. These have been greatly appreciated.

We again draw attention to what we consider a danger to public safety—viz., the possibility of kicks from horses, &c., to people admitted through the Upper-street turnstiles, who, to reach their seats, must frequently pass behind a row of horses drawn up and about to enter the arena. An alley-way could easily be devised through St. Stephen's Hall by which this danger would be minimised. The proprietors of the hall might with advantage, we think, provide more than one cloak-room and lavatory for ladies.

Upon inquiry we ascertained that for this large muster of troops only one temperance bar had been provided by the contractors. We offer the suggestion to Messrs. Probyn and Co. that an additional temperance bar should be opened on the ground floor of the hall, and though officers and the general public may perhaps be charged fancy prices for mineral waters and other temperance beverages—we do not, however, approve of this—the private soldier, with his hard-earned, scanty pay, should not pay other than canteen prices for them. It is quite possible to make a respectable profit and at the same time to supply the soldier with ginger-beer, soda water, &c., at 1*d.* a bottle.

Chief-Surgeon Osborn, Dr. Harris, Dr. Hunter, with others of the St. John Ambulance Association, with a party of attendants of the St. John Ambulance Brigade, established an ambulance station in the arcade, where first aid was given in minor casualties of the kind usually found in any great concourse of spectators. We visited the ambulance station in the arcade, which consisted of one small cubicle, and appeared to serve for the reception both of female as well as of male applicants. We can scarcely congratulate the Tournament Committee this year upon the change that has been made in doing away with the very efficient ambulance service which gave so much satisfaction to the public for the last four years, a service which provided two well-equipped but separate receiving rooms for the treatment of male and female accident cases. This was as it should have been, and if the change has been made on the score of economy we cannot help being of opinion that the economy was ill-advised. Altogether, about 800 men, 390 horses, and some sixteen field guns were engaged in this year's tournament.

The general health of the troops has been excellent, and where as many as 800 or 900 men are gathered together from all parts of the kingdom under one roof and under many trying conditions this is no small matter, and speaks well for the general care of the soldier evinced by those responsible for it.

At some of the evening performances the overcrowding amongst the shilling spectators, wedged together in one enormous mass, was somewhat alarming. That this was felt to be so was proved by the request of a certain number to be released from the tightly packed crowd. This could only be done by hauling out individuals here and there into the arena. It is this vast shilling audience, hitherto provided with standing room only, which by its nightly patronage so largely contributes to the tournament treasury, and we venture to suggest to the management that some seating accommodation, tier above tier, might be provided for it. On the score of public safety it would be desirable, and as there would thereby be less restlessness and shifting in the crowd, it presumably would do away with much of the nervous fright of the horses which is so apparent and pitiable to witness when they have to make the circuit of that side of the arena.

Veterinary-Major Rowe, of the Home District, was the principal veterinary officer in charge of the horses, which were probably more numerous at the Agricultural Hall this year than at any former tournament.

THE ANNUAL REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1894.

[CONCLUDING NOTICE.[1]]

IN our last notice we passed in review and commented upon some of the points raised in the Sanitary Commissioner's report connected with the great prevalence of enteric fever among the European troops serving in India, as compared with that of the native army and the gaol population, and alluded to the great and apparently increasing drain and lamentable loss of life caused by that disease on the young manhood of the European force in India. We also adverted to the excellent analysis of the current views held by pathologists and epidemiologists in regard to cholera set forth in the sixth section of that report. We purpose now to touch upon some points connected with malarial fever, dysentery, and hepatic abscess, but before doing so would call attention to some general points that appear to merit consideration.

In the report of the Royal Commission on the Sanitary State of the Indian Army issued in 1863 the estimated mortality of the Company's troops during the years from 1800 to 1856 is stated to have oscillated between 69 and 70 per 1000. The Royal Commission, in calculating the saving of "army life" that might be effected by the application of ordinary sanitary methods, said that the death-rate of 20 per 1000 ruling among Indian Civil servants ought to be attainable for soldiers. They went beyond this and expressed a belief that in times of peace the death-rate among men of soldiers' ages in India might even be reduced to 10 per 1000 per annum, and subsequently in 1883 it actually was only 10·88 per 1000. Of course, the death-rate of a single year cannot be accepted as an indication of permanent improvement. India is the land of epidemics, and the presence or not of such disease-causes will make all the difference; but, allowing for ordinary fluctuations, the sickness and death-rate of late years among European troops in India seems to have been increasing on the whole, and we appear to be losing some of the ground that had been previously gained in this respect, notwithstanding that the ratios are, of course, far more favourable than they used to be when the life-conditions and environment of the British soldier serving in India were so different to what they are now. Prior to the introduction of the short-service system and apart from sanitary changes that have since been effected in India, the men were much older and of longer service, and they died from diseases incidental to service in hot climates under those conditions, whereas now that they are much younger and have relatively short periods of service in India they die disproportionately from enteric fever. It would be interesting to institute a comparison between the death-rates of men of thirty years of age and over and those of soldiers of from twenty to twenty-five years of age from enteric fever and the diseases which are especially incidental to young soldiers recently arrived in India. We require, if possible, to have some plain tabular statement of the loss and gain in these respects and of the actual, and

[1] The First and Second Notices were published in THE LANCET of May 9th and 16th, 1896, respectively.

Digitized by Google

not merely the apparent, improvement which has taken place. It is very difficult amid the numerous and voluminous tables in the report for the reader to find out exactly what he wants to know. Does the increased liability of the young and recently arrived soldier to die from enteric fever counterbalance or not the greater liability of older soldiers of longer service in India to die from other diseases? While there is a very gratifying reduction in the death-rates from the more important diseases this is certainly not the case as regards enteric fever, for it has for some years past been the most important disease-cause in the Army of India.

While on this subject we would also suggest that not only should the health statistics be tabulated for corps, but for the stations and barracks occupied by them. If this were done locally for some years, as it probably is, the topographical medical history of every military station and of the various barracks in them could be registered and preserved for the guidance of successive military and medical authorities in locating the troops and in forming an estimate of the nature and amount of the diseases that might be expected to appear in different localities and barracks in a given time under given conditions. To this should be added a topographical description of the stations and barracks, with their food and water supplies, camping-grounds, &c. In that way we should have a valuable continuous record of the accumulated and accumulating results of local medical and sanitary experience. Moreover, it seems to us that, in addition to headquarters' sanitary bureaux and bacteriological institutes, there should be some organised method for having the causes of any local outbreaks of disease inquired into at once, with a view to the prompt application of practicable remedial measures. For this purpose there should be some public health organisation and officers, with a local board composed of an officer of the Public Works Department with a special knowledge of sanitary engineering, a medical officer specially skilled in hygiene, and a member of the Quartermaster-General's Department in every military district or large station cantonment, for the purpose of undertaking such investigations whenever their services were called for. The application of the results of bacteriological researches to the investigation of disease-causes is an essential part of the sanitary organisation; but it is, after all, only a means to an end. A practical sanitary machinery is necessary to carry on effective work in this direction. However interesting it may be in a scientific sense to demonstrate the existence of a special parasitic micro-organism in connexion with any given disease, the practical utility of such a discovery is small if we are merely to content ourselves by relegating it to that as the cause.

As regards malarial disease in India, the climatic difficulties, the comparative absence of drainage works, and the great and prohibitive cost of their construction, together with the poverty and ignorance of the natives, undoubtedly form enormous obstacles in the path of the sanitarian. Still, the sanitary history of London in the middle ages is the history of all old neglected towns and the remedies are very much the same. London with its vast population has been cured by the drainage of the subsoil and houses, by rapid removal of sewage to a distance, by closing wells and substituting water of better quality, by good paving and surface drainage, and by rigid attention to cleanliness. The practical remedies for malaria in many parts of India are to lower the water level and increase the movement of the subsoil water. Ague gave rise to about 27 per cent. of the admissions from all causes in the European army in India. Section 6 of the report contains a reference to the investigations into the micropathology of malarial fever that have been carried on in many parts of India, especially by Surgeon-Major Ronald Ross in Madras, Surgeon-Captain Murray in the Punjab, and Surgeon-Captain Maynard in Calcutta. Ever since the discovery of Laveran's blood parasite medical officers in India have naturally been keenly interested in the subject. A considerable amount of work has also been done by Carter, Cunningham, and Crombie.

Dysentery was, as usual, most prevalent in the Madras army. The number of deaths from hepatitis was increased in 1894 by twenty-three. The percentage of hepatic abscess in the total causes of death was highest in Burma Coast. The remarks on the relative prevalence of dysentery and hepatic abscess among European troops, native troops, and gaol population, and the pathological observations on these diseases with references to recent literature on these subjects contained in the sanitary commissioner's report, are well worth reading. That there is a real connexion between the two diseases may be considered as a well-established fact. The origin of this abscess seems, however, to be also dependent on some climatic influences. Europeans in the tropics are more liable than natives and the same is the case in Egypt. Apart from dysentery, hepatic affections and abscess are frequent among European residents. The natives of India are more liable to dysentery and malarial fever, but less liable to hepatic abscess, than the European temporary sojourners in the country. The highest ratio of admission from dysentery among European troops from 1870 downwards was 54·1, and the lowest 24·5; among native troops the highest was 96·3 and the lowest 39·3; among prisoners the highest was 113·3 and the lowest 79·4. On the other hand, the highest admission ratio from hepatitis among European troops in the same period was 58·1 and the lowest 18·1; the highest among native troops was 2·5 and the lowest 1·4; the highest among prisoners was 1·9 and the lowest 0·8. The dysentery of Europe is rarely followed by abscess of the liver. It is said that Roumania is the only European country where hepatic abscess is frequent as a complication of dysentery.

The report contains over 300 pages, with upwards of 200 more pages of annual returns and tables, and there remain quite a number of subjects and points on which we have not touched, but we have said sufficient to show that it is, in our opinion, an able official document, and that it affords a large amount of instructive and condensed information on a variety of subjects for those interested in the study of tropical medicine and hygiene.

THE HOLIDAY SEASON.

(*Continued from p. 1666.*)

THE LONDON AND NORTH-WESTERN RAILWAY COMPANY.—The inter-communication between the various railway companies in the British Isles makes it almost impossible to say exactly just where each line begins and ends, and the London and North-Western is no exception to the rule. The line from London communicates with Cambridge, Peterboro', Northampton, Rugby, Birmingham, Stafford, Crewe, Manchester, Leeds, York, Sunderland, Liverpool, and Newcastle; Glasgow, Edinburgh, Oban, Inverness, and Aberdeen; Dublin and Belfast, and various places in Wales. *Viâ* Dover, Folkestone, and Newhaven, the company issues through bookings to the Continent. Carlisle, the town which will this year be honoured by the presence of the British Medical Association is reached by this line, and no doubt excursions will be run during the time the meeting is in progress. The tourist programme, which embraces a comprehensive list of tours in England, Ireland, and Scotland, including the Lake District, North Wales, and the Isle of Man, is supplied gratis on application at the company's offices. The time-table gives particulars of the Continental routes.

THE GREAT WESTERN RAILWAY.—During the summer months this company will run cheap excursions to Bath, Bristol, Weston-super-Mare, Taunton, Ilfracombe, Exeter, Torquay, Plymouth, Falmouth, Penzance, Yeovil, Dorchester, Weymouth, Channel Islands, Shrewsbury, Welshpool, Barmouth, Aberystwyth, Ireland, and the Isle of Man. Visitors to any of these places will no doubt appreciate the list of seaside and country lodgings, boarding-houses, and hotels in districts served by this company, including Guernsey and Jersey.

THE SOUTH-EASTERN RAILWAY.—The programme of continental and local tourist and excursion arrangements giving particulars of special reduced fares and the list of farmhouses, hotels, and country lodgings in the districts served by this company is worth consulting.

SCOTLAND.

THE WEST HIGHLAND RAILWAY COMPANY.—Those who contemplate spending their holidays amidst the charming wild scenery of the West Highlands cannot do better than procure a copy of "Mountain, Moor, and Loch," a capital guide book to the district, illustrated with 230 original drawings and abounding in historical and literary allusions. The Highlands and Islands of Scotland include some of the most beautiful scenery in the world, and few places offer the advantages here presented for tourists. Grantown and Strathpeffer are both on this company's lines, the first

Digitized by Google

with a climate which is said to be beneficial in pulmonary complaints and the latter well-known for its medicinal springs. To describe the West Highlands of Scotland here is unnecessary, and full particulars as to train and fares can be obtained on application to the General Manager of the Highland Railway Company, Inverness. It may not be out of place, however, to give our readers the reason why, according to the author of "Mountain, Moor, and Loch," a lobster is known in the West Highlands as a "Banarie flea." The story runs that an American stopping in the Banarie Hotel made himself obnoxious by his contemptuous remarks on Scottish scenery. "Ben Nevis"? he said, "do you call that a mountain? You should see our mighty Rockies! Loch Linnhe? do you call that a lake! You should see our Lake Superior! Rannoch Moor? do you call that a plain? You should see our western prairies"! and continued in this strain to the intense exasperation of the Highland waiter who went and procured a live lobster which he secreted in the American's bed in requital of the insults. Hardly had the American gone to sleep when the lobster caught him by the toe, causing him to jump out of bed with a yell. "Boots" appearing on the scene, the American (rubbing his big toe as he spoke) thus solemnly addressed him: "Boots, you may not have such big mountains and big lakes and big plains here as we have in the States, but you have the most tarnation big fleas I ever experienced."

THE CALEDONIAN AND LONDON AND NORTH-WESTERN RAILWAY.—Summer tours in Scotland and England, published conjointly by these companies is an illustrated handbook containing descriptive notes of the chief points of interest on the journey to Scotland with itinerary of tours, fares, &c. A good map of England and Scotland accompanies the book, together with plans of Edinburgh and Glasgow.

NORTH BRITISH RAILWAY.—The tourist arrangements of this company embrace some interesting tours in Scotland.

IRELAND.

Considering the wild and bewitching nature of the scenery of the Emerald Isle it is passing strange that the Isle of Erin does not attract more visitors. The railway companies are, perhaps, not quite so smart as those in England, but slowness is an advantage sometimes, and the tourist in Ireland will be amply repaid for any inconvenience he may be put to in this direction.

THE GREAT NORTHERN RAILWAY OF IRELAND in their tourist and excursion programme publish a selection of tours from Dublin extending to Londonderry in the north, Belfast on the north-east, and Bundoran on the north-west coast. This latter place is reached by the ordinary rail service in five or six hours from Dublin, Belfast, or Londonderry, and is surrounded by the districts of Lough Erne, Donegal, and Sligo, the scenic charms of which are all well known. The Valley of the Boyne, too, with its historic associations, will well repay the visitor. Full information and interesting pamphlets describing various parts of the district covered by this railway can be obtained on application to the company's offices in Dublin.

THE GREAT SOUTHERN AND WESTERN RAILWAY.—The iron ways of this company intersect the southern portion of Ireland, extending through the far-famed Lake district of Killarney to Valentia Harbour. The time-table of the company details a list of tours which should suit the convenience of all, and a tastefully printed illustrated booklet describes the lakes and fjords of Kerry, which embrace scenery which the present Poet Laureate has fitly described as enchanting. A glance at the illustrations in the booklet will, however, do more to impress the reader with the beauty of the district than words could do.

THE CORK, BANDON, AND SOUTH COAST RAILWAY.—This company also issues an illustrated booklet describing the journey from Cork to Glengariff and Killarney known as the Prince of Wales route. In advising tourists to Ireland to write to the company for a copy of the pamphlet we need do no more than quote Thackeray, who has said, "Within five miles round the pretty inn of Glengariff there is a country of the magnificence of which no pen can give an idea."

WALES.

THE CAMBRIAN RAILWAYS.—"Picturesque Wales," price 6*d*., a handbook of scenery accessible from the Cambrian Railways, will repay a perusal even by those who have decided to spend their holidays elsewhere. It is well illustrated, and contains what many of the railway handbooks lack, a good index. For wild and picturesque scenery and legendary tales Wales has few equals, and the archæologist, the botanist, and the painter will all find ample material for study and recreation. Those, too, who revel in the mysteries of orthography can—and we say it with all due reverence—follow their favourite pursuit by inquiring into the meaning of such soul-stirring names as Cwm-Bychan, Cwmhir, Llanfihangel-geneu'r-glyn, Ynys-y-maengwyn, and others, whose "linked sweetness long drawn out" cannot but charm. The tourist, excursion, and seaside arrangements for the season give some exceptional facilities to visitors, and a feature of the Cambrian Railways is the issue of cheap weekly season-tickets, enabling the holder to travel by all trains and between all coast stations, including Machynlleth and Dolgelly. Over 1000 miles can thus be travelled for 15*s*. third-class or 25*s*. first-class. Express trains with first- and third-class lavatory carriages are run daily during the season in connexion with fast trains on the London and North-Western, Great Western, and other railways between London, Liverpool, Manchester, Birmingham, &c. The Cambrian Railways "Souvenir of Wild Wales." price 6*d*., containing fifty-five views, is a capital little publication. Time-tables, tourist programmes, guide books, and full particulars of trains, fares, &c., may be obtained at any of the company's stations or booking offices, and at Cambrian Office, Crue Woode Buildings, 17, Back Goree, Liverpool; on application to Messrs. Henry Gaze and Sons, Limited, Excursion Tourist Agents, Strand, London; or to the Passenger Superintendent, Oswestry.

(To be continued.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on the 11th inst., the President, Mr. CHRISTOPHER HEATH, being in the chair.

On the recommendation of the Committee of Management it was resolved (1) that the Forest School, Walthamstow, be added to the list of recognised places of instruction in chemistry, physics, and practical chemistry; and (2) that the East London Hospital for Children, Shadwell, be recognised as a place of study during the fifth year of the curriculum.

The Laboratories Committee presented a report on the work on diphtheria for the Metropolitan Asylums Board as follows: (*a*) Examination of material for diagnosis; since March 6th 3705 specimens have been examined and reported upon. The average number of specimens examined per diem has been 47·5. (*b*) The preparation of antitoxic serum; since March 6th the director has supplied 3910 doses of antitoxic serum for the treatment of diphtheria in the hospitals of the Metropolitan Asylums Board, and all the demands have been fully met. In addition to the number of doses sent out a considerable addition has been made to the reserve stock set aside to meet extra calls should they arise.

The Deputation Committee recommended that the deputations of Fellows and of Members be informed that as the Council had determined to take a poll of the Fellows on the question of the representation of the Members on the Council it was inexpedient to consider any other points involving alterations in the Charter of the College. The recommendation was adopted, and it was resolved to send similar replies to the movers and seconders of the resolutions carried at the annual meeting of Fellows and Members in November, and at the January meeting of the Fellows. A letter was read from Mr. H. P. Dunn forwarding a copy of a resolution adopted by the Committee of the Association of Fellows, suggesting the points which should be submitted to each Fellow on the question of the representation of Members of the College upon the Council. It was referred to the committee on the circular to the Fellows, and the Council authorised the committee to receive representations in writing in reference to the subject. It was resolved, on the suggestion of the Secretary, that the Calendar should be made up to Aug. 1st in each year in order that it might include the results of the elections to the Council in July. A letter was read from Mr. Reginald Harrison and Mr. John Langton reporting their attendance as the representatives of the College at the Congress of the Surgical Society of Germany.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are some of the principal amounts received at the Mansion House, the lists of which have been received at THE LANCET Office, up to the time of our going to press on Thursday, when the total amounted to nearly £17,000. The total sum recorded at the corresponding period last year was nearly £15,000:—

	£	s.	d.
St. Michael's, Chester-square (with additions)	1496	0	0
Christ Church, Lancaster-gate	1257	16	7
St. James's, West Hampstead	320	3	1
St. Nicholas, Chislehurst (including £100 from Mr. Richard Foster)	335	11	0
St. Michael's, Paddington	167	16	8
St. Andrew's, Wells-street	140	16	9
All Saints', Ennismore-gardens	502	4	0
Westminster Abbey	220	19	6
St. Alban's, Streatham	204	1	3
All Saints', Clapham-park	129	7	0
Union Chapel, Islington	112	0	0
Christ Church, Gipsy-hill	108	0	0
Holy Trinity, Roehampton	108	9	5
St. Paul's, Avenue-road	111	17	10
St. James's, Kidbrook...	120	3	8
St. Peter's, Brockley	120	0	0
St. Mark's, North Audley-street	102	9	0
Holy Trinity, Sydenham	206	13	0
St. Mary's, Bryanston-square	263	3	2
St. Columba's, Pont-street	121	0	0
Greek Church	104	14	0
St. Thomas's, Portman-square	114	9	0
St. John's Presbyterian Church, Kensington	126	5	0
Christ Church, Highbury	107	3	7
Holy Trinity, Tulse Hill	156	13	9
St. Paul's, Beckenham	163	13	7
St. Stephen's, South Dulwich	176	0	0
St. George's, Bickley	85	6	0
Holy Trinity, Marylebone	91	2	7
All Saints', Clapham-park	53	18	3
St. Saviour's, Clapham	29	7	1
St. James's, Garlickhithe	38	13	8
Islington Parish Church	20	0	0
St. Anne's, Wandsworth	28	9	5
St. Luke's, Berwick-street	34	1	5
Hornsey Parish Church	49	15	10
St. Mary's, Brookfield, N.W.	22	2	2
West Ham Parish Church	25	1	1
St. Saviour's, Southwark	26	12	2
Metropolitan Tabernacle	114	15	9
Holy Trinity, Eltham	57	17	3
St. John's, Redhill	40	1	1
St. Michael's, Paddington	167	16	7
The Chapel, Dulwich College	60	19	0

Northwood Church	28	4	5
Holy Trinity, Lyonsdown, New Barnet	26	8	1
Wesleyan Church, Holly Park, N.	27	5	0
St. Peter's, Norbiton	20	0	0
"Delta" (a further)	200	0	0
Guesdon Trustees	311	15	1
Legacy (John Smith)	500	0	0
Edward Chas. Healey, Esq.	105	0	0
"In Memoriam" (Crosby Lockwood)	20	0	0
St. Anne's, Soho	74	5	4
Miss Emily Old	25	0	0
St. John's, Clapham-rise (first instalment)	30	0	0
Old Malden Parish Church	91	10	9
St. Mary's Parish Church, Finchley	41	10	11
St. Andrew's, South Streatham	30	11	2
All Saints', Foot's Cray	26	1	0
St. Paul's Cathedral	249	0	6
Brixton Congregational Church	58	11	9
J. D'Arcy Hartley, Esq.	25	0	0
Colonel Sir Reginald Hanson, Bart., M.P., Alderman, &c. ...	10	10	0
St. Mary's (Old Church), Stoke Newington	35	1	6
St. Stephen's, Westminster	45	0	0
Christ Church, Chislehurst	58	8	7
St. Giles's (Parish Church), Camberwell	85	15	10
Christian Evidence Society (East London Branch)	55	0	0
F. F....	21	0	0
St. Mary Magdalen, Enfield	30	14	11
St. James's, Camberwell	30	5	0
St. Andrew's, Leytonstone	46	14	11
Westbourne-grove Presbyterian Church	82	0	7
Major Jones	20	0	0
Christ Church and St. Andrew's, Hornsey	74	0	7
Harrow Weald Church	27	10	10
St. Paul's, West Brixton	23	16	9

Other amounts have been received and will be published in our next issue.

THE ARMY MEDICAL STAFF.

THE annual dinner of the officers of the Army Medical Staff was held in the Whitehall Rooms of the Hôtel Métropole upon June 15th. The following officers and guests were present:—

Director-Generals: J. Jameson (in the chair), and Sir W. A. Mackinnon, K.C.B., Q.H.S.

Surgeon-Major-Generals: A. F. Bradshaw, C.B., Sir J. Fayrer, Bart., K.C.S.I., Q.H.P., A. H. Fraser, J. Inkson, E. C. Markey, C.B., J. B. C. Reade, C.B., Q.H.S., P. B. Smith, W. Taylor, W. A. Thomson, Q.H.P., J. J. Thompson, and W. M. Webb.

Surgeon-Colonels: M. Cogan, R. W. Clifton, W. G. Don, J. H. Hughes, Sir R. W. Jackson, Kt., C.B., J. H. Jeffcoat, G. McGrath, T. O'Farrell, W. S. Price, W. Riordan, W. Sly, H. R. L. Veale, and J. Watts.

Brigade-Surgeon-Lieutenant-Colonels: G. Andrew, J. M. Beamish, J. F. Beattie, A. L. Browne, A. F. S. Clarke, J. A. Clery, R. de la C. Corbett, D S.O., A. Doig, E. J. Fairland, W. J. Fawcett, E. Footner, M. M. Gallwey, J. Hector, J. W. Hulseberg, L. A. Irving, J. Johnston, M. Knox, J. G. Leask, C. Mackinnon, H. W. Mackinnon, D.S.O., W. H. Macnamara, A. Macrobin, J. W. Morgan, W. F. Ruttledge, W. F. Stevenson, F. P. Staples, W. Temple, V.C., T. Wright, and T. W. Wright.

Surgeon-Lieutenant-Colonels: W. B. Allin, F. E. Barrow, G. D. Bourke, W. Donovan, W. C. Gasteen, W. L. Gubbins, G. H. Le Mottee, N. McCreery, T. Ligertwood, and W. S. Pratt.

Surgeon-Majors: W. G. A. Bedford, U. J. Bourke, Sir J. R. A. Clark, Bart., A. E. Croly, A. Dodd, J. B. Emerson, R. F. D. Hackett, R. D. Hodson, J. W. Jones, H. C. Kirkpatrick, J. Maher, E. L. Maunsell, J. McGill, W. O'Sullivan, E. R. Power, G. W. Robinson, M. R. Ryan, and H. O. Trevor.

Surgeon-Captains: G. Cardew, T. H. F. Clarkson, H. A. Cummins, J. G. Deacon, H. P. Elkington, J. Fayrer, E. M. Hassard, H. St. G. S. Hore, R. W. H. Jackson, J. Moir, F. J. Morgan, D. M. O'Callaghan, R. J. Power, J. Ruxton, and R. J. Windle.

Guests present: Mr. Christopher Heath (President of the Royal College of Surgeons of England), Surgeon-Major-General W. R. Hooper, I.M.S., Brigade-Surgeon-Lieutenant-Colonel H. Smith (3rd Volunteer Battalion, Hampshire Regiment), Surgeon-Major W. Collingridge (Militia Medical Staff Corps), Dr. H. P. Cholmeley, Mr. E. Hart, and Mr. Vesey Holt.

Guests invited, but unavoidably absent: Dr. Wilks, President of the Royal College of Physicians, Sir James Dick, K.C.B., the Director-General of the Medical Department of the Royal Navy, Sir W. Guyer Hunter, K.C.M.G., Q.H.S., Volunteer Medical Staff Corps.

We are glad to see that the number of officers present showed an increase over last year, ninety-five as against seventy-five, and we trust next year to see an even larger

Digitized by Google

attendance. The arrangements were under the care of the hon. secretary to the dinner committee, Brigade-Surgeon-Lieutenant-Colonel Hector, to whom every credit is due, both for his excellent management and the untiring way in which he looked after the guests.

THE GENERAL MEDICAL COUNCIL:

THE RESIGNATION OF MR. WHEELHOUSE AND SIR WALTER FOSTER.

WE have received for publication the following letter addressed by Mr. Wheelhouse and Sir Walter Foster to the profession announcing their intention of not offering themselves for re-election at the expiration of their term of office on the Council in November next:—

TO THE MEMBERS OF THE PROFESSION IN ENGLAND AND WALES.

GENTLEMEN,—Ten years ago, after a struggle of many years' duration, Parliament conceded the boon of Direct Representation of the Profession on the General Medical Council, and you did us the honour to elect us as your first representatives. During those ten years we have endeavoured to serve you to the best of our ability, and have never lost sight of your true interests. We are not without the hope that we have been of service both to you and to the Council—to you, by acting as your exponents in the various questions of professional importance that have from time to time been brought under the notice of the Council, and to the Council by seeking temperately to place your views before it and, as far as possible, to assist in carrying out its general work. In what we have succeeded and in what we have failed we are content to leave the history of the Council to determine; but, so far as your wishes have been compatible with the Acts of Parliament which it is the duty of the Council to administer we have never lost sight of them or failed to advocate them to the utmost of our power.

The time has now come when, for the third time, you are called upon to choose your representatives, and, after careful and anxious consideration, we have determined to ask you to release us from the responsibility of the office. We desire most cordially to thank you for the great honour you have conferred upon us by twice entrusting us with your interests, and also to place on record our grateful sense of all the kindness we have personally received at the hands of every member of the Council, and especially of the various presidents under whom it has been our privilege to serve.

In conclusion, we would urge you to make very deliberate and careful choice of your future representatives, remembering the high order of the duties the Council is called upon to exercise, and when you have elected them to give them that moral support without which it is impossible for them efficiently to represent you.

We are, gentlemen, your obedient servants,

C. G. WHEELHOUSE.
B. WALTER FOSTER.

June 12th, 1896.

THE CROYDON BOROUGH HOSPITAL, WADDON.

THE new buildings of the Croydon Borough Hospital were opened on Saturday, June 6th, and the municipality is to be congratulated on possessing a permanent isolation hospital of the most approved type. The triangular site on which the pavilions have been erected comprises eight acres of land moderately elevated and situated some two miles from the more populous portions of the district. Accommodation is provided for 116 patients. We have not space to describe in detail the various wards and administrative blocks which constitute the hospital, but there are one or two points specially worthy of notice to which we may refer. In the first place everything has been done to make the wards as comfortable and attractive as possible in order that patients requiring isolation may be induced to take advantage of the accommodation provided by the borough. With the same object in view a private block has been built for people of means consisting of four wards containing six beds. Each ward is aerially disconnected, so that more than one class of infectious disease can be treated at the same time. The interior furnishing has been carried out in the best possible style consistent with a sick chamber. Dr. Leonard Wilde, the visiting physician, who has superintended the internal arrangements of the buildings, has introduced a novel feature with regard to the clothing of the patients. On admission to hospital each patient is provided with a garment the colour of which indicates the nature of the disease from which he or she may be suffering. For instance, scarlet fever patients are clothed in pink or red, diphtheria patients in blue, and enteric fever patients in yellow. By this means the variously infected garments are readily distinguished for cleansing purposes, and as a day is set apart for each colour to be washed there is no danger of one set of garments becoming infected with the germs that may be contained in another set. The additional precaution of disinfecting the clothes before entering the washhouse is, of course, taken. Another desirable feature of the new hospital, which has been carried out by Dr. Wilde, is the bacteriological research laboratory. Besides the use which can be made of this department should a doubtful case present itself at the hospital, it is at the disposal of any medical practitioner who may wish to assure himself of the exact nature of a case coming under his notice. On application a culture outfit is forwarded to the medical man, who makes the culture and returns the tube in its case, and within twenty-four hours he receives a report from the hospital.

THE LATE DR. CHARLES RUMNEY ILLINGWORTH.

SOME of the friends of the late Dr. C. R. Illingworth have started a fund on behalf of his widow and children, the first list of subscriptions to which we have much pleasure in subjoining. Dr. Illingworth's early death under distressing circumstances deprived the profession of an ardent votary of the science of medicine, and we confidently recommend the case of his wife and children to the generous consideration of others who did not know him personally, and who will perhaps take our assurance that the money is sadly all wanted, and the case a thoroughly deserving one for benevolence.

HEALTH EFFICIENCY OF THE ENGLISH, FRENCH, ITALIAN, AND RUSSIAN ARMIES.

AT this moment, when the nation is called upon to make great sacrifices so as to increase our means of defence, all that concerns the efficiency of the army and navy is of more than usual importance and interest. It need scarcely be said that it does not suffice to enroll soldiers and sailors, but care must be taken to preserve them in sound bodily strength and health. In respect to general sanitation we may justly claim that the care taken of the health of the army and navy of Great Britain will compare favourably with the best organised

Digitized by Google

forces of any foreign country. In one important phase of the question, however, we stand at a great disadvantage. The fighting efficiency of our land and sea forces is very considerably impaired by the prevalence of venereal disease among officers and men. Dr. O. Commenge, in a work recently published in Paris entitled "Les Maladies Vénériennes dans les Armées Anglaise, Française, et Russe," points this out in a very conclusive manner. Dr. Commenge states that the proportion of soldiers who during the four years 1889 to 1892 suffered from venereal disease in what he describes as the English army of the metropolis amounted to 217·1, 212·4, 197·4, and 201·2 per 1000. Thus it may be said in round numbers that one-fifth of the troops of the British army are incapacitated for service during the course of the year and this solely through contracting some form of venereal disease. Judging from our own investigations at Aldershot and elsewhere we may conclude that the case is not overdrawn. The figures vary somewhat, but, roughly speaking, a fifth is certainly no exaggeration, for at Aldershot we found that the proportion of soldiers suffering from venereal disease during the year was equal to a quarter of the entire force. The importance of these calculations will at once be understood when compared with similar figures given for the French and Russian armies. For France we find that during the four years in question the prevalence of venereal disease in the army was equal to 45 8, 43·8, 43·7, and 40 0 per 1000 soldiers. For Russia the figures are 40·7, 43·0, 41·5, and 44 6 per 1000 soldiers. Thus it will be seen that venereal disease is four or five times more prevalent in the English than in the French or Russian armies. For one French or Russian soldier who is incapacitated from service because he is suffering from venereal disease there are four or five English soldiers similarly incapacitated. Putting every other consideration aside, surely, as a mere matter of military defence, this is an evil that should not be neglected.

In dealing with the Contagious Diseases Act it has been shown that there is not to-day more venereal disease prevalent in the British Army than there was previously to the abolition of the Act, and there are figures that seem to confirm this theory. But we have, in answer, pointed out that the tone of the army has greatly improved, that a higher class of men now serve in the ranks, that great cleanliness is observed by both the men and the women, and that there is a more general use of antiseptics and a more widespread knowledge of the precautions that can be taken. All this has contributed to prevent matters being worse than they are, but surely they are bad enough. The argument that the Contagious Diseases Acts were of no use because the statistics of to-day show no very marked increase in the prevalence of venereal diseases as compared with what existed many years ago when the Act was in force loses all its significance when we put the British army by the side of the armies of France and Russia. In those countries the Contagious Diseases Act, or its equivalent, is in full operation, and we see by the figures given the enormous advantage that has resulted. But, just as we argue that matters would be even worse than they actually are in England had not the general tone and education of the army improved of late years, so it may be urged that the general tone of the continental armies is much superior to that of the English army. It may be maintained, with some semblance of reason, that if there is so little venereal disease in the French army it is because everybody must be a soldier and serve in the ranks; therefore, the whole social tone of the army is much higher, since men of elevated rank and the best education are to be found serving as common soldiers. Apart from the very doubtful question as to whether men of high rank are much more moral than men of low rank, these arguments as to the high social tone of the French rank-and-file certainly do not apply to the Russian rank-and-file, and we find that if there is any difference there is even less venereal disease in the Russian than in the French army. If we take an average of the four years mentioned above the prevalence of venereal disease among the English troops amounted to 207 per 1000 per annum, among the French soldiers to 44·3 per 1000, and among the Russians to 42·4 per 1000. Thus it cannot be said that it is the high social tone of the French army that reduces the proportion of venereal disease, for we have still less venereal disease among the unlettered peasants who in the main constitute the Russian army.

But to those persons who, by all manner of ingenious and roundabout arguments, try to prove that the Contagious Diseases Acts can do no good we may oppose the still more significative experience acquired in the Italian army. There the law which enforced the medical examination of women was abrogated. The prevalence of venereal disease in the Italian army was about the same as in the French and Russian armies. It varied from 4 to 5 per cent. per annum. No sooner was the law abolished than the prevalence increased and in a short time 10 per cent. of the troops contracted venereal disease in the course of a year. After three years of trial the Italian Government reversed its former decision and the law regulating prostitution was re-established. This is far more conclusive than any argument that can be derived from the experience acquired in England. As the English law was only enforced in a few towns it was very defective in its operation, and it is not surprising if its abolition failed to produce any very marked change. In Italy, as in all other continental countries, the law did not apply merely to garrison towns but to the entire country. It, therefore, did produce very great and beneficent results, as is shown by the fact that the prevalence of venereal disease was simply doubled when the law was abolished, and that after only three years of experience the Government and the country were glad to return to the old and successful methods of dealing with this dread disease. As for England, we have argued the question so often and from so many points of view that we do not propose to again travel over the well-worn ground on this occasion. We are simply anxious, at a moment when the public mind is preoccupied with the question of military armaments, to point out that one of the most practical means of increasing the fighting strength of both army and navy would be to protect our soldiers and sailors from venereal disease in the same manner as the armies and navies of continental countries are protected.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the committee of the Association of Fellows of the Royal College of Surgeons of England was held on the 10th inst. at 25, Grosvenor-street, W., Mr. George Pollock, President, being in the chair. The minutes of the last meeting were read and confirmed.

Mr. H. Percy Dunn, the honorary secretary, reported that he had received a letter from Mr. Victor Horsley in reply to the invitation of the committee that he should come forward in the interests of the Association as a candidate for a seat on the Council of the College at the forthcoming election. Mr. Victor Horsley replied in effect that the very nature of the request made it difficult for him to refuse, but he was so deeply committed to the furtherance and establishment of the principles of medical defence that he could not venture to accept fresh and what would unquestionably be grave responsibilities, and he hoped that the committee would accept his very grateful thanks for their confidence and kindness, understanding that it was only other professional work which rendered him unable to serve, as he should greatly like to do, the objects of the Association. Mr. Percy Dunn further reported that in accordance with the instructions of the committee he had communicated with the provincial Fellow whose name had been brought forward as a possible candidate to represent the Association at the College election and that a reply had been received from him to the effect that he would be willing to come forward if nominated by the Association.

At this stage a member of the committee mentioned that he had just heard that the President of the Association, Mr. George Pollock, had intimated to Mr. Holmes that if it were the desire of the committee that he should stand he would willingly do so.

On the motion of Dr. Robert Barnes and Mr. Gant it was unanimously agreed that the offer of Mr. Pollock should be accepted, and as it was felt to be undesirable to bring forward another candidate Mr. Percy Dunn was asked to communicate with the provincial Fellow above referred to upon this subject.

It was reported to the committee that Mr. Clement Lucas of Guy's Hospital was a candidate for the Council, and that in reply to certain questions addressed to him by Mr. Norton he had expressed views almost entirely in unison with those

Digitized by Google

advocated by the Association. The hope was therefore expressed that Mr. Clement Lucas would be successful in securing one of the vacant seats; especially as with the exception of Mr. Pollock he was the only candidate who was known to have stated his intention to support a reforming policy including the resolution passed in favour of giving direct representation to the Members of the College by so large a majority of the Fellows at the last half-yearly meeting of Fellows held in January. It was decided to send a circular to the members of the Association in reference to the approaching elections.

A notice of motion which Mr. Holmes intended to send to the secretary of the College for the meeting of the Fellows in July was read. The terms of the motion are the following: "That the Council be requested to instruct its representative on the General Medical Council to forward in every way which seems feasible the objects of the Civil Rights Defence Committee in the case of Mr. R. B. Anderson."

A resolution was passed instructing the honorary secretary to ask Mr. Victor Horsley to second the motion of Mr. Holmes, and if he was unable to do so to secure the services of Mr. George Jackson of Plymouth for that purpose.

It was decided to hold another meeting of the committee before the election on July 2nd, and there being no other business the committee adjourned.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Pollution of the River Dee and its Tributaries, by Dr. BRUCE LOW.[1]—This is one of the most comprehensive reports which have been issued by the Medical Department of the Local Government Board on the question of river pollution, and it has the more interest and importance because the Dee forms in its lower reaches the water-supply for the city of Chester and because a Bill is now before Parliament for the erection of a dam across the river below Chester which, it is contended, will go materially to diminish the pollution to which the river is alleged to be subjected at the point of the water intake. For the moment, however, it will be convenient to refer to the pollutions that take place above the water intake. The Dee has its origin in the overflow waters of Bala Lake, and, receiving a number of tributaries, it flows on for some ninety miles to the sea. In this course it touches on five separate counties and with its affluents comes into relation with no less than twenty-one sanitary districts within the watershed of the river. A description of these numerous districts is given by Dr. Low in special relation with their influence on the water of the Dee, and the detailed attention given to this subject may be judged of when it is stated that the report covers no less than forty-five folio pages of printed matter, together with plates and illustrations. Anything more disturbing to the consumers of the Dee water can hardly be conceived, for the sewage and other filth, including manufacturing refuse, of nearly the entire area find their way untreated into the main river or its branches. Llangollen is a gross offender, and photographic plates are inserted in the report to show how sewer outfalls, watercloset soil-pipes, privies, &c., all open out directly into the bed of the river, the filth to be washed down in the direction of Chester at the next flush. Summarising this description of Llangollen Dr. Low says: "In a word, the liquid and solid excrement of nearly the entire population of Llangollen goes at once to the Dee"; and he recalls the fact that though the normal population of the place may not exceed 3000 it must be some 5000 at least when in the summer months the lodging-houses and the hotels are full of visitors. Indeed, the story which Dr. Low sets out from the beginnings of the streams until within a comparatively small distance of the point where the intake of the Chester Waterworks Company is placed is, as he pithily and forcibly puts it, an "almost endless catalogue of contaminations of the Dee and its affluents by the excrement of men and animals, by trade processes, and by other impurities." And he adds that amongst the principal offenders against the law in this matter are many authorities who are entrusted by the Legislature with the maintenance of public health. But this is not all. Chester itself grossly pollutes the river by its sewage effluent and otherwise below the city and the water intakes, some of the stuff being spoken of as a torrent of foul sewage, black as ink, suddenly forced into and blackening the river nearly half-way across. And the position of these pollutions below the point of intake unfortunately affords no safety, for at spring tides the water running in at the mouth of the river overtops the Dee weir from one to six feet, carrying with it filth, dead dogs, &c., and the tidal influence is felt as far as twelve miles above Chester. Some have contended that owing to the flow of fresh water from above—i.e., the water polluted as we have described—no returning filth can get up to the intakes; but a great effort is now being made to get Parliamentary powers to prevent this very pollution from below by the erection of another weir. It is to be hoped this action indicates that the authorities are now more alive to the necessities of the case than they were in 1892, when, on Dr. Ballard's report, a committee of the corporation decided that the water was of a "high standard of excellence," and yet in the same breath urged that power should be procured to stay the pollutions. But no stoppage of filth from below will get rid of the almost endless catalogue of pollutions from above, and no trust should be placed on mere filtration when the source of the supply is fouled with such a bulk of excremental and other filth as is here in question.

On the Sanitary Circumstances and Administration of Cowbridge, by Dr. BRUCE LOW.—This inquiry was instituted on a complaint by the Glamorganshire County Council to the effect that the corporation had not properly enforced the provisions of the Public Health Act. Cowbridge is little more than a village, but unhappily it is a separate entity for public health purposes by reason of its being a borough. The population at the last census was only 1377, occupying 263 houses, and it was more than usually populous at the time owing to an influx of railway navvies. The public water-supply is from six sources. One seems good and wholesome, a second may be so, but the four others vary from being derived from wells sunk close to cesspits or burial grounds down to supplies that are actually offensive to the nose and to taste. Private wells hardly differ from the public ones as to risk of pollution. With respect to sewerage Dr. Low reports that there is no proper system, that the town ditch receives the contents of highway drains which have been turned into sewers, and that cesspools soak into the surrounding soil, which is thereby greatly polluted. Privies and cesspits with overflows add to the mischief; or, where near the river bank, empty directly into the stream. A few earth-closets, however, have been provided. There is no public scavenging and some gross accumulations of refuse result. The slaughter-houses and most of the common lodging-houses are unsatisfactory, and by-laws are in some respects not enforced. House accommodation is in many respects bad, and formerly it was reported that much of the "wretched house property" belonged directly or indirectly to town councillors, a statement now quoted by Dr. Low. Money has been spent in the little town, but it has not been devoted to its most pressing needs; indeed, after discussing the administration and past history of the place in connexion with the present faulty conditions Dr. Low arrives definitely at the conclusion that the contention of the county council has been made out, and that the town council have been especially neglectful in not providing a proper water-supply and sewerage for their district. No other conclusion was possible; indeed, the difficulty is rather to detect what sanitary functions have been carried out by this authority.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6571 births and 3473 deaths were registered during the week ending June 13th. The annual rate of mortality in these towns, which had been 17·6 and 17·8 per 1000 in the two preceding weeks, declined again last week to 16·7. In London the rate was 16·5 per 1000, while it averaged 16·9 in the thirty-two provincial towns. The lowest rates in these towns were

9·1 in Norwich, 11·3 in Derby, 12·1 in Plymouth, and 12·6 in Leicester; the highest rates were 20·4 in Oldham, 21·2 in Sunderland, 21·7 in Bolton, and 24·3 in Manchester. The 3473 deaths included 541 which were referred to the principal zymotic diseases, against 540 and 559 in the two preceding weeks; of these, 221 resulted from measles, 117 from whooping-cough, 69 from diphtheria, 65 from diarrhœa, 39 from scarlet fever, and 30 from "fever" (principally enteric). No fatal case of any of these diseases was recorded in Swansea; in the other towns they caused the lowest death-rates in Huddersfield, Bradford, Brighton, and Birmingham; and the highest rates in Salford, Halifax, Burnley, Manchester, and Hull. The greatest mortality from measles occurred in Croydon, Bristol, Manchester, Hull, and Gateshead; from whooping-cough in Cardiff, Burnley, Salford, Hull, and Halifax; from "fever" in Wolverhampton; and from diarrhœa in Leicester. The mortality from scarlet fever showed no marked excess in any of the large towns. The 69 deaths from diphtheria included 49 in London, 5 in Birmingham, 2 in Liverpool, and 2 in Leicester. No fatal case of small-pox was registered in any of the thirty-three large towns. There were 27 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 13th inst., against 22, 19, and 25 at the end of the three preceding weeks; 9 new cases were admitted during the week, against 5, 3, and 8 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2781, against numbers increasing from 2523 to 2717 on the six preceding Saturdays; 352 new cases were admitted during the week, against 305, 297, and 318 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 230 and 213 in the two preceding weeks, further declined to 183 last week, and were 53 below the corrected average. The causes of 55, or 1·6 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Oldham, Blackburn, Newcastle-upon-Tyne, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 19·2 per 1000 in each of the three preceding weeks, declined again to 18·5 during the week ending June 13th, but exceeded by 1·8 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 12·0 in Perth and 14·7 in Edinburgh to 18·4 in Aberdeen and 21·2 in Glasgow. The 539 deaths in these towns included 23 which were referred to whooping-cough, 21 to measles, 16 to diarrhœa, 4 to scarlet fever, 4 to "fever," and 1 to diphtheria. In all, 69 deaths resulted from these principal zymotic diseases, against 83 and 81 in the two preceding weeks. These 69 deaths were equal to an annual rate of 2·4 per 1000, which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had declined from 38 to 26 in the four preceding weeks, further fell to 23 last week, of which 17 occurred in Glasgow and 4 in Paisley. The deaths from measles, which had been 20 and 25 in the two preceding weeks, declined again to 21 last week, and included 20 in Glasgow. The 4 deaths referred to different forms of "fever," corresponded with the number in the preceding week, and were all recorded in Glasgow. The fatal cases of scarlet fever, which had increased from 3 to 8 in the four preceding weeks, declined to 4 last week, and included 2 in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 97 and 93 in the two preceding weeks, further declined to 82 last week, and were slightly below the number in the corresponding week of last year. The causes of 32, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·9 and 19·8 per 1000 in the two preceding weeks, rose again to 23·7 during the week ending June 13th. During the past eleven weeks of the current quarter the death-rate in the city has averaged 23·1 per 1000, the rate during the same period being 18·1 in London and 16·9 in Edinburgh. The 159 deaths registered in Dublin showed an increase of 26 upon the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 9 and 8 in the two preceding weeks; of these, 4 resulted from whooping-cough, 3 from scarlet fever, 2 from "fever," 1 from diarrhœa, and not one either from small-pox, measles, or diphtheria. These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 3·1 in London and 0·9 in Edinburgh. The 4 fatal cases of whooping-cough exceeded the number recorded in any week during the current year. The 3 deaths from scarlet fever showed a further increase upon recent weekly numbers, while the mortality from diarrhœa showed a decline. The deaths referred to different forms of "fever," which had been 5 and 3 in the two preceding weeks, further fell to 2 last week. The 159 deaths in Dublin last week included 31 of infants under one year of age, and 36 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded the numbers recorded in the preceding week. Two inquest cases and 2 deaths from violence were registered; and 54, or more than a third, of the deaths occurred in public institutions. The causes of 7, or more than 4 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING MAY, 1896.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during May in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 9·2 per 1000 of the estimated population. In the three preceding months the rates had been 8·8, 8·4, and 7·5 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Westminster, St. James Westminster, Hampstead, Strand, St. Saviour Southwark, St. George Southwark, and Woolwich; while they showed the largest excess in St. Luke, Bethnal Green, St. George-in-the-East, Poplar, St. Olave Southwark, Greenwich, and Plumstead. The prevalence of small-pox in London during May showed a further decline from that recorded in recent months, only 12 cases being notified, including 2 in Kensington, 2 in Islington, and 2 in Bethnal Green sanitary areas. The Metropolitan Asylum Hospitals contained 15 small-pox patients at the end of May, against 45, 33, and 10 at the end of the three preceding months; the weekly admissions averaged 4, against 6, 7, and 4 in the three preceding months. The prevalence of scarlet fever in London showed a marked increase during May; this disease was proportionally most prevalent in Marylebone, Hackney, City of London, Bethnal Green, St. George-in-the-East, Limehouse, Battersea, and Plumstead sanitary areas. The Metropolitan Asylum Hospitals contained 2614 scarlet fever patients at the end of May, against 2867, 2688, and 2464 at the end of the three preceding months; the weekly admissions averaged 273, against 258, 234, and 208 in the three preceding months. The prevalence of diphtheria in London during May showed an increase upon that recorded in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in Clerkenwell, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, Camberwell, Greenwich, and Lewisham. There were 703 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of May, against 715, 704, and 713 at the end the three preceding months; the weekly admissions averaged 95, against 99 and 89 in the two preceding months. The prevalence of enteric fever in London showed a slight decline from that recorded in the preceding month; this disease was proportionally most prevalent in Hampstead, Clerkenwell, Newington, and Bermondsey sanitary areas. Erysipelas was proportionally most prevalent in Holborn, St. Luke, Bethnal Green, Whitechapel, and Poplar sanitary areas. The 16 cases of puerperal fever notified during May included 5 in Islington, 2 in Poplar, and 2 in Lambeth sanitary areas.

Digitized by Google

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the different sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, May 30th, the deaths of 5837 persons belonging to London were registered, equal to an annual rate of 17·2 per 1000, against 20·0, 19·4, and 18·7 in the three preceding months. The lowest death-rates during May in the various sanitary areas were 9·5 in Hampstead, 11·2 in St. George Hanover-square, 12·2 in Lee, 13·7 in Hammersmith, 14·1 in Paddington, 14·2 in Fulham, and 14·3 in St. James Westminster; the highest rates were 21·6 in Holborn, 21·8 in Limehouse, 22·3 in St. George-in-the-East, 23·3 in St. Luke, 24·5 in St. Martin-in-the-Fields, 24·7 in St. Saviour Southwark and in Woolwich, and 27·8 in Strand. During the four weeks of May 1121 deaths were referred to the principal zymotic diseases in London; of these, 464 resulted from measles, 354 from whooping-cough, 179 from diphtheria, 58 from scarlet fever, 42 from diarrhœa, 24 from enteric fever, and not one from small-pox. These 1121 deaths were equal to an annual rate of 3·3 per 1000; among the various sanitary areas the lowest death-rates from these diseases were recorded in Hammersmith, St. George Hanover-square, St. James Westminster, Hampstead, and City of London, and the highest rates in Chelsea, St. Martin-in-the-Fields, Strand, Bethnal Green, Battersea, Woolwich, and Plumstead. The 464 deaths referred to measles were 176 above the corrected average number in the corresponding periods of the ten preceding years; among the various sanitary areas this disease showed the highest proportional fatality in Kensington, Chelsea, St. Giles, St. Martin-in-the-Fields, Strand, Battersea, Woolwich, and Plumstead. The 58 fatal cases of scarlet fever were within 4 of the corrected average number; the mortality from this disease showed no marked excess in any of the sanitary areas. The 179 deaths from diphtheria were 56 above the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Chelsea, Marylebone, St. Martin-in-the-Felds, Bethnal Green, Limehouse, Mile End Old Town, Camberwell, Greenwich, and Plumstead. The 354 fatal cases of whooping-cough were as many as 126 above the corrected average number; this disease showed the highest proportional fatality in Stoke Newington, Holborn, Bethnal Green, Limehouse, Bermondsey, Rotherhithe, Battersea, and Wandsworth sanitary areas. The 24 deaths referred to enteric fever were 11 below the corrected average number; there was no marked excess of enteric fever mortality in any of the sanitary areas. The 42 fatal cases of diarrhœa were 17 below the corrected average number. In conclusion, it may be stated that the mortality in London during May from these principal zymotic diseases were nearly 40 per cent. above the average.

Infant mortality in London during May, measured by the proportion of deaths under one year of age to births registered, was equal to 132 per 1000. Among the various sanitary areas the lowest rates of infant mortality were recorded in Paddington, St. George Hanover-square, Hampstead, Stoke Newington, Whitechapel, and Mile End Old Town; and the highest rates in Kensington, St. James Westminster, St. Giles, St. Martin-in-the-Fields, Strand, City of London, and Woolwich.

THE SERVICES.

ARMY MEDICAL STAFF.

Surgeon-Lieutenant John Herbert Whitehead resigns his commission.

INDIA AND THE INDIAN MEDICAL SERVICES.

Brigade-Surgeon-Lieutenant-Colonel G. Hutcheson, M.D., re-appointed to be Sanitary Commissioner, North-Western Provinces and Oudh. The following promotions are made in the Madras Medical Establishment:—Surgeon-Lieutenant-Colonels to be Brigade-Surgeon-Lieutenant-Colonels: W. E. Johnson, M.D., vice Brigade-Surgeon-Lieutenant-Colonel T. J. McGann, promoted; G. F. Bevan, vice Brigade-Surgeon-Lieutenant-Colonel A. L. Hackett, who has retired; A. F. Dobson, M.B., vice Brigade-Surgeon-Lieutenant-Colonel P. R. Martin, who has retired; C. Little, M.D., vice Brigade-Surgeon-Lieutenant-Colonel J. F. Sargent, deceased; A. N. Rogers Harrison, vice Brigade-Surgeon-Lieutenant-Colonel W. Price, M.D., who has retired.

NAVAL MEDICAL SERVICE.

Deputy Inspector-General of Hospitals and Fleets Alexander Turnbull, M.D., has been promoted to the rank of Inspector-General of Hospitals and Fleets in Her Majesty's Fleet. Fleet-Surgeon Richard William Coppinger, M.D., has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet. The following appointments are announced. Deputy Inspectors-General of Hospitals and Fleets: H. Macdonnell to Chatham Hospital; R. W. Coppinger to Haslar Hospital; J. H. Martin, D.S.O., to Malta Hospital. Fleet-Surgeon T. D. Gimlette to Haslar Hospital. Staff-Surgeon S. W. Vasey to the *Caledonia*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Josiah Telfer Thomas, 1st Volunteer Battalion the Duke of Cornwall's Light Infantry, to be Surgeon-Captain.

VOLUNTEER CORPS.

Rifle: 3rd Volunteer Battalion the Northumberland Fusiliers: William George Richardson, M.B., to be Surgeon-Lieutenant. 2nd (Prince of Wales's) Volunteer Battalion the Devonshire Regiment: John Harley Gough, gent., to be Surgeon-Lieutenant. 1st Volunteer Battalion the Leicestershire Regiment: William Pemberton Peake, gent., to be Surgeon-Lieutenant. 1st Volunteer Battalion the Royal Welsh Fusiliers: John Edward Henry Davies, gent., to be Surgeon-Lieutenant. 5th Volunteer Battalion the Cameronians (Scottish Rifles): Surgeon-Captain H. Arthur, M.D., to be Surgeon-Major. 1st Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment): Lieutenant R. H. Luce, M.B., from the 2nd Volunteer Battalion the Wiltshire Regiment, to be Surgeon-Lieutenant.

DEATHS IN THE SERVICES.

Fleet-Surgeon William Gordon James Ayre, R.N. (retired), at Cheltenham on the 9th inst., in his seventieth year. He was appointed a Surgeon in the Navy in 1851, and was Assistant-surgeon of the *Penelope* on the West Coast of Africa. He served in the *Recruit* during the Russian War in the Black Sea, 1855, and was present at the expedition to Keitch and the operations in the Sea of Azov (Crimean and Turkish medals and clasp for Azov).

VOLUNTEER MEDICAL ASSOCIATION AMBULANCE CHALLENGE SHIELD.

The sub-committee appointed by the council of the association have decided that the annual competition for the shield shall take place on Saturday, July 18th. The competition will be held at Wellington Barracks, by kind permission of the officer commanding, and squads intending to compete must be on the ground at four o'clock. The annual mess dinner of the Volunteer medical officers will take place at Limmer's Hotel at 7.30 on the same evening. Further particulars can be obtained on application to the honorary secretaries, 20, Hanover-square, London, W.

THE SOUDAN CAMPAIGN.

There is reason to believe that the highly successful attacks that have been recently made upon the Dervishes and the capture of Firket, followed by the taking of Suarda, will have far-reaching results. The Anglo-Egyptian force continues to enjoy good health. At Wady Halfa the sick recently numbered only 5·6 per cent. The hospitals are working very satisfactorily. The wounded and the prisoners captured from the Dervish force are well cared for.

JAPANESE LOSSES IN FORMOSA.

The following statistics, published in several Japanese newspapers, are apparently derived from official sources:—From May 26th to Nov. 15th, 1895, the average strength of the Japanese Army of occupation in Formosa was 95,000 of all ranks; killed in action, or died from wounds during the period, 195; died from disease in the various hospitals, 4447; invalided, 21,748; remaining under treatment, 5246; discharged to duty, 7162.

THE GARRISON IN EGYPT.

We are very glad to learn that the British troops in Egypt have not suffered from the cholera epidemic that has recently prevailed in Alexandria, Cairo, and other places. One fatal attack occurred in the person of a soldier stationed at the

Digitized by Google

citadel in Cairo, but no other cases have since arisen among the troops. Their health is stated to be excellent.

Deputy-Surgeon-General G. S. Ryerson, M.D., Canadian Militia, Toronto, who has recently been through a course at the Volunteer Ambulance School of Instruction, obtained a certificate of proficiency at an examination held before a special board of Army medical officers on June 2nd at the Station Hospital, Rochester-row, S.W.

The Rev. Sir Borradaile Savory, Bart., M.A., son of the late Sir William Savory, has accepted the acting chaplaincy to the Volunteer Medical Staff Corps (the London companies).

Surgeon-Lieutenant-Colonel W. Campbell, of the Grenadier Guards, has been again selected for the post of Principal Medical Officer at the Bisley Rifle meeting.

The Hampshire Militia Medical Staff Corps will be encamped at the Royal Victoria Hospital, Netley, from the 3rd to 29th prox.

Correspondence.

"Audi alteram partem."

"ISOLATION AND THE PUBLIC HEALTH ACT."

To the Editors of THE LANCET.

SIRS,—Dr. Benham, in your issue of the 13th inst., calls attention to the important subject of isolation in infectious diseases. No two opinions can exist as to the importance of early diagnosis and the wisdom of removal to an isolation hospital of cases of small-pox and typhus fever; yet in cases of scarlet fever, diphtheria, and enteric fever something may be said against indiscriminate removal. I believe the practice of removal to hospital after the receipt of the notification certificate differs almost in every district according to the opinions held by the medical officer of health or sanitary authority. I know that some medical officers of health believe that every case of infectious disease should be removed to hospital for isolation and treatment, so that I am pleased that Dr. Benham has received a reply from the Local Government Board which leaves one to imply that the consent of the medical attendant should be sought before removal. The Notification Act, 1889, was not passed for the purpose of enabling the sanitary authority to effect removal of *all* cases but to enable the medical officer of health to early become acquainted with outbreaks of epidemic disease. As an old sanitarian and a general practitioner but a young medical officer of health, I agree with many of Dr. Benham's reasons for allowing the treatment of infectious cases such as scarlet fever and diphtheria at home, although I do not believe that patients are longer in recovering when taken to hospital or that they have a better chance of recovery when left at home, and I cannot subscribe to the statement that it is an easy matter to isolate cases of scarlet fever or diphtheria completely in an ordinary dwelling house; but I do believe it can be done sufficiently, and this meets the requirements of the case. I have had as a private practitioner my own little "grievances" in reference to the removal of cases, and now as a medical officer of health have to do my duty and prevent the spread of infectious diseases among the ratepayers. Now unless my fellow practitioners give me a loyal support I cannot hope to do this. A short experience which I will relate I have every reason to be satisfied with, and as my sanitary committee are desirous of keeping down the expenses of the infectious disease hospital from a ratepayer's point of view I must do what I can to encourage my medical brethren to treat as many cases as they can outside, providing sufficient isolation is possible, only removing such cases as they request. When I took office small-pox and typhus fever were rampant, and scarlet fever was prevalent in different parts of the town. I called my *confrères* together and laid down a line of action which I intended to follow—namely, to take into hospital only cases of small-pox and typhus fever, and till these no longer occured other infectious cases would require to be treated at their own homes, and I trusted my *confrères* would assist me, especially in regard to isolation in the patient's own homes. Expressions of opinion were given, and some thought isolation in a cottage impossible, but all agreed to assist me as far as they could. I was willing to see all doubtful cases of typhus fever or small-pox with them and to ensure early removal. One of my sanitary inspectors was given the extra duty of visiting periodically and systematically all houses in which scarlet fever was present in order to see that everything was being carried out as far as could be under the circumstances, and supplying an abundance of disinfectants. In four months I was enabled to report to my committee that small-pox was stamped out and typhus fever had disappeared, scarlet fever being kept within bounds. The only cases of infection spreading was in the same house, just as we have had since even after early removal to hospital, where the other children had been allowed to associate with the patient; but we had some good cases of sufficient isolation in very poor homes and in insanitary houses where the mother nursed the patient in a separate room and carried out all our instructions. Now that I have my scarlet fever block ready for cases I find that mild cases of this disease are difficult of diagnosis, and that it is better to leave the patient under the medical attendant till all doubt disappears rather than expose the child to infection in the hospital, and put the landlord and sanitary authorities to needless expense in stoving and cleansing the house if the previous diagnosis is not confirmed. If all private practitioners were like Dr. Benham and would take the trouble to insist on the "necessary precautions" being taken, they would lighten the hearts and lessen the responsibilities of medical officers of health in preventing the spread of these infectious diseases and would retain their own private cases as well as teach parents and guardians that they have a duty towards those entrusted to their charge. The importance of the subject is my apology for the length of this communication.

I am, Sirs, yours, faithfully,

WM. BERRY, F.R.C.S.Irel., D.P.H.,
Medical Officer of Health of Wigan.

Wigan, June 15th, 1896.

POINTS IN THE NEW LONDON UNIVERSITY QUESTION.

To the Editors of THE LANCET.

SIRS,—I crave space to consider the proposed enlargement of the present London University for the reasons that it will affect and revolutionise the position of a large portion of medical practitioners who are merely London diplomates as compared to those holding London degrees. It is an epoch-moving reform, which will or ought to give us all our proper degreed status as Doctor, as in most other countries, to be definitely grasped and respected by the public, and giving all members of the profession an equal chance of soaring in the estimation of their own ranks or attaining the highest positions of merit and importance, which under the present invidious restrictions is a galling impossibility. The common name "diploma" is now the equivalent of many a low distinction obtained by, say, plumbers from the Institute of Hygiene, or given to trade fitters at exhibitions, or even received by the *officiers de santé* in comparison to the higher grade French degrees. This is all apt to rankle, though borne with benign toleration. The adoption of the Lord Cowper Commission's proposals would tend to alter, ameliorate, and heighten our general professional status, and it would at last make the capital of England a university centre, which I venture to say is none too soon, though it is quite English to be behind the times. It would also combine the enormous and especially medical-teaching capacities of this metropolis into a real and complete London University, which would likely achieve for itself a world-wide and hereditary reputation, especially if from the start it should be under munificent and Governmental endowment.

The high principle and faithful devotion of some of our leaders in the just cause of reform of the London University shows, from their very status, that the isolated monopoly of the present class of degree holders will not be encroached upon by the movement, and the quality and facility for passing future brimful examinations without specially practical study is speciously safeguarded and assured to those to whom it appeals. It is to be hoped that now the scheme has actually been brought forward in the House of Commons the noble efforts of our able leaders will not tire or despair of moving all their ingenuities to convince those in Council and of our able Parliament of the necessity of this advance; and if they need any voice or action from members of our London medical colleges it would be not only our interest and advantage, but a high-toned duty on

Digitized by Google

our part to help with our support. In the comparative study of the European universities I find that they have been chiefly founded in one faculty—e.g., Paris, divinity; Bologna, law, &c.—so on this score it will not be out of the way for medicine to play an absorbing and an important *rôle* in the present proposed reformation.

It is also important to realise that women will be largely admitted if the present scheme be carried through. I have generally heard expressed that woman's late and prominent efforts in the universities were quite a new phase of pretty and probably fleeting activity; but my information now goes to prove that this is not so, and I hope that in this connexion it may be worth recording that in the very first universities ever formed in Europe they were allowed equal entrance with men, and for the immediate period success attended their impulsive energy. In the case of Salerno "Trotula" is a distinguished example, for she wrote (circa A.D. 1059[1]) a treatise on "Medicine and Diseases of Women," introducing as a new feature the work of Latin and Greek writers, for the nonce discarded in the great Salerno medical school in favour of their own particular hygienic methods. In Paris Héloïse was an early and a brilliant student of the university which was founded by Abélard to whom she wrote her well-known letters. I also venture to cite below extempore lines written by her (A.D. 1122) on a unique vellum funereal roll about the Abbot of Savigny, Vital, with grief and its futility as the difficult theme. Other great women writers since those lapsed days were debarred from university distinctions, but in all probability in the new university their work, beside that of the men, may be fraught with the most momentous importance and renown to themselves, and prove an honourable distinction to have freely permitted their admission. In conclusion, I would press upon our great leaders the important claims of the diplomates of the London Colleges of Surgeons and Physicians, and trust that the ultimate university authorities will have pointed out to them the justice of the claims of the Members and Licentiates to participate in a retrospective clause, which will entitle them to proceed to the Doctorate degree, either by an original thesis or by a final examination, for clearly the movement for a medical faculty at any rate arose in great part out of their disabilities. In fact, it will hardly be fair if this point be not acceded to, for it will allow similarly trained men to obtain degrees in medicine over and above the former titles.

I am, Sirs, yours faithfully,

Upper Woburn-place, W.C. H. ELLIOT-BLAKE.

(Copied from the original in Paris.)

"Flet pastore pio grex desolatus adempto,
Soletur miseras turba fidelis oves.
Proh dolor! hunc morsu sublatum mortis edaci.
Non dolor aut gemitus vivicare queunt,
Ergo quid lacrime, quid tot tantique dolores
Prosunt? Nil prodest hic dolor imo nocet.
Sed licet utilitas ex fletu nulla sequatur,
Est tamen humanum morte doloris patris.
Est etiam gaudere pium; si vis rationis
Tristicie vires ad nichilare queat.
Mors etenim talis, non mors sed vita putatur;
Non moritur mundo, vivitet ipse Deo.
Oret pro nobis; omnes oremus et ipse Christum
Et nos ad vitam perveniamus. Amen."

A blank translation running:—

"The vanished shepherd of his flock is mourned,
Let faithful throng console your deepened sorrow.
Oh, cruel fate! him, seized by the grasping jaws of death,
But neither grief nor groaning can avail that life
Nor tears; why, therefore, great and many wails?
'Tis useless, rather sore distress.
But though no usefulness is gained from sobs,
'Tis but a human phase to grieve a father's loss.
In pious duty may we yet rejoice; for if the mind
Can bridge the tide of sadness
We view a death like this as yet a life esteemed;
And, dying in this world, his resurrection is in God.
Pray he for us and pray we all that he as
Well as we may come to life. Amen."

THE DEGREES OF THE UNIVERSITY OF LONDON.

To the Editors of THE LANCET.

SIRS,—From papers sent to me by the clerk I observe that at Convocation, to be held on June 23rd, the resolution as under is to be moved by Mr. Spratling:—

"That the excessively high standard maintained by this University in conferring its highest degrees has worked an injustice to many of its graduates and is the main cause of the agitation from which the University is at present suffering. That steps be therefore taken to co-ordinate these degrees with those conferred by the other British universities: 1. That for this purpose powers be obtained to confer the title of 'Fellow of the University' upon all graduates who up to the present have attained, or shall in the future attain, to the highest degree in their several faculties, according to the present high standard. 2. That the degree of Master or Doctor be conferred upon all Bachelors in the several faculties who have reached, or shall hereafter reach, such a standard in Honours in their final examination as the Senate may deem adequate."

Some years ago Convocation discussed the same subject very fully at a large meeting and rejected a similar resolution, and I myself travelled a long way and at considerable inconvenience to vote against it. I object to the resolution above on the following grounds. First, I do not wish to be credited with or have attached to my name any title I have not earned by hard study and a legitimate and searching examination; and it is just "the excessively high standard maintained by this University in conferring its highest degrees" which renders them, in my estimation, of supreme value, and places them above all others in this or any other country. Secondly, I object to gentlemen, Bachelors of the University, obtaining the higher degree without having undergone the like study and the like examination, for I look upon such a proceeding as unjust to myself and my *confrères* in the medical faculty. I trust, therefore, that the proposition No. 5, to be moved at Convocation next Tuesday, will meet general and successful opposition.

I am, Sirs, yours faithfully,

Truro, Cornwall, June 16th, 1896. WM. DALE, M.D. Lond.

CHOLERA IN EGYPT.

To the Editors of THE LANCET.

SIRS,—From the spring of 1884 to the autumn of 1895 Egypt remained perfectly free from malignant or Asiatic cholera. During this period of eleven and a half years not one single death was attributable to the disease throughout the length and breadth of the land. In September, 1895, suspicious cases occurred at Menzaleh, but it was not until Oct. 12th that cholera was unmistakably recognised. Writing on Jan. 28th, 1896, Dr. Rogers Pasha says: "I have no doubt that when the full report of the present epidemic comes to be written the probability, if not the certainty, of the introduction by pilgrims will be fully established." The disease rapidly spread over the Delta and even reached Cairo, but by the end of January, 1896, one place alone remained infected. For a period of ten or eleven weeks there was absolutely no cholera in Egypt except at Alexandria, where fresh cases continued to occur at short intervals. It was not until the latter part of April that the provinces became re-infected, the contagium this time appearing to be more virulent than at first, probably on account of the increasing stagnation of the water-supply. For the sake of brevity I have stated my argument in dogmatic fashion, but writing at a distance and with necessarily imperfect knowledge I am quite prepared to accept correction. My suggestion is that cholera, having been imported in the first instance from the Hedjas, was successfully dealt with except in Alexandria, where it continued to smoulder for close on three months after it had been extinguished elsewhere, and that re-infection of the rest of Egypt subsequently took place from this secondary focus.

Alexandria has the misfortune to be very badly sewered, and it is in this wealthy town also that the rights conferred by the capitulations especially hamper all efforts at sanitary reform. To the best of my recollection the cholera epidemic of 1883-84 lingered in Alexandria long after it had worn itself out in the country generally, but unfortunately I have no means of verifying my impression. The money loss to Egypt from an epidemic of cholera is very great, but if the sanitary department were adequately financed (to use the expression of a recent writer in the *Pall Mall Gazette*) it should be possible in this respect to safeguard the national treasury. Perhaps in this connexion you will allow me to quote from a paper of mine which saw the light in 1892:—

"From a cosmopolitan point of view it is evidently high time that one of two things should be done in the interests of the health of the world. The pilgrimage should either be abolished or else subjected to efficient sanitary control. Till one or other of these measures is adopted Europe can never be safe from the attacks of the most deadly of pestilences. The present epidemic at Hamburg and elsewhere most unquestionably owes its origin to the Meccan pilgrimage. The Hadjis on their return along the various caravan routes have spread the germs of the disease broadcast, and though for this year the virulence of the outbreak

[1] Darenberg: Ackermann.

Digitized by Google

eems now to have abated, yet who will answer for what may appen in the immediate future. One thing is certain: if cholera hould again reach Egypt let the bondholders beware. Dervishes and nundations are not the only enemies to be repelled at the cost of a nillion per annum. Let them spend something also on sanitary ssurance. The sanitary administration possesses a most efficient irector, but he lacks the means to execute his designs. He is comelled to make bricks without straw, and often the very clay is refused o him. Allow him the necessary funds and before long the country, urged of its sins against hygiene, will, with its glorious and life-giving limate, be second to none in the world for salubrity."

I am, Sirs, yours faithfully,

St. John's, Woking, June 15th, 1896. H. R. GREENE.

THE CAUTERY IN OVARIOTOMY.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 16th Mr. Tait claims that ıe has discovered the true principle of the cautery as used ıy Mr. Baker Brown and Dr. Keith. This shows such a ant of memory of his own writings, and want of knowledge f the writings of others, that it seems almost beyond belief. n 1883 Mr. Tait wrote: "When he (Dr. Keith) removes he clamp, that part of the pedicle which has been embraced ıy it is shrivelled and translucent like parchment." Mr. Tait ıad therefore either seen the cautery applied or had had its node of application explained to him. He has evidently orgotten this and also the method of application, for he peaks of great physical exertion and of the time required ıeing twenty or thirty minutes. There is no special exerion, and when we used the cautery irons at a dull red, never black, heat seven or eight minutes was the average time; ıow, by using them at a white heat three minutes are suffiient. In Dr. Skene's work on "Diseases of Women," pubished in 1888, the principle of action is described in the ollowing words: "The object is to desiccate at least half an nch of the stump and to avoid charring it." In a paper ın the Cautery in THE LANCET of April 30th, 1892, I said 'the compressed part of the pedicle will, if all be satisfacory, have the appearance of a piece of horn. ..... Bleeding ıever occurs after the abdomen has been closed, and to preent it at the time of operation the two essential points are he screwing up tight and the heating of the blades of the lamp." The amusing part is that Dr. Keith found out the xplanation only after performing several operations on ınimals, and now Mr. Tait, having partially forgotten or erhaps not thoroughly understood what he described hirteen years ago, tells us that operations on animals are nnecessary. I am, Sirs, yours faithfully,

Charles-street, W., June 10th, 1896. SKENE KEITH.

"ANTERIOR COLPOTOMY."

To the Editors of THE LANCET.

SIRS,—I should be glad if you would allow me to record in THE LANCET my remarks on Dr. John Phillips' paper on 'Anterior Colpotomy" read at the last meeting of the Obstetrical Society. They were not forwarded owing to a ailure of the post-office arrangements.

I said that the difficulty of making and keeping the vagina ıseptic as set forth by Dr. Phillips seemed to me a very erious objection to the removal of intra-peritoneal disease ıy anterior colpotomy; and that another important objection vas the fact that, when small tumours or inflamed ovaries equired operation, their removal was frequently so difficult hat it was not possible to operate with any safety by nterior colpotomy, whilst the easier cases should have no nortality, except from purely accidental causes, if done by bdominal section. Under these circumstances it seemed to me hat to operate on intra-peritoneal pelvic conditions through he vagina must add to the risks in all cases in which this plan night be contemplated. I should like to add that the cases n which the ablation of inflamed ovaries and tubes is required, ut in which it is almost or quite impossible to completely emove these organs even when the parts have been fully xposed, are sufficiently numerous already without the perator handicapping himself by the difficulties and dangers f working through a strictly limited space of doubtful sepcticity. It seems to me certain that the plan of operating ıy anterior colpotomy must not only cause greater danger to he patient but that it must also lead to an increase in the umber of imperfect operations. The evils of these imperect operations do not appear in statistical tables. They can e discovered only by the study of the after-histories of cases. Personally I have performed few operations which could have been done by anterior colpotomy. I have not performed any operation in which I can believe that the slightest advantage could have been gained by adopting this method, and I have done many successfully in which an attempt to operate through the pelvic outlet would have ended inevitably in failure.

I am, Sirs, yours faithfully,

Portman-street, June 15th, 1896. JOHN D. MALCOLM.

THE ST. JOHN AMBULANCE ASSOCIATION AND ITS LECTURERS.

To the Editors of THE LANCET.

SIRS,—The St. John Ambulance Association has, with the coöperation of the medical profession, accomplished much that is excellent, and I, like other medical men, have taken great pleasure in the work done for it. Consequently, I was not merely surprised but sorry to find this Association taking up a position in regard to the profession which has compelled me to resign my honorary membership. The matter will probably be a surprise to most if not all of the ambulance lecturers, and it seems to me of such importance that I venture to give it publicity in your columns. The facts need occupy but little space. The authorities of the local Young Women's Christian Association requested me to give them lectures on nursing. They gave me various reasons why they did not propose to form a class in connexion with the St. John Ambulance Association, among others that the pupils did not wish to enter for any examination. The request was only for two lectures, and it was at my own suggestion that the number was increased to six. A lady who is one of the Ambulance Brigade nurses promised both the superintendent of the Young Women's Christian Association and myself independently that she would give assistance in her private capacity. The hour of the lectures was such as not to interfere with any brigade work. To my astonishment this lady informed me later that she must withdraw from her promise because the ambulance authorities "could not give their sanction." Wishing to avoid any unpleasantness, I accepted the position and gave additional time and work to make up for the loss of her friendly assistance. Much to my annoyance, a few days later I was informed by a medical neighbour that the ambulance authorities were criticising my conduct in giving such lectures as unfriendly and even shabby. A letter to, and interview with, the local honorary secretary, Mrs. Colegrave, showed me that her part in the matter had merely been to carry out instructions from headquarters, so I wrote asking that I should be informed from headquarters: "1. Whether they consider the fact of a doctor having delivered lectures under their auspices should preclude him from doing any similar work at the request of others? 2. On what grounds they used their influence to prevent a lady who was willing in her private capacity to give me some assistance with a nursing class from carrying out her intention?" The following reply was communicated to me. (The italics, &c., are Sir Herbert Perrott's.)

"St. John Ambulance Association, May 23rd, 1896.

"DEAR MRS. COLEGRAVE,—With reference to Dr. Carruthers' letter which you have submitted to me, my opinion is, while in the abstract there is nothing to prevent a medical man from lecturing in accordance with the syllabus of the association whenever and wherever he pleases, the fact that he has accepted the position of honorary life member offered him in recognition of his services on behalf of the Association *should tend to induce him not to give lectures on the lines of the Association except under its auspices.* As superintendent of the Norwood Nursing Division you are fully within your right in forbidding one of your enrolled nursing sisters to assist in any way at lectures on the subject of first aid or nursing, whether in connexion with the Association or not. In so doing she cannot be said to be acting in her private capacity.

"Yours faithfully,

"HERBERT C. PERROTT.

"If Dr. Carruthers and the nursing sister wish to instruct classes on their own account it would be more honourable in them to resign honourable life membership and membership of the nursing division respectively. By not doing so they are leading people to infer that they are acting under the auspices of the Association, and as their pupils will not be examined by our examiners, or get our certificates, it is very hard on them—that is, the pupils. H. C. P."

While this letter skilfully evades a categorical reply to either of my questions, it left only one course open to me, for the postscript to all intents and purposes called upon me to resign because I had lectured to the Young Women's Christian Association class. My reply is subjoined.

"44, Central-hill, Norwood, S.E., June 11th, 1896.

"DEAR SIR,—I am much obliged for the information contained in your letter of May 23rd to Mrs. Colegrave (of which I have this day

Digitized by Google

received a copy). As I cannot allow myself to be prevented from giving help to other people when asked, I beg herewith to return my diploma of honorary life membership and to resign that position. It might have been better if you had taken some steps to ascertain the facts before writing your postscript, as the statement (implying a somewhat serious charge) that in taking this class I was 'leading people to infer that I was acting under the auspices of the Association' is entirely erroneous and unfounded. I was specially requested to take it as a class independent of the St. John Ambulance Association, sufficient reasons being given me to justify my acceding to such a request, and its independence was perfectly well known to all concerned. You also seem to assume that the lectures in question were 'in accordance with the syllabus of the Association.' This was not the case, as there were considerable additions and not a few omissions as compared with the contents of that syllabus. I informed Mrs. Colegrave when I asked for a copy of your letter that I intended to send the correspondence to the medical press. "I am, faithfully yours,

"S. WM. CARRUTHERS.

"Lt.-Col. Sir Herbert Perrott, Bart."

I am, Sirs, faithfully yours,

Norwood, June 12th, 1896. S. WM. CARRUTHERS.

THE REMUNERATION OF MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—It is very noticeable that there are marked signs in the profession of discontent and dissatisfaction at the rate of remuneration and treatment received by the general practitioner. There is also ample proof that this feeling is gaining force like a rolling snowball, and that members of the profession are beginning to recognise—tardily enough, but surely—that combination for their general interests is the only way in which they can hope for relief. It is much to be regretted that the forces cannot be arranged under one banner. We have more than one medical defence society, many "associations," and a body of medical men working somewhat after the fashion of the Incorporated Law Society. All of them do useful and honourable work. It is perfectly obvious, however, to any thinking mind that the very number of these institutions means disunion in its worst form. Scattered forces, apathetic leaders, petty jealousies and bickerings, the result of attempts at personal advancement under the guise of disinterested work for the profession,—all these and similar causes hinder, and very seriously hinder, that universal cohesion so essential to the success of any great movement. One important matter concerning which members of the profession as a whole are singularly indifferent is the benefit which would almost certainly result from our parliamentary representatives taking an interest in the question. There can be no question that an amendment of the Medical Acts dealing with unqualified practice is urgently needed and is only to be obtained by political pressure. The influence brought to bear by the united action of our profession, exercised directly or indirectly, would be enormous if properly used at election times, and our cry should be a reform of the Medical Acts. Surely it is a monstrous injustice to medical men that when they have conformed with the law of the land by obtaining degrees or other qualifications at the expense of much labour and pecuniary sacrifice they should have to compete against charlatans of all kinds. Is it not an anomaly strange and ridiculous that the General Medical Council can remove a man's name from the Register for nefarious or criminal conduct, and yet that he continues to thrive and practise, though he cannot recover fees at law or sign a death certificate? There are instances of this strange state of affairs now in London well known to many members of the profession.

Overcrowding in the ranks of the medical profession is so notorious that allusion to it is superfluous. The number of ways in which a young man may obtain a diploma, the comparative cheapness of the minimum education for the minimum legal qualification, and the exaggerated ideas possessed by the public of the emoluments of successful medical men—all induce the middle-class parent to regard the profession of medicine as the key to solve that most thorny problem, "What are we to do with our sons?" It is certainly true that in any walk of life attended with competition everyone cannot succeed. The qualities of integrity, steadiness, thrift, tact, common sense, and indomitable perseverance are as essential to success in medicine as in law or in mercantile pursuits. Excellent and complete professional knowledge is of the first importance, although this is probably less essential in medicine than in many other occupations or professions. It is a common and every-day fact that it is not men of the highest professional attainments in medicine who of necessity obtain the highest professional success from a pecuniary point of view. A remarkable fact regarding medical education may well be pondered. We instruct our young men in what can be acquired during five or six years of a knowledge of the most recondite problems ever presented to man in the study of the phenomena of disease. At the end of this time a clever and industrious student may, especially if he has held hospital appointments, be well practised in the principles of his profession and trained in accuracy of thought and powers of close observation and reasoning. But he will be ignorant regarding what may be termed, without offence, the business side of his profession. Among the many curious doctrines which have survived regarding the practice of medicine there is one which is not to be spoken of with contempt, since it has been held and promulgated by some of the leading men of the profession. To put it plainly, parents who have expended large sums of money to give their son a medical and university education will be surprised to hear that he has been told by some of his teachers that medicine is a noble profession, that it has rewards not to be measured by money, and that no one who practises it in a proper spirit should regard the question of fees. These phrases, or similar ones, commonly form the stock-in-trade of some of the introductory addresses at our medical schools, and as they are often delivered by men of light and learning they merit some attention and examination. No one can deny the first two propositions, but the last requires very serious consideration at the hands of the profession and the public. This platitude, which has probably descended directly from remote periods, when medicine was in the hands of the priesthood, has long held ground. It is remarkable, however, that any critical observer who closely watches the practice of some of those who most strongly denounce the question of fees will soon be able to formulate doubts as to the sincerity of their actions. Either it is right for a physician, surgeon, or practitioner to be paid for his services, or it is not, and, if a man holds that it is not, then he should refuse to receive pecuniary emoluments at all and practise as a pure philanthropist. Through a mistaken kindness many of the most excellent and large-hearted men of our profession, possessed of good private means, give away their services freely, and the damage they do to the pecuniary position of their less fortunate and poorer brethren is incalculable. There can be no doubt that it should be a thought on the part of our teachers in the larger schools, not only what is to become of their students while they are under their immediate care, but what is to become of them afterwards. Every man will find his level in the struggle of life, but there can be no question that the sympathy and aid of the leading men of the profession should be extended to the rank and file far more than is at present the case. The younger race of consultants, and especially the students, must never overlook the natural law that increase in the supply of any commodity leads to diminution of its price. It is a well-established fact that a superabundance of any kind of skilled workmen will lead to a cheaper rate of wages for that particular class of individual. Every man, professional or otherwise, has a right to work for what reward he chooses, and the forcible methods of dealing with "blacklegs" advocated and employed by some of the more ardent disciples of our labour leaders can hardly be extended to professions the members of which are agitating for reform.

Dr. Kehlman, speaking at the meeting of the San Francisco Medical Society on Oct. 8th, 1895, said "be was ready to defend the cause of the practitioners with sword, bullet, or pen." We are less truculent in this country, and the latter weapon is, perhaps, less potent for sudden reforms than the two former. Great changes and great improvements are seldom to be wrought in a day, and more can be effected by slow and sure progress than by sudden revolution. Behind the story of six-penny clubs and cheap medical associations comes the tale of overcrowding in the profession, and this is directly fostered by the competition of medical schools and by qualifying examinations which demand a minimum of practical knowledge. These and similar reflections show how vast is the subject of medical reform, and what an urgent need there exists for a universal association of medical men for the protection of their own interests. The lines upon which the coming generation should work are clear enough. We should

Digitized by Google

endeavour to raise the professional knowledge and status of medical men and make them worthy of proper professional emoluments; and we should, by all means in our power, induce our students to combine, wherever they are, against cheap clubs and similar abuses. All hospital staffs, especially in country towns, may well take to heart the excellent example which was set them at Swansea. They should definitely take up the line that a hospital exists for charity in the first place and for medical education and progress in the second. The "sixpenny doctors" will still exist; they will, however, become fewer, and be recruited from the inferior grades in the profession. The public will in time become educated to the danger and uselessness of such modes of obtaining professional advice. There are many meetings for purely professional purposes held in our larger cities and towns. The thought of an annual congress for the discussion of matters of professional reform and political combination may well engage the attention of all our associations of medical men during the present year.

I am, Sirs, yours faithfully,

June 15th, 1896. M.D.

MEDICAL BULLETINS, PROFESSIONAL ETHICS, AND COMMERCIAL SPECULATION.

To the Editors of THE LANCET.

SIRS,—During the past few weeks there must have been many like myself who have been vainly waiting and expecting some one in the higher ranks of the profession to utter a protest or ask for an explanation of the unedifying spectacle which the illness of the distinguished President of our Royal Academy has been the means of placing before us. One cannot recollect a case where the constant reiteration of the medical attendant's name has been carried to a greater length than in the sad illness of this illustrious man. For some weeks now the public has been daily (often twice) treated, not merely to information about the progress of the sufferer himself, in which, of course, we all have a sympathetic interest, but also to the important fact that his medical adviser, whose name is each time given, visited him at such and such an hour. What, Sirs, is the purpose of these details? The public may want to be constantly informed of the distinguished patient's condition, it may also interest them to know who is in charge of the case, but after having given the latter information on two or three occasions, what can be the purpose of its constant appearance unless it is to keep the attendant's name before the public? It may be said that the practitioner is not responsible for the mistaken pressman who is desirous of every detail of information for "copy," but such an excuse is too feeble to bear investigation. Undoubtedly it is almost impossible for a practitioner to avoid the publication of his name in the early days of the illness of any distinguished person, but every medical man must and does know that the profession to which he belongs, and of whose honour he should be jealous, strongly disapproves of anything that could be interpreted as an advertisement, in which the attendant acquiesces. A few polite lines to the editors of the papers in which such objectionable statements had repeatedly appeared, requesting them only to give the substance of the bulletins without time after time mentioning the attendant's name, would be certain to have the desired effect.

In spite of our so-called professional ethics (surely rapidly becoming a name only) this form of abuse has become so frequent of late that I would not have considered the present instance anything more than a particularly fine specimen of its kind were it not that a more serious offence has within the last three weeks been added to it. We have been informed and startled by announcements made at various times in at least two of the morning papers that the improvement which fortunately had taken place in the President's condition had been fairly maintained and that this was attributed to inhalation of ozone introduced into the treatment by the practitioner in charge of the case whose name is each time given. Then, Sirs, one felt surprised that no voice was raised to ask if such announcements were in keeping with the traditions of our profession, and, if not, were we to congratulate ourselves on the innovation? But the climax was yet to come. Last week I, in common, no doubt, with many others and thousands of the lay public, received the enclosed prospectus from a commercial ozone company in which you will find the following passages: "In addition to the uses for industrial purposes to which ozone may be put it is probable that in future it will play a very prominent part in medical practice, and the following extracts from London newspapers are cited in support of its value. From the *Times*, May 26th, 1896: "Sir John Millais' condition was reported last night to be satisfactory. It is stated that to meet certain complications which arose in the condition of Sir John Millais Dr. Hames, who has been in constant attendance since the operation, decided on the application of constant inhalations of ozone. This was immediately followed by beneficial results which have since continued." From the *Standard*, June 1st, 1896: "The marked improvement in the condition of the President of the Royal Academy noted on Saturday morning has been fairly maintained, and this is attributed to the ozone inhalations introduced into the treatment by Dr. Hames." This prospectus was followed by the *Standard* bulletin: "The ozone treatment introduced into the case of the President of the Royal Academy continues to give most beneficial results, enabling the patient to obtain a considerable amount of good rest. On Saturday morning Dr. Hames was able to issue an exceedingly favourable statement as follows," &c. Alas! Sirs, to what have we come! Well may men often smile when professional ethics are mentioned, and rapidly turn conversation to a subject where their words have some pretence of meaning in them. One is pained to think that the illness of a distinguished man should be made capital of for a commercial puff, and humiliated when one sees the name of a member of our profession appear in the latter. I presume, of course, queer though the matter looks, that this prospectus has been issued without the knowledge and consent of Sir John Millais' medical attendant. Anyhow, I think he owes it to his profession to clear the question up without delay. Should he be unwilling to do so it seems high time that the authorities of the Colleges to which he and I belong should take the matter in hand. I enclose my card, and remain, Sirs,

Yours faithfully,

June 16th. M.D., M.R.C.S. & L.R.C.P., &c.

THE BATTLE OF THE CLUBS.—XXXIII.

(Continued from p. 1675.)

THE GENERAL MEDICAL COUNCIL AND THE MEDICAL AID ASSOCIATIONS.

AT the meeting of the Executive Committee of the General Medical Council of June 1st the following letter was read:—

Friendly Societies' Medical Alliance Council,
April 21st, 1896.

DEAR SIR,—At the annual conference of the above, held at Wednesbury on Easter Monday, Mr. S. Pride of Luton, Mr. Dickinson of Lincoln, and Mr. M. J. Williment of Norwich, were appointed a deputation to wait on the General Medical Council at their next meeting for the purpose of laying before them the present attitude of some members of the medical profession towards friendly societies' medical associations. If you will arrange the day and hour most convenient to the Council to receive the deputation and acquaint me, I will then arrange for the deputation to be there at the appointed time and place.

Yours most respectfully,

W. J. C. Miller, Esq. JOHN BROWN, 26, Markham-street, York.

It was resolved "that Mr. Brown be informed that the executive committee cannot recommend the General Medical Council to receive the deputation referred to."

It may be that the executive committee was within its powers when it intercepted a communication of this character and deprived the representatives of the Friendly Societies' Medical Alliance of an opportunity of stating their grievances as to the attitude of "some members of the medical profession" towards their associations. No doubt they base themselves on the conclusion of the Council that such matters are not within their jurisdiction. All the same we somewhat regret that the deputation was not received. These associations are sadly ignorant of the feeling of the medical profession—not "some of its members," as the letter would have us believe—on the subject of such associations and of the part they have tried to play in trying to degrade medical practice and medical practitioners. They are even more misinformed if they think that the Council would be willing to force medical men to alter their attitude of hostility to such a system. A few minutes' interview with the General Medical Council might have undeceived them on both points. They will at any rate realise that they have nothing to

Digitized by Google

expect from the General Medical Council. The associations will receive more and more proof that the profession as a whole is against them, and will do well to come to terms with it confining the privileges of their associations to working men and their families and paying them properly as they are well able to do.

If the General Medical Council is so restricted in its disciplinary functions the medical corporations and the voluntary associations of the profession are not so restricted and may make their power felt. If the voluntary associations of the profession can be moved to a full discharge of their duties in this matter there will be little need for the use of the disciplinary power of the bodies.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Jubilee of the Swinton Schools.

THE report of the Poor-law Schools Committee on the barrack schools of London has drawn attention to some of the workhouse schools in the provinces. Now those at Swinton, about four miles from the city, under the management of the Manchester guardians, are among the largest in the country, and their jubilee has just been celebrated. They were opened in February, 1846, and provide accommodation for about 760 in the main building and 110 in the hospital and receiving wards. When they were built there was no controversy about the "barrack" system, the "cottage home," and "boarding-out." The chief aim was to get the children away from the workhouse with its degrading and vicious influence, and as there were many of them it seemed obvious that a large house was required to hold them. There are now about 750 boys and girls there, chiefly Manchester children, but a few are boarders from the Barton and Wigan unions. Though schools would not now be built as in 1846, it must be allowed that these have been well and humanely managed. The children may be divided into two classes—those who spend all or the greater part of their school life in the school, and those who come and go, entering and perhaps leaving in the same quarter and almost certainly in the year, for the guardians, of course, have no power to detain a child against the will of the parents or legal protectors. Of 700 in the school a year or two ago about 600 were liable to sudden removal, so that it is easy to understand that with this shifting population the maintenance of discipline and "character" is no easy task, and yet we read "that there is no record at the Manchester workhouse—at least, for the last sixteen years—of any boy who had gone through the school entering the workhouse to live there. Many have worked themselves into good positions and they and others speak kindly of their early life." Besides the scholastic work the boys learn various trades—as tailoring, shoemaking, gardening, &c. There is a good swimming-bath, which is very popular, and many of the lads would do credit to any swimming club. A short time since an article appeared in the *Manchester Guardian* containing some severe criticisms of the London schools, in which the Swinton schools were incidentally mentioned as being the largest in the country, and this article was thought likely by the guardians to make the public believe the Swinton schools were deserving of the same condemnation. Mr. McDougall, chairman of the schools committee, thought it necessary, therefore, to refer to the matter at the meeting of the guardians. The *Guardian* said that the "barrack" schools were: "(1) directly injurious to the health of the children; (2) detrimental to their mental development; (3) harmful to their morals; and (4) more costly and more difficult to maintain in proper working order than smaller institutions would be." Mr. McDougall said they were almost free from ophthalmia, though many years ago it was prevalent, but was got rid of by simple means. The children no longer used common wash-bowls; each one had a jet of clean water to wash with and had three clean towels a day. It was said that "eczema and other skin diseases are always prevalent" in "barrack" schools, but it was not so at Swinton. And as to their physical development, he said that the remark that the boys were "stunted and narrow-chested" and most of the girls "below the normal height, and the appalling monotony of their lives makes them tend to become dull, sullen, and mechanical, and to lose interest alike in work and play," was certainly not the case at Swinton; "if there was one thing on which they prided themselves it was that when the children played they were merry, and when they were working they felt their work had some purpose. ..... The guardians sought to make their lives bright and to fit both boys and girls to earn their living." The cost per week is a little over 5*s*., and the guardians are not anxious to make it less, for they wish the children to have good food and clothing. Of course, when one knows the places from which most of the children come, the character and physical condition of the parents and the lives led by a large proportion of them, it would be marvellous if the signs of degeneration marking the parents did not descend to their offspring. The short period during which the majority are in the school is not sufficient to overcome the disadvantages of their start in life, but where more time is given both boys and girls improve physically in a remarkable manner. It is said that the headmaster has many applications for any of the girls who will go into domestic service, which, however, is not always popular with them. Many go to factory work or are apprenticed. On the whole I may say that if the metropolitan "barrack" schools had been as intelligently managed as the schools at Swinton the report concerning them would have read somewhat differently.

The Coronership.

At the last meeting of the City Council Mr. Smelt, barrister, who had been for many years deputy coroner, was appointed coroner in the place of the late Mr. Herford at a salary of £800 a year. The late coroner had been non-existent — so far as the performance of the duties of the office was concerned — for at least fourteen or fifteen years, with the exception of what he no doubt considered the important duty of receiving the fees. By the conditions of his appointment he was paid by fees and was irremovable, and he retained his office to the end. He was a man of strong will and some pugnacity and in his active days was usually in antagonism with the medical profession of Manchester. However, nothing but good should be said of the departed, and as the retention of his office long after he was incapacitated was no doubt legal he perhaps considered—for his opinions on many matters would by most people be thought eccentric—that it would be illegal to resign. At the council meeting Professor Sinclair made some observations criticising Mr. Smelt's proceedings so far as they related to medical evidence and post-mortem examinations, and said that one of the objects of a coroner's inquest was to ascertain the cause of death. On taking his seat for the first time as coroner for the city, Mr. Smelt "made some remarks on the position and duties of coroners" and wished "to brush away" a good deal of misunderstanding. He said inquests were held for the benefit and protection of the public. "It was the duty of the coroner's court to ascertain the cause of death, not for statistical, medical, or scientific purposes, but to find out whether any person was responsible. ..... So long as he presided in that court he should never order a post-mortem examination unless he believed it to be absolutely necessary." His reasoning seems peculiar, for after stating it to be a duty to ascertain the cause of death he goes on as follows: "If the jury were satisfied that a case was a perfectly straightforward one and that nobody was to blame, why go to the trouble of ascertaining the *exact* cause of death?" It is a duty, therefore, to ascertain the cause of death, but not the exact cause; it need only be known inexactly as it is merely for the benefit of the public, though it is not clear how inaccuracy is for the public benefit. Is this view in exact accord with common sense? In a subsequent part of his address Mr. Smelt said that where it was possible he obtained the evidence of gentlemen who were in the habit of making post-mortem examinations and of giving evidence in courts, because he thought it better that they should have the evidence of experts. This is a wise proceeding and will be generally approved, especially when it is wished to ascertain the exact, and not the inexact, cause of death. No doubt the original intention of the court was to learn if death had been the result of foul play, but it is notorious that even "intelligent" juries often fail to return correct verdicts, especially where the coroner is a lawyer and not a medical man; but even if this were not so there is no reason why the coroner's court should not aid in rendering the Registrar-General's returns

Digitized by Google

ccurate instead of misleading by giving the exact, and not he inexact, cause of death. In concluding his address ie said that "he had had practically very little difficulty vith jurors and medical men, and no trouble at all with he legal profession, during the eighteen years he had acted s deputy-coroner, and he had not a regret to express for his ction in relation to them, or as another report gives it, "in onnexion with those people." However, he bears no malice owards the "medical people," for he hoped their good elations would continue. He concludes by wishing "to mpress upon the public" (including, of course, the "medical eople") that the institution of the court was for the pro-ection of the public alone, and not for medical or scientific urposes. It would always be his duty to protect the public, nd save the time and money of the jury and ratepayers.

June 16th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Harveian Oration of the Harveian Society of Edinburgh.

DR. PEEL RITCHIE (Fellow and Past President of the Royal College of Physicians of Edinburgh, Fellow of he Royal Society of Edinburgh, &c.), the President f the year, chose for the subject of his Harveian ration the Early Days and First Knights of the Royal College of Physicians of Edinburgh. He endeavoured to how—first describing the state of scant medical teaching nd medical examinations in Harvey's time, the want of nfirmaries and of opportunities for meetings for conference pon medical subjects, not only in England, but in Scotland—he great good done by the establishment of the Edinburgh College of Physicians in contributing to the inauguration of hose necessary reforms, and also as regards Scotland in reparing and publishing a pharmacopœia. Four attempts ad been made to erect a College subsequently to Harvey's irst lecturing, and each of the first three he associated with Harvey. The fourth attempt was made (the causes which ad led to it being described) in July, 1681, chiefly at the nstigation of Dr. Robert Sibbald. To bring influence to ear on King Charles II. and his brother the Duke of York, hen in Edinburgh, at Holyrood, as the King's Commissioner, he influence of their physician, Sir Charles Scarborough, as sought and at once obtained. Very powerful opposi-ion was made to the scheme by the same four oppo-ents upon all the four occasions. Great efforts had to e exerted, therefore, to conciliate them by modifying he demands in the Charter. The opposition arose rom the archbishops and clergy who were associated vith the universities as Chancellors, &c.; the universities, vho feared their prerogative, would be interfered with; and he town council, who were the patrons of the University of Edinburgh, and by the chirurgeons, whose rights would be disturbed. On the fourth occasion the nobility also objected. The aid of the Earl of Perth and Lord Melfort was sought to essen their opposition, whilst Scarborough secured the good vill of the king and the duke. Of the physicians associated vith Sibbald, Dr. Andrew Balfour had been a pupil of Harvey and an intimate acquaintance of Scarborough; Archibald Pitcairn was one of the strongest supporters of Harvey's views in the country; Thomas Burnett was known by he importance of his works; and Sibbald seems to have known Scarborough when in London previously. On St. Andrew's Day, 1681, the Charter of Constitution was obtained, and mmediately the College set to work to carry out the reforms required for the improvement of the profession so far as the College had power and jurisdiction. The first reform was he compilation of the Edinburgh Pharmacopœia, and although this was done within two years the opposition of some of the Fellows prevented it being published for six-teen years. The second effort at reform was the establishment of a dispensary for the benefit of the sick poor in the city and suburbs. This was carried on very constantly, and from t ultimately was developed the Royal Infirmary, towards the origination of which the College largely contributed, and undertook to give attendance upon the patients without fee or reward, the Fellows attending in rotation two weeks at a time. The third great effort on the part of the College was instituting an examination for the Licence required by all physicians practising in Edinburgh or joining the College. One annoyance the Fellows had to tolerate was that they had no power to examine Scotch graduates, and from the nature of the degrees granted by some of the universities the examination of their graduates was very necessary, more so than in the case of those applicants who were Continental Doctors of Medicine. The latter had all previously "laureated" and studied abroad for years. The examination introduced consisted of three stages—(1) theoretical on the institutions of medicine; (2) on two "Aphorisms" of Hippocrates; and (3) on two practical cases. One use of the dispensary seems to have been to supply "practical cases" for these examinations. This form was regularly used, and the examinations conducted by two specially appointed examiners, and they were carried on in the presence of the sederunt of the College, the assembled Fellows being the judges, whether the applicant was to pass or not. These examinations, or "tryalls," were continued for many years. At the request of the University authorities, when the first applicants for the Edinburgh degree of Doctor of Medicine applied, these examinations were undertaken by the College of Physicians, and at first conducted in their place of meeting and with the dispensary patients. The only charge made by the College was a contribution to the funds of the dispensary, which were distinct from those of the College itself. When a professor of physic was appointed the examiners met with him in the library of the University and there conducted the examinations. When another of the physicians was appointed professor of the institutes a faculty was formed and they conducted their own examinations thereafter. The fourth great effort on the part of the College was the instituting of the rudimentary medical society conferences, previously commenced by Sibbald in his own "lodging." The President, Dr. Archibald Stevenson, delivered the address at the first College conference, the subject being Polypus of the Heart. These conferences were continued for twenty-five years and were stopped by the action of Dr. Archibald Pitcairn. They seemed to have paved the way for ultimate development of the societies of the present day, starting with the Royal Medical Society of Edinburgh in 1734. The orator then narrated to whom the merit of these important reforms was to be assigned, and showed that the chief acting spirits of the early days were nine. He also indicated that his reason for his title of "the early days" was that from the origination of the College on St. Andrew's Day, 1681, to December, 1684, represented a period of two years and eleven months, during which the minutes of the College were kept, and that it was within that short time that the four great reforms were introduced. To distinguish that short period, from the minutes of the College business kept, after a hiatus of ten years, from 1694 to the present time he had designated it the "early days." Of the nine acting Fellows he showed the parts each had performed, and concluded that the honour of inaugurating the reforms are chiefly due to Dr. Archibald Pitcairn and four senior Fellows, who were knighted—Sir Archibald Stevenson, the first president; Sir Robert Sibbald, the second; Sir Andrew Balfour, the third; and Sir Thomas Burnett, who was not elected president till 1696; Dr. Ritchie concluded by an account of these four knights, especially Stevenson, Balfour, and Sibbald, the day of whose death and place of burial he had ascertained.

Proposed New Pauper Lunatic Asylum for Edinburgh.

As the result of conferences which have lately been held between the city parish council and the managers of the Edinburgh Royal Asylum to consider the question of erecting a new asylum for the accommodation of pauper lunatics it has been agreed that application should be made to the General Board of Lunacy to have the city parish constituted a separate lunacy district under the provisions of the Lunacy Districts (Scotland) Act, 1887, and for authority to erect an asylum in the new district for the housing of not less than 400 pauper lunatics. Pauper lunatics belonging to Edinburgh have been accommodated in the Royal Asylum at Morningside since the years 1842 and 1844, when the managers of the asylum received the sum of £3210, in consideration of which they became obliged to maintain in the Royal Asylum at their lowest rate of board all insane pauper patients belonging to Edinburgh, whatever their number might be. It was expected at that time that such patients would never exceed 105 in number, but lately there were as many as 365 pauper lunatics accommodated in the asylum. This resulted in such an overcrowding of the asylum that the managers have had to refuse applications for admission of private patients and have been obliged to apply to the Edinburgh parish council for a modification of the agreement,

Digitized by Google

and to that the council consented. 105 pauper patients are to be accommodated at Morningside until the end of the year 1914 in order to wipe out the debt incurred by building additions to the asylum for the accommodation of these patients.

Royal Society of Edinburgh.

At a meeting of the Royal Society a paper by Mr. Frank J. Cole was read by Professor Cossar Ewart on the Cranial Nerves of Chimæra Monstrosa, with discussion of the Lateral Line System and of the Comparative Anatomy of the Chorda Tympani Nerve.

Edinburgh Royal Infirmary.

At the meeting of managers held this week the plans for the new gynæcological department were laid before the board, as well as a report on the subject by the architects. The new pavilion is to be built on the site of the old Sick Children's Hospital. It is proposed that the basement be used as a bathing department, the first floor as an ordinary ward, and the second and third floors for gynæcological patients, while additional accommodation for the nurses would be provided on an upper floor, to which the main staircase would be carried. The plans were approved and the architects were instructed to prepare a bathing scheme.

Lord Kelvin's Jubilee.

The Corporation and the University of Glasgow have during the present week made common cause in their desire to celebrate with appropriate honours the professorial jubilee of the celebrated professor of natural philosophy. Lord Kelvin, then plain William Thomson, was appointed to the chair which he still holds in 1846, being then only twenty-two years of age. Since then his capacity for the most advanced scientific speculation and research and his powerful inventive genius have made his name and reputation world-wide. Probably to the general public his fame is most closely associated with the successful laying of the Atlantic cable, upon returning from which in 1866 he received the honour of knighthood. He was raised to the peerage as Baron Kelvin of Largs in 1892. The list of academic and other honours conferred upon him would fill a column or more; it is sufficient to mention that in 1871 he was President of the British Association, and that from 1890 to 1895 he occupied the chair of the Royal Society. It is no wonder that both town and gown should unite to mark in a becoming manner so interesting an event as the jubilee of so renowned a professor. Upwards of 200 delegates, representing British and foreign universities and learned societies, are at present the guests of the University, and congratulatory telegrams are pouring in from all parts of the globe. Yesterday the local jubilee committee sent their congratulations to Lord Kelvin by a cable message passing over the Anglo-American telegraph system, thus traversing a distance of 20,000 miles. The time occupied was seven and a-half minutes. In the evening the University gave a conversazione in the Bute Hall, the guests, numbering fully 2500, being received by the professors and passing on to offer their congratulations to Lord and Lady Kelvin. The exhibits included specimens of Lord Kelvin's numerous inventions and the diplomas, medals, addresses, &c., presented to him by various scientific and other learned societies. The various submarine telegraph companies had wires laid on to the Bute Hall and numerous telegrams were received and despatched during the evening. At the close of the conversazione the students held a "Gaudeamus" in the Union, and welcomed various foreign delegates in true undergraduate fashion. This morning was devoted to the presentation of addresses to Lord Kelvin and to the conferring of various honorary degrees. Lord Kelvin himself was "capped" LL.D., the cap being placed on his head by the senior professor, Dr. Gairdner. Amongst other messages received was a special letter of congratulation to Lord Kelvin from the Prince of Wales. To-night a banquet is to be given by the Corporation, and to-morrow there are to be excursions down the Firth of Clyde.

Medical Resignations.

Dr. James Stirton has retired from the position of physician for diseases of women in the Glasgow Royal Infirmary. Dr. Duncan Macartney has resigned his appointment as one of the surgeons to the Glasgow Training Home for Nurses.

Sudden Death of a Medical Man.

Dr. George R. Allan of Glasgow was found dead in his consulting-room chair on the morning of the 13th inst. He had been in his usual good health and entirely without cause for complaint, and was, indeed, proceeding with his usual daily professional duties. It is understood that the cause of death has been determined to have been disease of the coronary arteries, leading to degeneration of the cardiac muscle. Dr. Allan was one of the physicians to the Glasgow Hospital for Diseases Peculiar to Women. He was much respected and undoubtedly possessed the goodwill of all his professional brethren.

Enteric Fever at Kirkcaldy.

The spread of enteric fever in Kirkcaldy is exciting some alarm. The cases notified now exceed 100, and the local hospital being full it has been necessary to fit up one of the public schools for the reception of patients. Dr. Littlejohn has instituted an inquiry on behalf of the Local Government Board.

A Geological Excursion

A geological excursion from Aberdeen to Penrith, Cumberland, will take place next month. The party will leave Aberdeen on Monday, July 20th, and under the guidance of Professor Alleyne Nicholson (natural history), University of Aberdeen, visit the most interesting localities in the Lake District, returning on Saturday, July 25th.

Aberdeen University Court.

At the last meeting of this body regulations for the lectureship in Comparative Psychology under Dr. William Anderson's bequest were fixed. There is to be an annual honours course of not fewer than fifty lectures; the lectureship is to be tenable for five years; the appointment is to date from Sept. 15th next; the lecturer is to receive a free income of bequest (£350 per annum); and a fee of £3 3*s.* is to be charged for the course. An appointment will be made at the next meeting. It was reported that arrangements had been made for instruction of women in all medical subjects in mixed classes, but that in certain classes separate provision (covering a few lectures) would have to be made for the ladies. In surgery there will be "mixed systematic class, but women to be excluded from certain limited parts of the course." Principal Sir W. D. Geddes called attention to the throwing wide open of the doors of the university medical classes and the provision now made for the graduation of women. Professor Stephenson (Midwifery) observed that Aberdeen was the only university where ladies could enter and have the full privileges as enjoyed by male students. The Universities Commission have declined to sanction the imposition of an annual fee of 5*s.* upon students for the maintenance of a students' union, recreation ground, and similar purposes.

June 16th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Army Medical Deadlock.

SINCE the date of my allusion to the above matter last week considerable interest has been aroused in public as well as in medical circles here by a series of letters which have appeared in all the morning papers in reference to the subject. Sir Thornley Stoker, Professor Cunningham, and Professor Ball of Trinity College, Professor Heuston of the Royal College of Surgeons in Ireland, and Professor Birmingham of the (Roman) Catholic University, claim to write as responsible representatives of the medical schools of Dublin, and are unanimous in condemning the problematical efforts of some individual supposed to be connected with medical teaching in Dublin, "to bargain," as has been hinted, "with the War Office in reference to examinerships in such a manner as to hinder the promulgation of the new warrant." The writers say: "If it be true that individual effort is being directed in the manner that is feared it is not necessary to characterise the want of judgment, or worse, that prompt it." Is there, however, any real truth in the rumour? It seems more than doubtful. Professor Heuston, many of whose former pupils are to be found in the ranks of the Army Medical Service, states that "he cannot hear of a single candidate being prepared in Dublin for the coming examination." They doubtless hold back in expectation of the new warrant, which, as was remarked in THE LANCET of last week, may not be very long delayed, seeing that Lord Lansdowne is the present War Minister, that we have a new

Digitized by Google

Commander-in-Chief, and a newly appointed Director-General.

The Connswater River.

The condition of this river, which is in the eastern side of the city of Belfast, is at present the subject of considerable public discussion. This stream, alongside of which 2500 operatives are employed daily, is flanked on both banks by factories and receives sewerage matters both from the rural and city sides. The smell from it at present is intolerable, and the Board of Guardians some time ago spent £12,000 for the purpose of abating the nuisance caused by the river outside the city. The Board of Guardians are inclined to think the major amount of the nuisance now comes from the city side, and they passed a resolution on June 9th at their meeting, calling upon the public health committee to take such immediate steps as will prevent the discharge of offensive matter into the river from the city side. The most likely way out of the difficulty would be for the harbour commissioners, the Corporation, and the Board of Guardians to take joint action to stop the nuisance occasioned by this stream. At the public health committee of the corporation the executive sanitary officer reported on June 11th that the nuisance at the Connswater arises from three causes—the discharge of sewage spirit wash (from the distillery there) and large quantities of hot water into the river; these discharges, the present hot weather, and the extent of the mudbank at low tide being sufficient to account for the present insanitary state of the river. Communications are to be made to the guardians, the Rope Works Company, and the Distillery Company to bring about a more desirable state of affairs.

The Training of Imbecile Children.

A memorial and resolution on this subject has been recently approved by the Armagh Lunatic Asylum Board, and they directed that it should be forwarded to the Lord-Lieutenant and to all the asylum governors in Ireland requesting their coöperation. The memorial points out that there is no public institution in Ireland for the training and education of idiot and imbecile children. By the census of 1891 there were 6245 idiots and imbeciles, of whom 996 were in lunatic asylums, 1170 in workhouses, and 4079 were at large. In England there are three and in Scotland two institutions for the training and education of imbecile children. Workhouses are the only public institutions in Ireland where pauper idiot children can be sent, and these places are quite unfitted for their proper training and care. It was further pointed out that differences have recently arisen between Poor-law guardians and asylum governors as to their responsibilities for the care of pauper idiots. The Lord-Lieutenant was asked to cause inquiry to be made to define more clearly with whom lies the responsibility and to direct steps to be taken to make provision for the treatment of idiot children in a separate institution.

The New Derry Lunatic Asylum.

The board of control in Dublin has written to the governors of the Derry Asylum informing them that the time has arrived for considering the preliminary arrangements which it is necessary to make for building a new asylum at Gransha. A deputation from the board (consisting of the inspectors and the consulting architect) are to have a conference with the asylum governors on July 9th with a view to consider the arrangements which it is necessary to make.

The Proposed Sewage Scheme for Portadown.

There seems to be great difficulty in planning a sewerage scheme for Portadown. The town commissioners, who have had the matter under consideration for some time, were compelled to abandon a scheme they submitted owing to certain ratepayers objecting to the sewage being drained into the River Bann, which is contrary to the provisions of the River Pollutions Act. Recently they decided to empty the sewage into the Corcrain River, and against this plan a petition, signed by 500 ratepayers, has been forwarded to the Local Government Board.

Lord Kelvin's Jubilee.

The jubilee celebrations this week in Glasgow in Lord Kelvin's honour have caused the greatest satisfaction in Belfast, where the distinguished physicist was born, in College-square in 1824, his father, Dr. James Thomson, being at the time professor of mathematics in the Belfast College. Lord Kelvin's father was descended from a family of Scottish farmers who settled in Ulster, and he was born on a small farm at Ballynahinch, in co. Down. He became a teacher near his birthplace and taught during the summer at home, while in winter he studied at Glasgow. After graduating he received an appointment in Belfast and soon afterwards married. He had a family of five sons and three daughters. One of the sons was the future Lord Kelvin, who was eight years old when his father was appointed Professor of Mathematics in Glasgow University. Another brother of Lord Kelvin, Dr. James Thomson, was Professor of Engineering in Belfast Queen's College before being removed to the same post in Glasgow. "Thomson's Arithmetic," a book formerly much used in Ulster, was written by Lord Kelvin's father, and Professor James Thomson was the author of numerous original papers on the currents of atmospheric circulation, &c. President Hamilton and Professor Purser, D.Sc., represented Queen's College, Belfast, at Lord Kelvin's jubilee.

June 17th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Foreign Students in France and Protectionist Measures.

THE tide of *chauvinisme* still flows in a steady and strong stream, and culminated the other day in an interpellation at the Chamber of Deputies, the spokesman being no less a personage than Professor Lannelongue, who is a member of that sapient assembly. The appended cutting will inform the readers of THE LANCET how the question now stands:—

"Dans la séance d'hier de la Chambre des Députés, à la suite d'une question qui lui a été adressée par M. G. Berry à propos des étudiants en médecine étrangers, le ministre de l'instruction publique a fait une réponse conçue en ce sens:

"La loi du 30 Novembre, 1892, sur l'exercice de la médecine en France ayant donné lieu à quelques abus en ce qui concerne l'obtention du diplôme de docteur en médecine par des étudiants étrangers, le gouvernement a pris certaines mesures pour y remédier. Toutefois, il importe de respecter les conventions internationales relatives à cette question.

"On compte actuellement dans les facultés de médecine de France 1054 étudiants étrangers, soit 12 pour cent du nombre total des étudiants en médecine. La majeure partie de ces étudiants étrangers appartiennent à la Russie, à la Roumanie, à la Bulgarie, et à la Grèce, c'est-à-dire à des pays nés plus récemment que le nôtre soit à la vie politique, soit à la vie scientifique. La présence de ces étrangers dans les facultés françaises est la preuve évidente de la hauteur de notre enseignement. Leur fermer la porte de nos établissements serait une faute, car la plupart ne viennent chez nous que pour y étudier et retournent ensuite dans leur pays une fois leurs études terminées.

"Le ministre annonce en terminant qu'il étudie le moyen de délivrer aux étudiants étrangers non pourvus des titres français et ayant terminé leurs études médicales un diplôme spécial de docteur en médecine ne donnant pas le droit de pratiquer en France.

"Après cette réponse du ministre, la question, sur la demande de M. Lannelongue, est transformée en interpellation, et finalement la Chambre adopte un ordre du jour, accepté par le gouvernement, 'invitant le ministre de l'instruction publique à déposer un projet de loi sur la situation des médecins et des étudiants étrangers en France.'"

Let us hope that the matter is buried for the present, and that France will after due reflection deem it wise not to insist on a measure which will have the effect of driving remunerative British and American visitors into Italy, whose Government is far too sensible to do other than welcome foreign medical men and the patients they bring in their train.

Vulvo-vaginitis of Infants.

Considerable divergence of opinion existing as to the true nature of the above-named disease so frequently met with in young female children M. Veillon and M. Hallé have recently made researches thereon in the laboratory of Professor Grancher, the subjects being twenty-one children affected with a vaginal discharge and six apparently healthy children. The clinical study of these cases has led the writers[1] to divide vulvo-vaginitis into two groups. The first variety affects neglected children suffering simultaneously from skin diseases such as impetigo, phthiriasis, and eczema. Here we find in the genito-crural fold, around the clitoridean prepuce and behind the inferior commissure of the vulva, a whitish smegma mixed with a small quantity of turbid serous discharge. On separating the labia majora no secretion is observed to escape from the vulva even when efforts at defecation are made. This slight discharge does not stiffen linen and disappears readily under ordinary cleansing treatment. In the second and most

[1] Archives de Médecine Experimentale et d'Anatomie Pathologique, May, 1896.

Digitized by Google

common category we have to deal with vulvitis accompanied by purulent discharge staining linen of a green colour. This green discharge is seen on the labia majora and around the clitoris. When the discharge is profuse the pus dries on the labia majora, the inguinal fold, and the surrounding skin as thick crusts. Separation of the labia brings to view a quantity of pus in the neighbourhood of the meatus, the edges of which are inflamed. On depressing the falciform fold that conceals the vaginal orifice the hymen is seen to be red and inflamed. Often a drop of pus obstructs the vaginal entrance; if not, efforts at defecation suffice to expel a certain quantity of green, viscid pus resembling that of acute gonorrhœa. This discharge is persistent, simple measures of cleanliness being incapable of curing it. It is strange, however, that the children suffering from this variety of vulvo-vaginitis utter no complaint. The majority of these latter cases are undoubtedly of gonorrhœal origin, M. Veillon and M. Hallé having almost invariably discovered in the pus Neisser's gonococcus. The usual complications of gonorrhœa may therefore ensue, and appropriate treatment is necessary. In very acute cases the microbe was found in the pure state. In other instances it was associated with the non-virulent micro-organisms normally found in the vagina of young female children. These are, according to the writers, in their order of frequency, the common pseudo-diphtheria bacillus, the club-shaped pseudo-diphtheria bacillus of Weeks, the non-pathogenic streptococcus, and the staphylococcus epidermidis albus. The existence in the vagina in health as well as under pathological conditions of organisms liable to be confounded with Löffler's true diphtheria bacillus should not be lost sight of if an erroneous diagnosis of vulvar diphtheria is to be avoided. The presence of the gonococcus in a vulvar discharge occurring in a child does not necessarily mean that the patient has been subjected to violence, the infection being generally indirect. I myself had occasion to report on a case of vulvitis where the only alterations discernible were a slight swelling and the presence of the smegma referred to above. The mother was persuaded that her child had been tampered with by a man who had been previously convicted of such an offence.

June 17th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Direct Observation by means of the "x" Rays.

THE striking results of Professor Buka which I reported in my last letter[1] have been confirmed by Dr. Levy in a paper read before the Berlin Physiological Society. Dr. Levy, in collaboration with Professor Grunmach, has, moreover, extended the method of direct observation to pathological conditions of the internal organs. In a patient who formerly suffered from pulmonary tuberculosis but had now apparently recovered the calcified tubercles became perceptible as dark-coloured areas in the apices of the lungs, and in a case of arterio-sclerosis the calcified coronary arteries appeared as black stripes in the shadow cast on the screen by the heart.

A New Hypnotic.

In a paper read before the Verein für Innere Medicin, Professor Jolly has given an account of a new hypnotic called pellotin, which is not prepared by chemical synthesis, like the other sleep-inducing medicaments of the present day, but is an alkaloid discovered in a species of Mexican cactus called anhalonium. The natives of Mexico are reported to swallow slices of this plant to which they give the name of "Pellote," and Dr. Hefter of Leipsig has now succeeded in isolating its soporific alkaloid. Pellotin itself is not soluble in water, but its hydrochlorate is extremely soluble. Its physiological action was first tried on frogs and then on mammals, which very soon became unable to stand or perform spontaneous movements, and shortly afterwards an increase of the reflexes was observed, followed by tetanic convulsions. This action of the drug on animals was not identical with that which Dr. Hefter observed in himself, for after taking five centigrammes (three quarters of a grain), he became very drowsy and ultimately fell asleep. The drug was then given by Professor Jolly to a number of patients in the neurological wards of the Charité Hospital in Berlin. The first case was that of a man suffering from alcoholic neuritis who, after an injection of four centigrammes became very drowsy, and one hour afterwards he fell into a sleep which lasted for four hours. Dr. Hefter had observed in himself a diminished pulse-rate and the same symptom was perceptible in this patient, during the first hour of whose sleep the pulse fell to 56 per minute, rising again to 76 before the man awoke. Another patient with multiple sclerosis took five centigrammes during the afternoon, and after half an hour he also slept soundly for several hours. Similar results were obtained in a series of other cases. In patients suffering from tabes the soporific action was equally satisfactory, but the pains returned after they woke. In delirium tremens the effect was less prompt; in one instance twelve centigrammes (equal to one and three-quarter grain) were needed only to tranquillise an excited patient, but no sleep ensued. In twenty cases of different kinds the remedy was given as a hypnotic in the evening. Two centigrammes had no effect, but from four to six were efficacious in producing sleep and no injurious consequences of any kind were observed. Some patients complained of giddiness and declined to take the medicine, but the greater number did not suffer in this way. Professor Jolly says that six centigrammes (equal to about one grain) of pellotin are equal to one gramme (equal to 15½ grains) of trional, or two grammes (equal to 31 grains) of hydrate of chloral. The number of cases is as yet too small to justify the formation of a definite opinion as to the new remedy, but it undoubtedly deserves further trial.

The Sequel of the Langerhans Case.

In THE LANCET of June 6th (p. 1596) I gave an account of the microscopical and chemical analysis of the antitoxin administered to the child of Professor Langerhans, and after a long delay the official report of the post-mortem examination has been published in the *Berliner Klinische Wochenschrift*. The examination was performed by Professor Strassmann and Dr. Mittenzweig, medical officers to the Berlin law courts. Previously to the fatal injection the child had taken his dinner, followed shortly afterwards by some milk and cake. Death took place during a severe fit of coughing, and the necropsy showed that the trachea and bronchi were entirely filled by a grey substance, which by microscopical examination was proved to consist of particles of food, a good deal of the same being still present in the stomach. The uvula was swollen. The medical experts, therefore, declare that the child died from suffocation. They are of opinion that the boy vomited after the injection; and being in a fainting state from the pain of the injection, he was not able to get rid of the vomited matter, but drew it into his larynx in the act of inspiration. They did not find any embolism of air in the pulmonary artery, as was suggested, nor was there any confirmation of the opinion that death had occurred from syncope, and they advised the court not to hold anyone responsible for the child's death. According to the statement of the Control Office the serum was of normal quality and the injection was in their opinion justified by the present state of medical knowledge. The matter is thus at last entirely cleared up, and the unfortunate father will probably now regret that he unnecessarily alarmed the public and aroused a prejudice against a mode of treatment which has proved a blessing to a great many sufferers.

June 16th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

A Study in Social Criminology.

IN spite of the "Index Expurgatorius" the nexus between physical organisation and moral responsibility attracts successive relays of students in Italy which, for the attention it has bestowed on it throughout, may almost claim the subject as its own. The last and not the least penetrating and practical of the studies in question is that of Signor G. Ciraolo—a barrister by profession and a physiologist by predilection—whose volume entitled "Delitti Femminili a Napoli: Studio di Sociologia Criminale" (Milan: Kantorowicz, 1896) exemplifies skilfully and effectively the advantages of a legal supplemented by a purely scientific training. His researches were chiefly pursued in Naples—in some respects the most depraved city in Europe, rich in types of racial

legeneracy and prolific in the crimes to which each type is prone. The book abounds in illustrative examples of these—narrated with the analytic power of a pleader and the dramatic force of an artist; and if the author sins occasionally in too facile resort to generalisation, which sometimes indeed looks rather like a trick, he may plead in excuse that his classifications are provisional only—meant to aid the student in grasping an otherwise bewildering wealth of detail. With his qualification the reader will find much in the book that is suggestive, more that is interesting, and most of all that it behoves the student of social science to know, whether it conflicts or harmonises with his preconceived notions.

Balneo-Therapeutics.

The season of hydrological congresses, as it may be called, began on Sunday, the 14th inst., at the Bagni di Porretta, that well-known thermal resort on the Milan-Bologna-Florence line of railway. These gatherings increase annually in importance for the profession as well as the public, concentrating a larger amount of attention on Italy's undeveloped resources in natural mineral waters and showing the leeway she has yet to make if she is to compete advantageously with the frequently less rich but almost invariably better appointed establishments beyond the Alps.

The New Sanitary Works at Naples.

"See Naples and die," says the proverb—true till quite lately in a sanitary even more than in an artistic sense. The fairest city of Southern Europe, bears[1] "the reproach of concentrating in itself nearly every vice of which the sanitary reformer can take cognisance, whether as to water-supply, as to drainage, or as to dwelling-house accommodation." But in the following week you reported at length King Humbert's memorable visit to the work of sanitary rehabilitation already begun, and described the elaborate operations then in progress for supplying the city with pure "acqua potabile," with adequate drains, and with wholesome and attractive dwellings. Since that day, in spite of interruptions and postponements, without which no Italian undertaking can proceed, the beneficent work has been carried forward and another mighty advance in the right direction has scored on the 7th inst., when, in presence of the authorities—legislative, municipal, and sanitary—gathered round the colossal "vasca di raccolta" excavated under Posilipo, was inaugurated the new network for draining the upper and central quarters of the city. This splendid achievement in sanitary construction was primarily the design of the philanthropic citizen Nicola Amore, Syndic of Naples, who did not survive to witness the realisation of his dream, while the engineer Minozzi, guided by the municipal engineer, Gaetano Bruno, conducted it to completion. By it all the effete matters of the city—the refuse and sewage of every kind—are drawn away and from the "vasca di raccolta" (tank of collection), under Posilipo, are conveyed far beyond the suburbs to the desert shore of Cuma. Upper and middle Naples are the quarters thus relieved by the network which runs its channels throughout all the city, the lower quarters of Porto, Pendino, and Mercato excepted. Converging in the main collectors, they all meet finally in the "vasca" aforementioned, whence the "liquid foulness" drags its slow length along, a distance of nearly eight miles, to disembogue at Cuma. At the ceremony of inauguration a brief but lucid description of the works was given by the engineer, Bruno, after which the Royal Commissioner made a short address, and then with three blasts of the trumpet the signal was given to let loose the pent-up sewage. In ten minutes the "fiumana cloacale" (the river of Cloacina) was in motion, carrying with it the *materies* of those maladies which for centuries have put Naples in evil odour even among Mediterranean seaports, and restoring her (let it be hoped) to her earlier and purer self when she was the resort of whatever was most refined and civilised in Imperial Rome.

Italian Surgery at Berlin.

One of the collateral benefits to be derived from congresses is the opportunity they afford the foreign delegates of comparing other institutions and other methods with their own—a benefit of which Italian teachers and consultants have freely and cordially availed themselves. At the jubilee gathering of surgeons lately held in Berlin, Italy was mainly represented by Professor Bottini of Pavia and Professor Antona of Naples, names familiar to the profession in the British Isles, particularly that of Bottini for his original monograph[2] on Cavernous Angioma of the Cheek; its Surgical Cure. These eminent clinicians have just conveyed to their countrymen, through the *Corriere* of Milan, their impressions of the Teutonic as compared with the Italian schools, and, so far as teaching is concerned, especially clinical teaching, the note they strike is one of self-humiliation, the prelude (it is to be hoped) of speedy and root-and-branch reform. Take hospitals as an instance in point. At Heidelberg Professor Czerny's clinique includes 300 students and 220 beds. At Naples the analogous clinique of Professor Gallozzi numbers 2000 students and only thirty beds. The other two parallel cliniques at Heidelberg, with some sixty students, have over 200 beds, and at Naples Professor d'Antona, addressing about 500 students, has for purposes of clinical illustration not more than twenty beds. Even in more modest schools the superiority of Germany to her Latin sister is not less overwhelming. Göttingen, in the surgical clinique of Professor Franz König, has 130 beds for some eighty students, and Professor Bottini, in the school of Scarpa and de' Porta, gives lectures to 250 students of the fifth and sixth course with but thirty-seven beds. *Mancanza di quattrini* (want of money), which in Italy explains most things, is not wholly responsible for the clinical inadequacy of her schools. For one thing, such funds as she possesses are too often misapplied, marble and granite absorbing in hospital construction the resources which should be expended on the multiplication of wards and their appropriate equipment. In Berlin the Urban Hospital accommodates 600 patients provided with every hygienic and clinical requisite, and all for two and a half million lire (£100,000). At Genoa, on the other hand, the Galliera Hospital, at a cost of seventeen millions (£680,000), is a splendid palace with but 200 beds "esposti," says Professor Bottini, "da un lato ai venti del mare, dall' altro ai venticelli ..... delle latrine" (exposed on one side to the sea breezes, on the other to the fumes of the ..... privies). Even the Policlinico at Rome (the creation of Baccelli) is not exempt from the criticism that on its fine artistic *ensemble* there has been lavished an amount of money which should have had its appropriate destination in wards and other clinical appointments worthy of the chief hospital of the capital of United Italy. It is to be hoped that Professor Bottini will follow up his "confronti" (contrasts) between German and Italian medical education, if only to convince the rather apathetic public, and thereafter the legislature, that exceptionally fine medical aptitudes and the highest aspirations towards professional efficiency will not attain their end without the object-lessons and the experience which Germany, and still more the British Empire, afford in their hospitals.

The Mediterranean Squadron in Italian Waters.

THE LANCET is known and appreciated in the British navy for its vindication of the best interests of the service, primarily, of course, the medical and sanitary interests, and secondarily those interests indissolubly associated with the prestige of the British flag. From foreign capitals (which might have been expected to have been better inspired) there have returned to us the messages of correspondents representing them in Italian seaports, messages reflecting on the conduct of the visitors from the Mediterranean squadron. The *Popolo Romano*, an authoritative Roman journal well entitled to speak for the name it bears, in drawing attention to these messages, takes occasion to characterise them as the "solite esaggerazioni di corrispondenti" (the usual exaggerations of correspondents), and gives a very different impression of the conduct in question as produced in Rome especially. That impression, I may add from personal knowledge, is shared by Italians of all ranks and creeds, from the humbler strata of society up to the Quirinal and the Vatican.

The Italian Red Cross.

By Royal decree there has just been nominated a commission to settle, if possible, in an affirmative sense, the following proposals: (1) the admission of military men, on unlimited leave (*congedo illimitato*), into the *personnel* of the Red Cross; (2) that the said *personnel* shall have a military discipline and jurisdiction; (3) that the same *personnel* shall be entitled to pensions on the ground of wounds or infirmities incurred in time of war or even in time of peace on occasions of exercises (autumn manœuvres and such like); (4) that measures be adopted to prevent the abuse of the

emblem and the name of the Red Cross; and (5) that the various societies of aid to the sick and wounded shall, in time of war, be dependent on the Red Cross Association. The commission is a strong one, including a highly competent representative of the medical arm.

June 15th.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The Coronation Festivities and the Disaster at the Popular Fête.

THE series of elaborate festivities with which Russia has marked the advent to the throne of her new Emperor are now drawing to a close. As all the world by this time knows, the State entry into Moscow on May 9th (21st) and the Coronation itself on the 14th (26th) have been followed by nearly a fortnight's general rejoicing. The ancient city has decked herself in all her best, and with street decorations and illuminations of quite extraordinary beauty has made a brave show, and has provided such a background for the pageants that have been enacted within her walls as probably few other cities could provide. With one exception the whole series of ceremonials, the more popular of which have been witnessed by hundreds of thousands of spectators, Russian and foreign, have passed without serious accident. It was inevitable that many of these ceremonials should have caused extreme fatigue to the principal actors. The most trying of all was the Coronation service itself. A service lasting some three hours was followed by the formal reception of congratulations and an Imperial banquet in the old dining hall of the Kremlin Palace. When it is remembered that the Emperor and Empress had been fasting since the previous midnight, in obedience to the injunctions of the Church, and that the banqueting-hall was not reached until nearly three o'clock; when it is further remembered that they had for many hours been standing under the enormous weight of the Imperial robes of gold tissue and ermine, it is scarcely surprising that their Majesties showed clear signs of physical exhaustion, to which the mental strain and the extraordinarily impressive and significant nature of the ceremonial they had passed through must have contributed in no slight degree. Fortunately, however, no serious results followed, and the Emperor and Empress, though looking tired, appear to be in excellent health and have borne their share in the never-ending festivities of the past fortnight with a quiet dignity and grace which have delighted everybody. The one exception to the success of all these *fêtes*, to which I have already referred, was, unfortunately, a very terrible one. It is not easy yet to write quite calmly about the catastrophe of last Saturday, details of which will have already appeared in the English papers. The dreadful sight in the field itself, which in parts was literally heaped with dead bodies, the gruesome string of firemen's carts laden with corpses which met one on the way to the *fête*, and were the first intimation one had of any disaster having occurred, and subsequently the painful scenes at the cemetery when the victims were buried, of necessity made such an impression upon all who beheld these scenes as to for the moment blot out the recollection of the previous scenes of brilliant gaiety and to replace the bright sunshine with a most hideous and depressing gloom. It is perhaps too early yet to apportion blame for this disaster, but it is clear to the most superficial observer that "some one had blundered." To build a long string of wooden huts (from which the Emperor's presents of an enamelled mug and a handkerchief full of eatables were to be distributed to the people) within a stone's throw of a long ditch, the bottom of which was dug out into deep holes from eight to twelve feet deep,—to do this when it was expected that at least 400,000 peasants would flock to the field from Moscow, and consequently have to cross this ditch, which was on the city side of the field, was to court disaster. When at about seven o'clock in the morning a sudden rush was made towards the huts, and a clamour arose that the gifts should be given out, what might have been foreseen happened. Those near the ditch fell into it. Hundreds of thousands pressed on over them. For those who fell to rise again was impossible, and it was even impossible for others to help them. Peasants themselves told me they could feel they were trampling over a field of struggling human beings, but so tightly were they themselves packed that they were unable to move a finger. A second death-trap existed in an old disused well, which had been dug in 1891 for the French Exhibition, which was held on the same plain. It had been boarded over and the boards covered with sand, but the boards were not strong enough to bear the dense crowds, and some half hundred unfortunate peasants met with a horrible death in this pit. The total number of victims is between 2500 and 3000. The terrible disaster is doubly regrettable, not only for itself, but for the fact that it has led many to blame those who are in no sense to blame. The Emperor himself is held responsible by the common people, who are accustomed to lay everything "upon the king." Even a better educated class are murmuring loudly and deeply, and the impression the disaster has made will take a very long time to efface, if, indeed, it will ever be effaced. It is the more unfortunate as the police and military arrangements at all the other functions at some of which the crowds must have been nearly as great as those of last Saturday, have been admirable, and the good nature on both sides quite striking. But for this one dreadful exception the festivities marking the Coronation of Nicholas II., for the success of which everything, the weather included, seemed to have coöperated, would have been one unbroken memory of delight and enjoyment.

The International Medical Congress.

The programmes of the different sections are now in preparation, and the letters of invitation to those who will be asked to read papers are being printed. All the foreign committees have now been formed with the exception of the English. The executive committee have invited Sir James Paget to undertake the formation of the English committee, but his reply has not yet been received.

Moscow, May 24th (June 5th).

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Chronic Endometritis as a Precursor of Carcinoma Uteri.

DR. BACKER, after having examined the notes of 78 cases of uterine cancer which have been under the care of Professor Kézmarszky at the Budapest I Maternity, was able to infer that women suffering from chronic endometritis were specially liable to contract carcinoma of the uterus. He pointed out that the occurrence of this disease was apparently in connexion with such forms of chronic endometritis as could most frequently be traced to troubles of the puerperium. In corroboration of this view he draws attention to the well-known facts that uterine cancer is more frequent with women who had borne children previously, and that it is often to be found among the poor, who are more likely to neglect uterine troubles. Moreover, uterine catarrhs of old standing figure nearly always in the history of the case. A good lesson to be derived from Dr. Bäcker's able paper is that chronic endometritis should never be neglected, as its thorough and effective treatment might lead to the prevention of the dreaded disease.

Public Health in Hungary during 1893.

The official annual report on public health has just been issued by the Home Office. It shows that the condition of the country from a health point of view was satisfactory as compared with former years. In 1895 162,660 men suffered from zymotic diseases, of whom 15·7 per cent. died; while in 1894 166,424 infectious cases had been notified, with a death-rate of 22 per cent. This amelioration was due partly to the steady spread of sanitary measures and partly to the improved methods of combating the diseases. An increase of morbidity and mortality from small-pox must be noted. It is very interesting to record that of 4762 vaccinated persons who were attacked by small-pox 548 (11·5 per cent.) died, whereas of 2212 non-vaccinated persons 923 (47·7 per cent.) succumbed to the disease. The number of vaccinations exceeded by 30,448 the total of the preceding year, this surplus being chiefly due to re-vaccination. Vaccination was generally effected with fresh animal lymph, humanised lymph having been used in 7·2 per cent. only. As regards diphtheria the average mortality showed 35·5 per cent., against 53·1 per cent. in 1894 and 43·04 per cent. in 1893. An institution for the production of antitoxic serum has been created under the direction of Professor Preisz and yielded 350,000 doses of serum. Serum of Hungarian and foreign make has been distributed gratuitously among the poorer

Digitized by Google

class and consequently employed on a large scale. The results of this treatment obtained throughout the whole country are not ready yet for publication, but will be shortly.

The Housing of the Working Classes.

This question, which has been much neglected in the Hungarian metropolis, was recently made the subject of careful study and consideration by Dr. J. Farkas. He showed the inefficacy of the spare measures which had been adopted by the State Government and the town council of Budapest in comparing the alleged results with those obtained in Great Britain, France, Belgium, and the United States. His paper gives a full account of the methods which ought to be employed with a view of improving the state of affairs and is well worthy of perusal by those concerned.

June 9th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Adelaide Medical School and Hospital.

MATTERS have reached a climax in the affairs of the Adelaide Medical School and Hospital and the result is that the students are betaking themselves to Sydney and Melbourne for the clinical instruction which they despair of getting in their own city. First of all the South Australian Government withdrew the annual grant to the school and now the honorary staff at the hospital has resigned in a body so that no clinical teaching is possible. The work at the hospital is carried on by the resident staff with some assistance from a few practitioners who are in the Government service. Patients naturally refuse to go into the hospital and such as are able are leaving. It was hoped that some arrangement would be possible and matters might be smoothed over, so that the members of the honorary staff could withdraw their resignation, but the Government has remained obdurate and is endeavouring to meet the difficulty as far as the hospital is concerned by advertising for a resident surgeon at £400 per annum, who is to be capable of undertaking all the surgical and gynæcological work, and a resident medical officer at £300. No one in South Australia will apply, the whole profession supporting the staff, but the Government hopes that in some other country, where the facts are not so well known, some practitioners may be found so destitute of *esprit de corps* as to take these appointments. All right-thinking members of the profession in the colonies now regard the differences between the Government and the staff—originating in a small question of nursing discipline, as already described—as a fight of might against right, and trust that whatever may be thought as to the expediency of the somewhat Quixotic action of the members of the staff in the first instance they will now receive the support of the profession universally in their self-sacrificing struggle against the ignorant and insulting tyranny of the Government.

Women as Resident Medical Officers at the Melbourne Hospital.

According to the rules of the Melbourne Hospital the resident medical officers are appointed annually from the students of the hospital, according to their place in the class lists of the Melbourne University. A few years ago a woman was among the first in the class lists and applied for the position but was ruled ineligible as she was not a full student of the hospital, having done some of her clinical work at the Alfred Hospital. This year two ladies, Miss Gamble and Miss Greig, are eligible according to the rule, and, notwithstanding much opposition, have just been appointed to the positions. The honorary staff, strange to say, was not consulted in the matter. The new medical officers will certainly find plenty of difficulties, as many of the honorary staff, the matron and most of the nurses, and the students are opposed to them. Miss Greig has been placed in charge of the casualty room, and had a lively experience the first night she was on duty, treating cases of alcoholism and assault, &c., and many doubt whether she will be able to stand the strain of the position under the circumstances.

Prevalence of Typhoid Fever: the Cold Bath Treatment.

Typhoid fever continues to be very prevalent both in Sydney and Melbourne. In the former metropolis the cases have chiefly occurred in the thickly populated but low-lying districts which are not yet sewered, while those parts connected with the sewerage have escaped. MR. Kendall, medical officer to the Sydney Water and Sewerage Board, attributes the outbreak in part to the fact that in the districts where it is most rife the houses are built on made soil contaminated by leakage from cesspits and pan-closets; in addition the rainfall has decreased, only amounting to nine inches as compared with sixteen inches for the corresponding quarter of last year, and the average range of temperature has been much higher. The suburbs along the Illawarra line, which are very low-lying, with no drainage, are most affected. In Melbourne sewerage work is in progress, and many attribute the prevalence of typhoid fever to the stirring up of the contaminated soil by the excavations for the drains. Public attention has been forcibly directed to the cold bath treatment of typhoid fever by a correspondence on the subject in the Melbourne daily press, a correspondence deprecated by many as affording a means of cheap advertisement to such practitioners as chose to make use of it and as also likely to do more harm than good from a public point of view. The physicians of the Melbourne Hospital in particular have been blamed for not using the Brand method more largely, and their results have been contrasted with those obtained in the Brisbane Hospital where it is used in every case. It has been pointed out, in reply, that the comparison is unfair, the Melbourne Hospital receiving a large number of patients in the last stages of the disease, when death is almost inevitable under any treatment and the Brand method is inapplicable. It has also been stated that the improvement in the mortality at Brisbane Hospital since the introduction of the bath treatment cannot fairly be said to be due entirely to the use of that method, as the mortality in private cases not so treated has also improved, and the type of the disease has been much milder since 1887, when assisted immigration ceased, the acclimatised population apparently suffering much less severely than did the newly arrived immigrants.

Annual Meeting of the New South Wales Branch of the British Medical Association.

The annual meeting of the New South Wales Branch of the British Medical Association was held on March 27th, and the following were elected as office-bearers for the ensuing year. President: Dr. Sydney Jones. Vice-President: Mr. Clubbe. Councillors: Dr. Thring, Dr. Knaggs, Dr. Jenkins, Dr. Scot-Skirving, Dr. Crago, Dr. Worrall, Dr. Coutie, Dr. Quaife, Dr. Fiaschi, Dr. Chisholm, Mr. Newmarch, and Dr. Mullins. The retiring President, Dr. E. J. Jenkins, read an address, in which, after feelingly alluding to the death of Dr. Huxtable, the late secretary of the branch, he referred to the relation of the profession to friendly and medical aid societies, and congratulated the profession in New South Wales on the successful stand it had taken. The proposal to register midwives was strongly condemned, and the proposal of Dr. Sydney Jones to establish farm hospitals in the country for cases of phthisis was warmly approved. The need for an Inebriates Act was noted and also of some means of preventing the indecent advertisements of abortionists with which the newspapers abound.

Scurvy in Infants.

From an interesting paper read before the Medical Society of Victoria by Dr. A. J. Wood it would appear that scurvy is not at all an uncommon affection of Australian children, though not always recognised as such. He records seven cases in his own practice and in most the food was either condensed milk or concentrated or sterilised milk. In one case fresh milk was given, but in a very diluted form. The prolonged heating of condensed, concentrated, and sterilised milk destroys its anti-scorbutic properties. All the cases quickly recovered when given fresh foods, fresh milk, and meat juices.

Obituary.

CHARLES PAGET BLAKE, M.D. EDIN., F.R.C.P. LOND.

WE regret to announce the death of Dr. Paget Blake, R.N., which occurred at his residence, Alverstoke Vale, St. Mary-church, on June 12th. The deceased was born at Alverstoke, Hampshire, in 1819, and was the son of Admiral G. C. Blake, naval gentleman usher to the late Prince Consort. He was educated at Bishop's Waltham School and Edinburgh University, where he graduated M.D. in 1840. In the same

Digitized by Google

year he entered the navy and as assistant-surgeon on H.M.S. *Cornwallis* served in the operations on the coast of China and up the River Yang-tse-Kiang, landing with the naval brigade at the capture of Woosung, Chappos, and Chin-Kiang-Foo, for which he received the China medal. In 1856 he retired from the navy and settled in Torquay, where he was in practice for a considerable period. He will be best remembered in Torquay for his gift of curiosities from all parts of the world to the town. He was on St. Marychurch local board and for two years had been a guardian of the poor and chairman of the Moretonhampstead Convalescent Home. He took an active interest in the various charitable and philanthropic societies of the town. He was one of the original trustees of St. John's Masonic Lodge, Torquay, of which he was one of the oldest members. In 1874 he was elected a Fellow of the Royal College of Physicians of London. The funeral took place upon June 16th.

THOMAS ALEXANDER MITCHELL, L.R.C.P., L.R.C.S. IREL.

MR. T. A. MITCHELL, who died on May 5th from the effects of a fall while running to catch a train, was a well-known practitioner at Southend, where he resided, and possessed a reputation as a skilful surgeon. He received his medical education at Dr. Steevens' Hospital, and previously to taking up his residence at Southend had for many years a large practice at Catford, near Lewisham, and was much respected by all his patients. Mr. Mitchell held several assurance appointments and under the Contagious Diseases Act, 1879–80, was surgeon for Woolwich. His contributions to medical literature included "Early Escape of Liquor Amnii," "The Growth of Hair after Death," and "Secretion of Milk in the Male," the latter appearing in the columns of THE LANCET in 1885. Always a kind-hearted and amiable man, with a strong sense of duty, the death of Mr. Mitchell in his forty-eighth year will be lamented by a large circle of friends and patients.

SIR THOMAS GALBRAITH LOGAN, K.C.B., M.D. GLASG., F.R.C.P. LOND.,

HONORARY PHYSICIAN TO THE QUEEN.

THE Army Medical Department has lost in Sir T. Galbraith Logan a former Director-General and an officer of long and distinguished service. Sir T. G. Logan died on the 11th inst. at the advanced age of eighty-seven years. He was a man of singularly kind and courteous manner and much beloved. He was the eldest son of an army surgeon and was born in 1808, educated at York and Ayr, and graduated as M.D. Glasg. He entered the Army Medical Department after taking his degree at Glasgow and was appointed an assistant surgeon in 1830. As a surgeon, which rank he obtained in 1842, he served in the Sutlej Campaign of 1845–6 with the 53rd Regiment, and was present at the affair of Buddiwal, and took part in the actions of Aliwal and Sobraon, for which he had the medal and one clasp. Appointed a Surgeon-Major in 1852 he went out to the Crimea in 1855, serving at the Siege of Sebastopol, and was present at the taking of the Quarries on June 7th, at the assault a few days later, and, as principal medical officer of the Highland Division, at the final assault on Sept. 8th. For these services he was awarded the medal with clasp, the Fifth Class of the Medjidie, and the Turkish medal. He reached the rank of Inspector-General in 1859, was Director-General of the Army Medical Department from 1867 to 1874, being created a K.C.B. (Military Division) in 1869, and was placed on the retired list in April, 1874. He had been honorary physician to the Queen from 1859, and he was a Fellow of the Royal College of Physicians of London, from 1867 and hon. Fellow of the Royal College of Surgeons in Ireland. Sir Thomas Logan, who married in 1858, was also a Fellow of the Royal Geographical Society, and on the Royal Patriotic Fund Commission. The deceased officer was a well-read man, an excellent linguist, and a very genial, pleasant companion. He had travelled a great deal and seen much of the world, and of the European continent in particular. It is recorded of him that he won a prize instituted by the officers of his regiment in a spirit of comradeship and pleasantry for never having lost his temper during a stipulated time mutually agreed upon. In spite of his personal predilections being in favour of the regimental system, of which he had such a long and pleasant experience, he became convinced that the so-called unification or general system was the right, as well as the only practicable, one for modern warfare, and he consequently became a strong advocate for the present system. His courteous bearing and manner in official life and on committees, with a strong dash of common sense, gave him a good deal of influence with those with whom he came in contact and he was almost universally and deservedly liked.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Leipsig:* Dr. O. Fischer has been appointed Extraordinary Professor of Medical Physics. Dr. E. Krückmann has been recognised as *privat-docent* in Ophthalmology.—*Prague* (German University): Dr. P. J. Pick has been promoted to the Professorship of Dermatology.—*Rome:* Dr. S. de Sanctis has been recognised as *privat-docent* in Mental Diseases, Dr. Faraci as *privat-docent* in Otology and Laryngology, and Drs. Albanese and Dutto in Physiology.—*Turin:* Dr. L. C. de Martüs has been recognised as *privat-docent* in Mental Diseases. *Vienna:* Dr. Lott has been recognised as *privat-docent* in Midwifery and Gynæcology, and Dr. Mracek as *privat-docent* in Dermatology.

MR. and MRS. LEOPOLD DE ROTHSCHILD have sent a cheque for £20 towards the charitable work of Ings House Nurses' Coöperation, 81, New Bond-street, W.

THE Nursing Exhibition at St. Martin's Town Hall was closed on Saturday evening by the presentation to Mrs. Bedford Fenwick of an album containing press notices concerning the exhibition.

ROYAL METEOROLOGICAL SOCIETY. — The last meeting of this society for the present session was held on Wednesday evening, the 17th inst., at the Institution of Civil Engineers, Westminster, Mr. E. Mawley, F.R.H.S., President, in the chair, when Mr. H. Harries read a paper on Arctic Hail and Thunderstorms.

NEUROLOGICAL SOCIETY OF LONDON.—A meeting will be held at Dr. Waller's Laboratory, Weston Lodge, 16, Grove End-road, N.W. (opposite the end of Abbey-road), on June 25th, at 8.30 P.M., when Dr. Waller will give a demonstration of the Action upon Isolated Nerve of Anæsthetics, Sedatives, and Narcotics.

AT a general court of the Governors of Addenbrooke's Hospital, Cambridge, held on Wednesday last, Professor Clifford Allbutt was elected a lecturer on clinical medicine and Sir George Humphry was elected a lecturer on clinical surgery, the object of this being to bring the medical teaching in the University into closer relations with the clinical teaching at the hospital.

LITERARY INTELLIGENCE. — Messrs. Baillière, Tindall, and Cox will publish shortly a new work on "Gout and Goutiness," by Dr. Wm. Ewart; "The Objects and Limits of Operations for Cancer," by Professor Watson Cheyne; a translation of the forthcoming "Atlas of Pathological Histology," by the leading German professors, edited by Dr. Arnold Brass; this work will be illustrated with over 1000 fresh microscopical specimens in colours, the translator being Dr. Robert A. Young of the Middlesex Hospital. They also announce Professor Jakob's "Hand Atlas of the Nervous System," translated by Dr. Collins, with seventy-eight coloured plates; and Professor Lehmann and Professor Neumann's "Hand Atlas of Bacteriology," illustrated with sixty-three coloured plates.—Messrs. P. S. King and Son, King-street, Westminster, will publish shortly, providing a sufficient number of subscribers is obtained, a general index to Hansard's Parliamentary Debates from 1830 to 1891. The plan on which the index is to be constructed is an excellent one, giving the names of speakers and the debates they took part in, together with the subjects of debates, Bills, motions, &c., with dates and numerous cross references. An exceedingly useful feature of the work will be the part of the index relating to historical declarations and phrases. The complete index will be supplied according to binding from £10 10s. to £11 10s.

Digitized by Google

MR. GEORGE STEVENS of Norton, Bury St. Edmunds, will receive for the eleventh time the vaccination grant from the Local Government Board for successful vaccination in the third district of the Stow Union.

THE annual meeting of the Association for the Oral Instruction of the Deaf and Dumb will be held at 11, Fitzroy-square, W., on Thursday, June 25th, at 3.30 P.M., when a short illustration of the system will be given and the prizes will be distributed.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—Mr. John Powell, L.R.C.P., L.R.C.S.Edin., of Barry, near Cardiff, has received from the Barry Railway ambulance class in connexion with the St. John Ambulance Association a silver-mounted walking-stick for his gratuitous services as lecturer.—Dr. George Middlemiss of Darlington has been the recipient of a handsome silver-mounted ebony walking stick, suitably inscribed, from the members of the Darlington District Class of the North-Eastern Centre of the St. John Ambulance Association, as a slight recognition of his services as the Class Instructor.

THE DIFFUSION OF SMALL-POX.—The occurrences of small-pox in and around the metropolis continue to be very trifling at the moment, and in the home counties the disease shows but little evidence of spreading. The guardians of the Maidstone Union have been led by the occurrence of small-pox on a small scale in the district to adopt a resolution to the effect that all the children attending the public and private schools in the town of Maidstone shall be examined during school hours by the public vaccinator to ascertain whether they have been vaccinated. It will be interesting to hear what the school authorities have to say to the resolution in view of the attitude taken at some other places on the same subject. Members of the board took exception to the motion on the ground that the public vaccinator would have no power to carry out the wishes of the guardians without the consent of parents.. Moreover, the question of entry upon school premises would be not unlikely to arise. It is a great pity that vaccination should have been so long neglected in the union, for it is said that there are now 3000 unvaccinated children in Maidstone alone. Examination of children under these circumstances and in face of these facts will avail little unless the guardians supplement their present motion by a determined attitude towards defaulters. The small-pox data coming from Gloucester show that the cases are falling off again in amount in that city. Last week the new cases recorded were only 25, as compared with numbers for the preceding four weeks reaching 84, 47, 42, and 56. Up to Thursday, June 11th, the total of small-pox cases during the present epidemic was 1936. In the week ended last Saturday the registered deaths from the disease of persons belonging to Gloucester were 8 in number, as compared with 17 in each of the two preceding weeks. In the seven days ended the 11th inst., the discharges from the small-pox hospitals were 38, and the admissions 10 in the same period. All round, therefore, the city is in brighter case than for a long time past. Much interest was manifested locally last week by reason of the proceedings against Mr. E. H. Spring, pastor of the East End Tabernacle, in respect of his having wilfully exposed himself in a public vehicle whilst in an infectious condition consequent upon a mild attack of small-pox. The decision of the Bench was against the pastor, who was fined £5 and costs, a second charge of wilful exposure of himself whilst suffering from small-pox being withdrawn on payment of costs. The evidence forthcoming as to the period of infectivity of small-pox attacks was very diverse, but strongly against the defence set up that the defendant was in a condition to mix with others without danger of spread of infection. More proceedings were last week taken against defaulters under the Vaccination Acts at Gloucester, and a case was also before the court in which a man had failed to notify cases of small-pox in his house. Six cases of small-pox have occurred in one household at Kerne Bridge, near Ross, comprising a man, his wife, three children, and a male lodger. The cases are supposed to have been imported from Gloucester. There is no isolation hospital accommodation and a special nurse has been engaged to look after the patients, the house being isolated and every precaution taken to prevent the spread of the disease. A fresh case of small-pox has quite recently developed at Bridgend, just as the medical officer of health had hoped to be able to certify that the town was free from the disease.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Factory and Workshop Legislation.

THE Home Secretary has had prepared a Bill consolidating the various Factory and Workshop Acts which at present give rise to so much perplexity and uncertainty, and his hope is to be able to introduce it early next session.

Lamp Accidents.

The Select Committee of the House of Commons on petroleum and petroleum lamp accidents is still pursuing its inquiry. It has been at work during two sessions of Parliament, and so great is the pressure of evidence that it is doubtful whether the inquiry can be completed and the report of the Committee prepared before the end of the present session. Most interesting evidence was given at a recent sitting by Professor Mendeleeff of the University of St. Petersburg, who, of course, is a recognised authority on all matters relating to petroleum. He attributed the danger of fire and explosion to the presence of too much benzine in the oil, and said that by the separation of it a mineral oil could be produced which would be no more dangerous than vegetable oil, the benzine separated being sufficiently valuable to cover the cost of the process. In Russia, he explained, the Government are most anxious to raise the flashing point, and with that view a heavier excise duty is put upon low than upon high flash oil. Not only so, but the Government have offered a premium for a lamp which will burn satisfactorily with oil of a high flashing point and have succeeded in getting one which so burns with oil of a flashing point of 200° F. Professor Mendeleeff admitted that high flash oil in ordinary lamps smokes badly, throws off an evil smell, and does not give a good light: but at the same time he expressed the opinion that the statutory flashing point, which in this country is 73° F., should be raised to at least 100°.

Food Products Adulteration.

The Select Committee of the House of Commons on this subject has arranged to meet next week to begin the consideration of a report which has been drafted by the Chairman, Mr. T. W. Russell.

HOUSE OF COMMONS.

THURSDAY, JUNE 11TH.

Treatment of Imbeciles in Ireland.

Mr. Engledew asked the Chief Secretary to the Lord Lieutenant of Ireland whether the Government had decided what steps they intend taking with regard to the recommendation made by the Inspectors of Lunatics and Commissioners of Control in the report dated Lunacy Offices, Dublin Castle, Jan. 8th, 1896, as to the great want existing in Ireland of a national institution for the training and education of idiots and imbecile children, in order that these classes might be removed from what the report of the Commission describes as the neglect and poverty of their own homes and from the contaminating influence of association with the adult inmates of asylums and workhouses.—Mr. Gerald Balfour replied that he was aware of the views expressed by the inspectors of lunatic asylums on the subject of providing State aid towards the establishment of an institution for the training and education of idiots and imbeciles in Ireland. The matter was one which had his sympathetic consideration, and he hoped to be able at some time to introduce legislation dealing with it.

The Dangers of Factory Labour.

Mr. Schwann asked the Secretary of State for the Home Department whether his attention had been called to the statements of various inspectors (in the recent report of Her Majesty's Chief Inspector of Factories and Workshops) that proper precautions were still not taken in indiarubber works to protect the workers, often women and girls, from the pernicious effects of sulphurous fumes, which cause various illnesses, nausea, and even paralysis; and also to the statement in the same report as to the absence in some manufactories of hats, of suitable fans, and other means of ventilation, to prevent the entry into the lungs of the workers of particles of fur and dust given off in the fur-blowing processes; and whether he had power, and would exercise it with renewed energy, to cause the proprietors in both industries to take every precaution to obviate the highly deleterious effects of these operations.—Sir Matthew White Ridley said he had seen the statements of Her Majesty's inspectors. Both points were now under the consideration of the Committees on Dangerous Trades, and when he received their reports he would consider what further precautions might be necessary.

FRIDAY, JUNE 12TH.

Salvation Army Shelters.

Dr. M'Donnell asked the President of the Local Government Board whether his attention had been drawn to the reports of Dr. F. J. Waldo, medical officer of health to St. George-the-Martyr, Southwark, which stated, besides other matters, that on the occasion of a night visit to the Blackfriars Salvation Army Shelter, the air therein was not only dangerous to health but also to life itself; and whether the Government would make provision so that Salvation Army and other night refuges of a similar nature be placed within the purview of the Common Lodging Houses Act.—Mr. Chaplin replied that he was aware of the report of Dr. Waldo with reference to the Blackfriars Salvation Army shelter. On the night in question, when Dr. Waldo reported that the shelter was overcrowded so as to be dangerous to health and to life itself, there were 1031 inmates of the shelter. Proceedings in consequence were taken by the vestry of the parish and an order of prohibition of the overcrowding was made by the magistrate, who considered that 550 should be regarded as the limit of accommodation. Subsequently, an application was made to the High Court, with a view to the order of prohibition being quashed. A rule *nisi* for a *certiorari* was granted, but after argument the rule was discharged. The decision

Digitized by Google

of the High Court showed that the shelters were subject to the provisions of the Public Health (London) Act as regards overcrowding, and that those provisions could be enforced in the case of a shelter in like manner as in the case of overcrowding in a dwelling-house. The existing law was, therefore, adequate to meet the case of overcrowding in these shelters, and it was not necessary for this purpose that it should be provided by legislation that the shelters should be common lodging houses.

MONDAY, JUNE 15TH.

Village Water-supply.

Mr. Jeffreys asked the President of the Local Government Board whether the parish council of any parish had power to clean out or enlarge the public pond in the village in order to obtain a better supply of water for the parish, and whether the parish rates could be applied for this purpose; and if the parish council had not the power to do this what authority had that power.—Mr. Chaplin replied that a parish council had power to utilise any well, spring, or stream within the parish and to provide facilities for obtaining water therefrom if they did not interfere with the rights of any corporation or person, but whether this power would enable them to execute works of the kind referred to in the question must depend on the circumstances of the particular case. A rural district council had full power to do any necessary acts to provide a supply of water proper and sufficient for public and private purposes, and in order to obtain a better supply of water for a parish in their district they might clean out and enlarge a public pond if they did not interfere with the rights of others.

Sanitary Accommodation in Mills.

Mr. Schwann asked the Secretary of State for the Home Department (1) whether his attention had been drawn to the statement by the women inspectors (in the recent report of Her Majesty's Chief Inspector of Factories and Workshops) that they criticise most unfavourably the sanitary accommodation provided in Lancashire and Yorkshire in many mills, and complain that the inspectors had no power to enforce a standard of decency as well as of cleanliness, sanitary arrangements being often without regard to privacy or propriety; (2) whether he was aware that England was the only great industrial country in Europe which had no clause in its factory legislation requiring general propriety as well as health in these arrangements; and (3) if he would undertake that in any future factory legislation to be undertaken by the present Government special regard would be paid to this point.—Sir Matthew White Ridley replied: I have seen the statements referred to in the question; but at the same time the inspectors state that in many cases, on the defects being pointed out, improvements have been effected. With regard to the second and third paragraphs of the question, the hon. member appears to have overlooked the provision made by Section 35 of the Act of last year that factories and workshops shall be provided with suitable as well as sufficient accommodation. It is too soon at present to judge of the effect of that section, which only came into force at the beginning of this year, but it appears to me to be adequate for the purpose, and in view of it I cannot agree that England is behind other countries in its legislation in these matters.

The Grant for Lunatics.

Mr. Chaplin, in reply to Mr. Ashton, said he had received a large number of communications on the subject of extending to workhouses the 4*s.* grant per week for lunatics now given to lunatic asylums and had given careful consideration to the matter. Nothing, however, could be done without an alteration in the law, and at present he was not prepared to propose legislation with regard to it.

TUESDAY, JUNE 16TH.

The Army Medical Department.

Dr. Farquharson asked the Under Secretary of State for War whether having regard to the paucity of candidates at the last examinations for commissions in the Army Medical Department, it was proposed to issue a new warrant remedying the grievances of the officers of that Department and, if so, whether the promulgation of such new warrant might be expected before the next examination in August.—Mr. Powell Williams replied on behalf of the Under Secretary, saying that the Secretary of State had the whole question of the paucity of candidates for the medical staff under his consideration. Whether it would result in the issue of a new warrant and, if so, when that warrant would be issued he could not at present say, but the matter would not be lost sight of.

BOOKS, ETC., RECEIVED.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—Resident Medical Assistant for six months. Board, lodging, and washing provided.

Births, Marriages, and Deaths.

BIRTHS.

BELL.—On June 13th, at Upgate, Louth, Lincolnshire, the wife of Charles W. J. Bell, M.R.C.S. Eng., of a daughter.
KEYWORTH.—On June 6th, at Wem, Shropshire, the wife of George Hawson Keyworth, M.B., of a son.
POWELL.—On June 12th, at Upper Clapton, N.E., the wife of Herbert E. Powell, M.R.C.S., L.S.A., of a son.
PRATT.—On June 11th, at Rugby, the wife of W. Sutton Pratt, M.D., L.R.C.P. Lond., of a daughter.
ROSE.—On June 11th, at Harvey-road, Leytonstone, Essex, the wife of Percy Rose, L.R.C.P. Lond., of a daughter.
RICHARDS.—On June 13th, at 47, Churnet-street, Manchester, the wife of Arthur Izod Richards, M.R.C.S., L.S.A., of a son.

MARRIAGES.

AINSWORTH—BRYDEN.—At St. Paul's Church, Shipley, on June 11th, by the Rev. A. Cribb, Vicar of Shipley, assisted by the Rev. C. Strong, Vicar of Windhill, W. T. Ainsworth, M.B., C.M., Marjoribanks, Windhill, to Jessie, second daughter of the late Robert Bryden, Esq., of Cross Banks, Shipley.
BATESON—DURHAM.—On June 16th, at St. Paul's Church, South Hampstead, by the Rev. T. Field, assisted by the Rev. J. W. Bennett, William Bateson, Fellow of St. John's College, Cambridge, son of the late Rev. W. H. Bateson, D.D., Master of St. John's College, to Caroline Beatrice Durham, daughter of the late Arthur Edward Durham, F.R.C.S., Consulting Surgeon to Guy's Hospital, Member of the Council and Past Vice-President of the Royal College of Surgeons, England.
BROCK—BUTLER.—On June 11th, at St. George's, Wrotham, Kent, by the Rev. Canon Erskine Knollys, George Sandison Brock, M.D., C.M., F.R.S.E., of Rome, to Lily Maria, youngest child of J. Hampden Butler, of Ashford, Middlesex. (South African papers please copy.)
BRAUND—SHEARME.—On June 10th, at St. Matthias's Church, Plymouth, Arthur Robert Mather Braund, M.R.C.S., L.R.C.P. Lond., of Hill-side, Stratton, to Margaret Jane Shearme, daughter of the late Edward Shearme, of Stowe, Kilkhampton.
BUCHANAN—ATKINSON.—On June 15th, at the British Consulate, Lausanne, and at Christ Church, George Seaton Buchanan, M.D., of London, son of the late Sir George Buchanan, M.D., F.R.S., to Rhoda Atkinson, daughter of the late Thomas Atkinson, of Windermere.
GIVEN—GARNETT.—On June 10th, at St. Ann's Church, Turton, Lancashire, John Cecil Mackmurdo Given, M.D. Lond., of Mossley-hill, Liverpool, to May, eldest daughter of J. Garnett, of Bromley-cross, near Bolton.
HOARE—GOWLAND.—On June 10th, at Holy Trinity Church, Eastbourne, by the Rev. W. A. Bathurst, Edwin Stanley Hoare, M.R.C.S., L.R.C.P., son of the late Joseph J. Hoare, and grandson of the late S. P. Low, J.P., of Round Hill Villa, Sydenham, to Jessie May, only daughter of Thomas Stafford Gowland, of Eastbourne.

DEATHS.

ARMITAGE.—On June 4th, at Greenhithe, Kent, Alice, the dearly-loved wife of S. H. Tatham Armitage, M.D., 39, Grosvenor-street, W., aged 63 years. Funeral took place at Scarborough, June 8th. Friends will please accept this intimation.
AYRE.—On June 9th, at Cheltenham, William Gordon James Ayre, Fleet Surgeon R.N., in the 70th year of his age.
KIRBY.—On June 15th, at Cambridge-terrace, Hyde-park, Thomas Charles Kirby, M.D., in the 63rd year of his age.
PAGET-BLAKE.—On June 12th, at Alverstoke Vale, St. Marychurch, Torquay, Charles Paget-Blake, M.D., F.R.C.P., Retired Surgeon R.N., aged 76.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.).

TUESDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (24th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY (25th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Great Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.) Gt. Northern Central (2.30 P.M.).

SATURDAY (27th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (22nd).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Mr. W. R. H. Stewart: Some complications of Middle Ear Suppuration.

TUESDAY (23rd).—HOME FOR TREATMENT OF WOUNDS AND ULCERS BY OXYGEN (35, St. George's-sq.).—4 to 5.30 P.M. Demonstrations of Treatment, Apparatus, and Cases.

WEDNESDAY (24th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Gowers.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Payne: Selected Cases.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. W. Hunter: Pathological Demonstrations.

THURSDAY (25th).—LONDON POST-GRADUATE COURSE.—Brit. Inst. of Preventive Medicine, Gt. Russell-st., W.C., 3.30 P.M., Dr. Allan Macfadyen and Mr. A. G. Foulerton: Detection of Drugs in Urine.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. J. Hopkins: Clinical Lecture.

VICTORIA HOSPITAL FOR CHILDREN (Tite-street, S.W.).—4 P.M. Mr. Waterhouse: Adenoid Vegetations in the Naso-Pharynx and their Treatment.

HOME FOR TREATMENT OF WOUNDS AND ULCERS BY OXYGEN (35, St. George's-sq.).—4 to 5.30 P.M. Demonstrations of Treatment, Apparatus, and Cases.

FRIDAY (26th).—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Tetanus, Rabies, and Cholera.

SATURDAY (27th).—HOME FOR TREATMENT OF WOUNDS AND ULCERS BY OXYGEN (35, St. George's-sq.).—4 to 5.30 P.M. Demonstrations of Treatment, Apparatus, and Cases.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

THE HEAT.

To the Editors of THE LANCET.

SIRS,—To the medical man next in importance to the study of his patient's constitution is the study of what Sydenham called the "constitution of the season." Without any pretensions to extra foresight we may assume that we have got to deal with a hot season. For some weeks past—though we are now only in the middle of June—we have had summer weather with scarcely any rain till the beneficent fall of last week. One morning this week at 8 o'clock the outside thermometer in the shady side of the house was 70° F., and the underground thermometer, four feet deep, recorded a heat of over 55°—a temperature which, as Dr. Ballard tells us, has warnings for those concerned with the public health. It becomes a public question how to reduce the risks of such an extreme of temperature, to which, coming so seldom in our somewhat dull climate, we are apt to be inattentive. Apart from risks of sunstroke, with its head congestion and high temperature, dyspnœa, and heart failure, we may expect to see various degrees of "heat-exhaustion," characterised by great prostration and low temperature, and liability to summer catarrhs. Epidemic diarrhœa is not seen now on such a scale as was common before the sanitary era initiated by Chadwick, Simon, and others, and which made summer a busy season for medical men. But it is still serious enough to figure largely in the public bills of mortality of the season. It has never yet been shown exactly how much of the influence of the sun, as we have it, is due to its direct effect on the human body, and how much to its effect on food, drink, &c. To be forewarned is to be forearmed. Insolation with us is a much more preventable accident than in most countries. We have only to practise a few of the most obvious precautions to escape its risk in any serious form. One of these is to do most of our work in the cooler periods of the day, early and late, while the sun is not putting forth all his power. Another point is to make much of the night by cooling down bedrooms, and by a window open a little top and bottom to secure fresh air to favour sleep. The regulation of food is another chief security. Animal food cannot be dispensed with, but it should be in light forms and moderate quantities, often cold with salad, instead of hot with questionable new potatoes. Above all things in hot seasons care is necessary in the use of alcohol. Beer and spirits are recognised as dangerous in hot countries. Light wine well diluted and, at the proper time, tea, or coffee, are sustaining.

I am, Sirs, yours truly,

June 15th, 1896. M.D.

Mr. Richmond Leigh.—We agree with our correspondent to a certain extent, but he must remember that the addresses were delivered not to specially scientific audiences, but to the members of the medical corporations.

Vaccination must send us full particulars before we can answer his question. Where were the diplomas obtained and when?

"AN INSURANCE OFFICE AND A MEDICAL REFEREE."

To the Editors of THE LANCET.

SIRS,—In the issue of THE LANCET of May 2nd you kindly inserted under this heading a summary of some correspondence between the manager of the Sickness and Accident Association of Edinburgh and myself, and this summary was absolutely correct, but the manager directly contradicts my statement that they offered me 5*s.* for the examination. My only desire in forwarding the correspondence was to point out the unsatisfactory basis of insurance fees, with the hope that some more reasonable basis might ultimately be suggested, but I did not wish to introduce in any way personal considerations, and therefore asked him to correct the mis-statement which he had made, but apparently he prefers that I should be regarded as a perverter of the truth. I now enclose letters from him and from his agent acknowledging that the offer of 5*s.* was made, although they now say that it was made "in error," and that the magnificent sum of 7*s.* 6*d.* should have been stated instead. I do not wish to comment upon this behaviour, but I trust that you will insert this letter in fairness to me and also in order that your readers may form their own estimate of the office. I have withdrawn my own policy.

I am, Sirs, yours truly,

Great Berkhamsted, June 8th. SIDNEY A. BONTOR.

*** Dr. Bontor encloses two letters, one from the manager of the Sickness and Accident Assurance Association, Limited, and the other from Mr. P. F. Maples, St. John's Vicarage, Mansfield, an agent for the same Association. The manager states that the offer of 5*s.* was not made by the authority of the Association, though he adds "that it was made I do not for a moment dispute." The agent says that he made a mistake in offering 5*s.*, and he appears to think that Dr. Bontor ought to have detected that he was new at his work. It is quite clear that Dr. Bontor's statement, upon which we founded our remarks on May 2nd, 1896, was entirely exact, and that the manager's contradiction, which we inserted on May 16th, was incorrect. The offer which the manager says was not made was made, and by an agent of the association.—ED. L.

T. L. H.—Our correspondent does not specify for what object he wishes to consult the works about which he enquires. The best book of reference is not necessarily the best manual for an examination. Fagge's, Bristowe's, Osler's, Taylor's, and Roberts's treatises on Medicine, Erichsen's, Holmes's, and Treves's on Surgery, are household words, and Quain's Dictionary of Medicine must not be omitted; the first volume of Dr. Clifford Allbutt's System of Medicine is now out, while many of the articles in Reynolds's System are as well worth reading now as they were when they were written.

"IODISM."

To the Editors of THE LANCET.

SIRS,—I have read your correspondent Dr. A. Veitch's letter *re* Iodism, and the results of his use of the iodide with morphia and also atropia are certainly satisfactory. I should like to know if he has ever tried or knows anything of the strontium iodidi, which I venture to think he will find most satisfactory in all cases. I shall be glad to hear, if your correspondent should give this drug a trial, what results he has experienced. It is to be had in the very convenient form of tablets, which quickly disintegrate. The bromide strontium also is most valuable.

I am, Sirs, yours faithfully,

Harlesden, June 13th, 1896. R. FOSTER OWEN, M.R.C.P. Irel.

Ethics.—Our correspondent informs us that he knows of a case where a gentleman who had been debt collector to a medical man became a qualified medical practitioner, and returning to the neighbourhood proceeded to tout among his old master's clients, trading on his knowledge of their circumstances. It should be added that his master had been succeeded in practice by another medical gentleman, who, we are informed, is suffering from this touting, "several well authenticated cases" having occurred where the patients were invited to give the late collector a trial. We are asked to express an opinion, and can only say that if "Ethics" is correct in his facts the medical man whose patients are invited to try some one else has a right to feel aggrieved.

Dr. H. Mallins.—Apply to the Secretary, Swedish Turist Forening, Stockholm.

Squirt has not given his name and address.

THE PROFESSOR OF BOTANY AT CAMBRIDGE.

To the Editors of THE LANCET.

SIRS,—In your notice of the current number of *Science Progress* which appears in THE LANCET of June 13th, you observe that "on the title page ..... the name of the late Dr. Marshall Ward still appears." Of course this was written under a misapprehension of the fact that Dr. Ward is still Professor of Botany at Cambridge.

I am, Sirs, yours faithfully,

June 16th, 1896. J. BRETLAND FARMER.

*** We apologise to Professor Marshall Ward for the blunder.—ED. L.

PROFUSE ANTE-PARTUM HÆMORRHAGE CAUSED BY WOUND OF THE VAGINA.

To the Editors of THE LANCET.

SIRS,—A short time ago I was summoned to a case at some distance, the message not stating its nature, so that I went unprepared for midwifery. On arriving I found that it was a confinement and the woman had been in labour over twenty-four hours. She had lost a large quantity of blood and I found her approaching a state of collapse, the bleeding having commenced two hours previously to my arrival. On examination I found the cervix well dilated, the head presenting, and the membranes intact. No laceration could be detected in the cervix and no sign of a ruptured varicose vein at the vulva. The blood appeared to come from an artery in the anterior wall of the vagina, and I was puzzled to account for it. An antiseptic plug of lint was passed into the vagina and held against the anterior vaginal wall; this effectively controlled the hæmorrhage. Shortly after this I ruptured the membranes with my finger and the child was born in a few minutes. The placenta was expressed and the uterus contracted well. The hæmorrhage ceased after delivery. A neighbour who was acting as midwife was attending her, and there was also a second woman present, who took me aside afterwards and told me the cause of hæmorrhage was due to the woman acting as midwife, who, wishing to bring the labour on quicker, had taken a pair of sharp-pointed scissors with the intention of "clipping the waters," as she expressed it. Instead of doing this she wounded the anterior wall of the vagina, with the result that hæmorrhage came on immediately. The woman afterwards admitted that she had done it in previous cases. The patient was in a very feeble state for the subsequent three days, her temperature on the second and third day being 100° F. and 101° respectively, and I began to fear some septic absorption had taken place, but her condition improved in a few days and she did well. The vagina was syringed out every day with a warm solution of permanganate of potash. The woman in attendance received such a fright that I do not think she will repeat the proceeding. My excuse for publishing this case is to put on record the disastrous consequences which might ensue from an ignorant person tampering with a labour case. I am, Sirs, yours truly,

E. G. RENNY, M.R.C.S. Eng., L.R.C.P. Lond.

Colchester, June 15th, 1896.

Volunteer.—A surgeon-lieutenant must first ascertain that a commanding officer of a regiment or bearer company of the Volunteer Medical Staff Corps is willing to accept his services. He will then receive from the adjutant a printed form to fill in, consisting of a series of questions, with certificates of moral character, &c. This form, signed by the applicant, is sent through the adjutant to the officer commanding the regiment or bearer company, and by him transmitted, with a letter of approval, to the War Office. The appointment will be gazetted in about a fortnight. He must hold a double qualification. There is no age limit except the age at which he must retire—viz., sixty years, or by special permit it may be extended. When gazetted he can obtain £10 towards the cost of his uniform, and after passing the "P" or "P.S." examination a second £10, so that he receives £20 in all; but if he withdraws before three years he will have to refund the sum to the Government.

Mr. D. Ainsley.—Our correspondent is thanked for his letter, the subject of which we will notice if possible shortly. It is one which might well be brought forward at a medical congress.

A. R.—Our correspondent does not seem to have registered his qualification. The editors of the "Medical Directory" are exercising a proper discretion in deciding that he is not a British practitioner residing abroad, but a German with a British qualification.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Eastern Morning News, Manchester Courier, Scotsman, Civil Service Gazette, Leicester Post, Dundee Advertiser, Hampshire Independent, Cheltenham Mail, Stratford Advertiser, Glasgow Herald, Huddersfield Examiner, Retford News, Bridgwater Independent, South Wales Post, South London Mail, National Observer, Newcastle Journal, Accrington Observer, Western Daily Mercury, Birmingham Gazette, Sussex Daily News, Worcestershire Chronicle, Oban Times, Liverpool Daily Post, Times of India, Blackburn Times, Pioneer Mail, Doncaster Chronicle, Brighton Argus, Builder, Bristol Times, Liverpool Courier, Oldham Standard, Yorkshire Post, Halifax Guardian, Leeds Mercury, Burnley Express, Bolton Journal, Architect, Bristol Mercury, Westminster Gazette, Sanitary Record, Brighton Gazette, Le Temps (Paris), Weekly Free Press and Aberdeen Journal, Lincoln Mercury, Mining Journal, Reading Mercury, Hemel Hempstead Gazette, City Press, Hertfordshire Mercury, Le Courrier de la Presse, Local Government Journal, Surrey Advertiser, West Ham Guardian, Keble's Margate and Ramsgate Gazette, Citizen, North Queensland Herald, Colchester Mercury, Shrewsbury Chronicle, Bury Guardian, Blackpool Gazette, Wigan Examiner, Hereford Times, Derry Journal, Poole Herald, Middlesex and Surrey Express, Torquay Directory, &c., &c.*

Terms for Position Pages and Serial Insertions on application.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière Asnières, Paris.

The Cavendish Lecture

ON

THE CENTENARY OF THE DISCOVERY OF VACCINATION BY EDWARD JENNER.

Delivered before the West London Medico-Chirurgical Society on June 17th, 1896,

BY THOMAS BRYANT, M.CH, F.R.C.S ENG. & IREL.

CONSULTING SURGEON TO GUY'S HOSPITAL; PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, ETC.

MR. PRESIDENT AND GENTLEMEN,—One hundred years ago a medical practitioner residing in a remote village in Gloucestershire, and who might have been described as obscure, wrote to Mr. E. Gardner of Frampton, an old and intimate friend, the following letter, dated from Berkeley, July 19th, 1796.

"DEAR GARDNER,—As I promised to let you know how I proceeded in my inquiry into the nature of that singular disease the cow-pox, and being fully satisfied how much you feel interested in its success, you will be gratified in hearing that I have at length accomplished what I have been so long waiting for—the passing of the vaccine virus from one human being to another by the ordinary mode of inoculation. A boy of the name of Phipps (aged eight) was inoculated on May 14th) in the arm from a pustule on the hand of a young woman who was infected by her master's cows. Having never seen the disease but in its casual way before, that is, when communicated from the cow to the hand of the milker, I was astonished at the close resemblance of the pustules in some of their stages to the variolous pustules. But now listen to the most delightful part of my story: The boy has since been inoculated for the small-pox (July 1st) which, as I ventured to predict, produced no effect. I shall now pursue my experiments with redoubled ardour.

"Believe me, yours very sincerely,

"EDWARD JENNER."

The letter I have just read[1] is now in the possession of the Royal College of Surgeons of England with a large number of other valuable Hunterian, Jennerian, and Baillie records, which are to be treasured by the College for all time as a distinct collection under the name of the Hunter-Baillie collection, the whole having recently been kindly presented to the College through me, according to the wish of the late Mr. William Hunter Baillie and his surviving sister Miss Helen Baillie. The pleasure with which Jenner indited this letter to his trusted friend, and reported the complete success of his crucial with his control experiment on vaccination, can be understood in a measure by all of us, and we can likewise appreciate how by his success in his well-thought-out experiment he was encouraged to go about his work with redoubled ardour. At any rate, the interest the perusal of this letter has raised in my mind and the possession of the letter with other original papers connected with Jenner and his work have induced me in giving this lecture, which bears the honoured name of Cavendish, the great chemist of the air, to bring before your notice the doings of another great Englishman, who has both directly, by the discovery of vaccination, and indirectly, by introducing a new method of investigation, been of incalculable advantage to his fellow creatures all over the world. And as this year is the centenary of Jenner's discovery I have been encouraged to bring his name and good work before you.

Edward Jenner was born at Berkeley, Gloucestershire, on May 17th, 1749, and died on Jan. 26th, 1823. He studied medicine and resided for two years as a house pupil with John Hunter when he was twenty-one and Hunter was forty-two years of age, and always subsequently referred to Hunter as the "dear man." A close friendship between these men succeeded this period for at least a quarter of a century, as proved by a correspondence which continued nearly up to Hunter's death. Indeed, Hunter's opinion of young Jenner must have been very high, for in 1775 when Hunter started his school of anatomy he asked Jenner to join him as a partner; and that the two men were intimate is proved by a letter from Jenner to Dr. Heberden that in 1778 Jenner had recognised the existence of the heart trouble from which Hunter died on Oct. 16th, 1793. In 1771, as soon as Jenner left Hunter's house, he commenced his systematic inquiries into the subject of cow-pox, and particularly into the truth of the floating opinions and scattered observations which had been made as to its influence; for in some of the dairy counties—particularly those of Gloucester and Buckingham—the fact had long been recognised that the dairymaids who had contracted cow-pox were far less susceptible to small-pox than others who were differently placed, and it is more than probable that Jenner had told this to John Hunter and had been stimulated by his precept and example to follow out this clue to its legitimate conclusions. Jenner was probably unaware of an isolated example of vaccination by B. Jesty in 1774, and of another in Holstein in 1791 by P. Plett. At any rate John Hunter never took the subject up, and it was left to Edward Jenner to realise the full value of these observations, to confirm them by way of experiment, and to apply them by a happy thought or stroke of genius to the lasting benefit of his fellow creatures. That Jenner understood the full meaning of the investigation he was following out, and the measure of good his work was likely to achieve if brought to a successful issue, is perfectly clear from the following conversation he had with his friend Gardner sixteen years before he made the crucial experiment recorded in the letter with the reading of which I commenced this lecture, and nine years after he had commenced his study of the subject. In 1780 Jenner, when riding on the road between Gloucester and Newport with his intimate friend Edward Gardner, went over the natural history of cow-pox. He stated his opinion as to the origin of this affection from the heel of the horse—an opinion which was never accepted in Jenner's time, but which has since been established, beyond room for doubt, by H. Bouley of Alfort, he having proved in 1862 the fact that the grease is a specific disease of the horse analogous to cow-pox and interchangeable with it. He likewise specified the different sorts of disease which attacked the milkers when they handled infected cows; dwelt upon that variety which afforded protection from small-pox; and with deep and anxious emotion mentioned his hope of being able to propagate that variety from one human being to another till he had disseminated the practice all over the globe, to the total extinction of small-pox. "Gardner," he said in conclusion and with great emotion, "I have intrusted a most important matter to you, which I firmly believe will prove of essential benefit to the human race. I should not wish what I have stated to be brought into conversation, for should anything untoward turn up in my experiments I should be made by my medical brethren the subject of ridicule." In 1780 the conversation I have just quoted took place; in 1796, sixteen years later, the success of his crucial experiment was reported to the same friend; and between 1796 and 1798, when he published his first treatise on cow-pox, he repeated the experiment over and over again. Indeed, he inoculated at least 100 children with cow-pox, and subsequently at different intervals with small-pox without effect before he ventured to communicate his discovery to the world. Jenner did not publish his discovery till 1798—that is, two years after the success of the crucial experiment he had performed on the boy "Phipps," which had proved to him the truth of his theory, and which helped him, as he expressed it, to pursue his experiments with redoubled ardour. He was not so eager to reap the fruit of his labour as to bring it to market before it was ripe, but he cautiously went over the ground again and again, by experiment and counter-experiment, until there was no room for doubt; so that when, in June, 1798, he gave the ripe conclusions of his prolonged investigation under the heading of an "Enquiry into the causes and effects of the variolæ vaccinæ" to an astonished and admiring world, its form and substance were so clear, simple, and convincing that his work was at once accepted and the practice based upon it speedily diffused over all countries. Indeed, France, Russia, Germany, Austria, Spain, Switzerland, Denmark, Norway, America, and India all vied with one another in their efforts to spread the means of contending with such a loathsome and fatal malady as small-pox had for so many centuries proved to be.

France forgot its jealousy and accepted the boon from England's son with candour and alacrity. She founded

institutions and societies for its extension under Government sanction, and the central government committee reported so early as 1802 that "there has not been one example to prove that amongst ten thousand individuals inoculated with the cow-pox a single one has been infected with the small-pox, though being in the midst of the contagion." In 1803 they were still convinced of the reality of the advantages ascribed to it, and returned what they described "as a just tribute of acknowledgment to Dr. Jenner, being fully persuaded that he will hereafter be remembered among those who have reflected the greatest honour on science and rendered the most important service to mankind." Dr. Valentine of Paris worked nobly to introduce and extend the practice.

In 1803 the Government of Denmark so effectually enforced the practice of vaccination that small-pox was rapidly extirpated from the country, and soon afterwards it prohibited variolous inoculation altogether. In 1821 not a single case of small-pox had occurred in Denmark for a period of eleven years. In 1826, however, a traveller from Hamburg re-introduced the disease.

In Sweden vaccination was taken up very warmly, and as a consequence in 1802 variolous inoculation had been given up and in 1803 vaccination was established by law. On Feb. 10th, 1814, the Government of Sweden reported that small-pox had been perfectly extirpated in that country. In 1823 its mortality, at any rate, had dropped from 15,000 a year to 37. Dr. Edwardes has within the last month recorded the facts, as demonstrated by official records, that whereas before vaccination 1 death occurred every year from variola in every 488 of the population, the average annual mortality of the disease for the last seventy-seven years has been 1 in every 6451, or $\frac{1}{13}$th part of the former average.

In 1801 vaccination was introduced into Russia, and the story of its introduction, which is so indicative of faith in its value and energy in its use, is worthy of repetition. The Court was at Moscow on account of the coronation of the Emperor, and the child who was first inoculated was patronised by that exalted and truly philanthropic personage, the Empress Dowager, who named her "Vaccinoff," sent her in one of her own coaches to St. Petersburg to be placed in the Foundling Hospital, and settled on her a pension for life. Her Majesty likewise transmitted on Aug. 10th, 1802, a valuable diamond ring to Dr. Jenner accompanied by a flattering letter written by her own hand. This act was followed by the adoption of vaccination throughout the Russian dominions. The nobles themselves inoculated the peasants with their own hands. Indeed, in Russia vaccination proved so successful that it was termed in the language of the country the "pock of surety," and no wonder, when we were told that variola before that period was the cause of death in Russia of every seventh child and sometimes was said to have destroyed two millions of people in a year. Woodville and Guthrie, two great authorities of that day, believed it not improbable that the great population of these regions, which formerly enabled them to pour such immense numbers over Europe, had been greatly lessened by this disorder.

In Germany vaccination was introduced through Hanover, and the King of Prussia was the first crowned head who had the vaccine inoculation performed on his own children. He established a vaccine institution in the capital of each part of his dominions and appointed a Berlin physician to the institution in that city with a suitable salary.

In Austria vaccination was introduced into Vienna in 1801 and taken up very warmly by Dr. de Carro of that town, who, when he vaccinated a child of a medical friend four and a half hours after its birth, expressed the wish that vaccination and christening should be one ceremony as by such a practice small-pox would be soon eradicated. It was said that this excellent idea was supported by the celebrated Dr. Darwin, who, from opposing the practice at its commencement, became before the year 1802 one of its warmest supporters.

Its effects in diminishing the mortality of small-pox in Vienna was very evident by comparing the number of deaths since its introduction in 1801 down to 1804 with the average of the ten years before its introduction:—From 1791 to 1800 inclusive the deaths were 835 a year; in 1801 (the year of the introduction of cow-pox into Vienna) the deaths were 164; in 1802, they were 61; in 1803, 27; and in 1804, 2.

In Lombardy the practice was so popular and so much enthusiasm as to its adoption was felt that in 1805 Dr. de Carro of Vienna reported that Dr. Sacco travelled from one town or village to another and the children were assembled in order to be vaccinated by the ringing of the church bell.

Spain took up the practice of vaccination very warmly, and both at home and abroad spared no efforts to confer its benefits upon all its children—indeed, one of the prettiest incidents connected with the early history of vaccination was brought about by the Spanish Government and is worthy of being recalled to mind. When evidence had been brought before the Spanish Government that both in India, Ceylon, and other Asiatic countries the vaccine inoculation had completely succeeded, "the Spanish monarch resolved to fit out an expedition for the express purpose of carrying to all the possessions of the Crown of Spain beyond the seas and to those of several other nations the inestimable gift of vaccine inoculation. An expedition was prepared which set sail from Corunna on Nov. 30th, 1803, under the direction of Dr. Francis X. Balmis, Surgeon Extraordinary to the King. There were on board twenty-two children who had never undergone small-pox selected for the preservation of the vaccine fluid by transmitting it successfully from one to another during the voyage. After an absence of nearly three years the able conductor of this philanthropic expedition returned to Madrid having circumnavigated the globe and having more than realised the most sanguine expectations that were entertained at his departure."

In America vaccination made early and rapid way, for Dr. Waterhouse as soon as he received a copy of Jenner's book, which he did within six months of its publication, was so struck with the importance of the subject and the incalculable benefit which might accrue to his country from its adoption, that he immediately communicated to the public a sketch of the discovery, and this effort on his part was most favourably received by Mr. John Adams, the then President, who wrote on Sept. 10th, 1800, "to disarm the small-pox of its contagion is an enterprise worthy of a Hercules in medicine." Mr. Jefferson, the succeeding President, continued to support the same, so that in 1802—four years after Jenner's book was published—vaccination had become widely extended through the United States and likewise amongst the Indians, who received it as a blessing from Heaven.

In 1806 it was reported that in Mexico and Peru, where small-pox every year had played sad havoc, by means of vaccination, variola had lost much of its malignity, so that at that date—eight years after its introduction—the number of children who fell victims to it had been reduced in the proportion of nine to one.

In China, even, much success was soon achieved, and at Canton the first British book that had ever issued from a Chinese press was published upon the subject in order to promote the knowledge of the discovery.

In India the practice was rapidly adopted and extensively practised. In 1802 it was recorded that no less than 800,000 natives had been vaccinated. The Brahmins at first objected to it as it proceeded from the sacred cow, but when the chief of the Mahratta empire had one of his own children vaccinated many others followed suit, and so at last the cow-pox inoculation became so popular as to be named "the dew of heaven."

In England, and particularly in London, vaccination, in common with all other great movements, was sadly opposed—prejudice and the pleasure of opposition had its influence, and inefficient and careless methods helped both. A striking instance of incredulity was exhibited on March 28th, 1808, at a place of public discussion in London called the British Forum, when the following subject was brought forward for discussion: "Which has proved a more striking instance of the public credulity, the gaslight of Mr. Winsor or the cow-pox inoculation?" The result of the discussion was that both gaslight and cow-pox were handed over to scorn and ignominy. That incredulity as to the value of vaccination itself was rapidly displayed after its introduction was not surprising, as well as incredulity as to the relative value of cow-pox and small-pox inoculation, which was then in vogue; indeed, such feelings were but natural. Hostility and opposition to the practice of vaccination as well as to the theory upon which it was based were also to be anticipated, for the curious tribe of anti's, including "anti-vaccinists," as they were then called, has always been present in the world and still exists; and although those unreasonable people may do some harm amongst the thoughtless and ill-informed, they help to stimulate healthy exertion and at the same time give the public an opportunity of studying human nature in one of its oddest forms. Nevertheless, it is clear that hostility to the

practice of vaccination was very serious, for the writer of an able article in the *Edinburgh Review* for 1806 upon the subject (vol. iv., p. 33) wrote that "in the whole course of our censorial labours we have never had occasion to contemplate a scene so disgusting and humiliating as is presented by the greater part of this controversy; nor do we believe that the virulence of political animosity amongst the lowest scribblers ever gave rise to so much coarseness, illiberality, and absurdity as is here exhibited by gentlemen of sense and education discussing a point of professional science with a view to the good of mankind." That carelessness in the operation of vaccination and in the transference of the vaccine virus had in Jenner's time, as in our own, some influence for harm in an occasional instance is also true; but such a fact is no more an argument against vaccination than any other act, for carelessness, of all human virtues, must be calculated upon as a human certainty. In Jenner's time carelessness must, however, have had a more pernicious influence, for the vaccine inoculation was not confined to members of the medical profession. In 1800 it was openly practised by some of the clergy. In a pamphlet before me, dated 1806, I read that a Mr. J. T. Read, who was curate of Leckhampstead and Akeley, near Buckingham, in March, 1800, began to vaccinate both the labourers of those villages and vast bodies of men who were working at the Grand Junction Canal, which was then in progress, and that in the course of six years he had inoculated upwards of 4700 persons and that not one of his cases had subsequently had small-pox although many had run extreme risks. This custom of amateur vaccination was, indeed, so general that the National Vaccine Establishment, in its report for 1815, drew attention to it in the following terms, which, please note, are commendatory and not, as they would have been in this age of Medical Acts, the reverse: "The board cannot omit to direct your Lordships' attention to the *meritorious conduct* and zealous exertions of private individuals, not of the medical profession, who have not only vaccinated many hundreds every year, but who have studiously maintained a supply of lymph in their districts for the perpetual renewal of vaccination. It has particularly noticed the ardent zeal of Mr. Ellis of Rhos farm, who has vaccinated several thousands in North Wales without a single failure, and also of the late Rev. Mr. Holt and the Rev. Mr. Finch, two of the earliest friends to the practice and who met with undeviating success, a success which puts to shame the negligent practice of some belonging to the medical profession." In 1818 the National Vaccine Establishments were so pleased with public non-professional assistance that they appointed honorary vaccinators to help in their work, and most of them were private gentlemen, ardent patrons of vaccination. This act on their part was somewhat curious, for at this time the same establishment began to recognise the necessity of acquiring knowledge as to the best modes of practice, for reports came in of failures, or supposed failures, which were of course exaggerated in the eyes of the public and helped the quacks and sceptics to encourage variolous inoculation, which at this period of the world's history seemed to be very much in their hands, with those of farriers, publicans, nurses, and low, cunning people of both sexes and of various descriptions.

I propose now to say a few words about the success of vaccination, for its very success at the present time is employed as an argument against its use. Indeed, small-pox since the introduction of vaccination has so steadily and rapidly diminished that the present generation of people until lately have little knowledge of its existence, and consequently hardly understand the necessity of seeking a preventive for an affection which seems so remote; and I question whether the present generation of medical men are fully alive to its former dangers. The following brief observations may consequently be of interest. It may be accepted as a correct statement that before the vaccine inoculation was introduced in 1798 3000 lives in London and 40,000 in the United Kingdom were *annually* the direct victims of small-pox, and that these numbers multiplied by six—or 18,000 in London and 240,000 in the United Kingdom—indicated the number of people who had been affected with the disease every year. Out of every 1000 persons who died from any cause, 100 died from small-pox and 600 had it; for 1 out of every 6 infected with small-pox died from it. This mortality was calculated when the practice of variolous inoculation had been very general, whereas before inoculation was introduced 1 out of every 3 persons attacked by natural small-pox died. It may also be accepted as true that of those who survived the ravages of the disease a number—at least twice as large as that given to indicate its fatal average—were afflicted with blindness or hideous deformity which rendered life miserable. Indeed, Mr. Moore, the author of an excellent pamphlet (A Reply to the Anti-vaccinators of 1806) referred to the well-known institution in the South of London for instructing the indigent blind, and reported that no less than three-fourths of its occupants had lost their sight from the small-pox. These figures taken together suggest an amount of preventable human misery which is appalling, as it affected every year 130,000 of our own country-men and -women. At the present time the mortality of small-pox appears but trifling, for in 1894 the Registrar-General reports that in a population of over 30 million persons in which the death-rate was 16·6 per 1000, the deaths from small-pox were only 820 or 27 per million people, or one death from small-pox in every 37,000 persons. And in 1895 in the metropolis out of a population of 4,400,000 there were 55 deaths from small-pox, or one in every 80,000; and out of 1546 deaths one only was from variola, whereas 100 years ago, instead of one death from variola out of the 1546 deaths there would have been 154 deaths. In the Continental war of 1870, in the well-vaccinated German troops there were but 300 deaths from small-pox; whereas in the imperfectly-vaccinated French army there were 23,400 deaths from the same disease. Jenner always considered small-pox and cow-pox as modifications of the same distemper, and that in employing vaccine lymph, we only made use of means to impregnate the constitution with the disease in its mildest, instead of propagating it in its virulent and contagious, form, as is done when small-pox is inoculated.

"It is," he wrote later, "the small-pox in a purer form than that which has been current among us for twelve centuries past. The security given to the constitution by vaccine inoculation is exactly equal to that given by the variolous. To expect more from it would be wrong."

In 1811 Jenner wrote: "At the commencement of vaccination, I deemed variolous inoculation after vaccination the necessary test of security. I now—that is, thirteen years later—feel confident that we have one of equal efficacy, and infinitely less hazardous, in the re-insertion of the vaccine lymph." Jenner clearly by this observation recognised the value of re-vaccination. He also advocated the use of lymph from the calf when it can be procured.

The question of variolous inoculation claims briefly our attention, for it was carried out throughout the world for many years with variable success.

The practice of inoculating the small-pox as we now vaccinate for cow-pox was recognised in Constantinople and Venice in 1714–15, and although its introduction into England was said to have been at about that date, its true adoption was unquestionably due to the influence of Lady Mary Wortley Montagu, the wife of the British ambassador at Constantinople in 1717, who had a child of hers so inoculated at Constantinople by Mr. Maitland, surgeon to the embassy of that town, and in 1722 a second who was in England, this case being the first known subject of the new practice in civilised Europe. The practice, however, made but slow progress, and in 1740 it had almost fallen into disuse. But about this date good accounts of its success had been reported from South America and the West Indies, and under this influence the practice was revived.

In 1754 variolous inoculation was described as a noble and blessed discovery, and the College of Physicians declared their fullest approbation of the practice and thus favoured its adoption. They failed, however, to support as they ought to have done the recommendation to keep the infected apart from the non-infected members of the population. As a consequence of this support from high quarters, variolous inoculation became prevalent in 1760. In 1768, or eight years later, what was known as the Suttonian method of inoculation also helped to spread the practice, aided by the encouragement given to it by the Empress Catherine of Russia who invited Dr. (afterwards Baron) Dimsdale of this country over to St. Petersburg to inoculate her and her son Paul. Nevertheless, inoculation of small-pox was but a mixed blessing, for experience proved that instead of mitigating it actually extended the evil, for although the proportion of those who died by it out of a certain number infected (1 in 200) was less than before its adoption, when it was 33 in every 100, yet the actual number carried off by it was greater. The cause of this was obvious: while the small-pox

Digitized by Google

was more fatal in appearance caution was alive, and when ever the disorder appeared it carried such terrors with it that communication was cut off as much as was practicable and every house was shunned as a pest-house where its effects were so visible. A plague that carried off a third of those attacked, it was natural to fly from; but when by the introduction of inoculation and an improved mode of treatment it happened to be fatal in one only in 200 it gradually became disregarded; the horror which before attached to it vanished as the same consequences did not ensue, and the spreading of the infection was no longer considered as so great an evil. Lady Mary Montagu, indeed, in one of her letters remarks: "Every year thousands undergo the operation"; and the French ambassador of the period said, pleasantly, that "they take the small-pox in Paris by way of diversion as they take the waters in other countries." Contagion in consequence spread widely around and the world little regarded what would have appeared to them as a paradox, but which, however, may be easily explained. Dr Letteom, the great physician of the time, explained this to the Committee of the House of Commons, and proved from the yearly bills of mortality that between 1667 and 1722 the average number of deaths occasioned by the small-pox was to the whole number that died as 72 to 1000, whereas in the forty-two years after inoculation was in use—namely, from 1731 to 1772—the proportion of death was no less than 89 to 1000, being an increase of nearly one-fourth, and Dr. (subsequently Sir Gilbert) Blane later showed that in the following thirty years from 1772, before vaccination had had time to tell upon statistics, the mortality had increased to 95 in 1000. Dr. Blane also showed how by the inoculation of small-pox the disease was spread more extensively and became more fatal in the country than in London. For at that time there were certain districts in which small-pox previously to the introduction of inoculation was unknown for twenty, thirty, or forty years, so that great numbers of people had died without ever having had it; but in the latter years of the last century, for the reasons adduced and from the extended communication between the distant parts of the kingdom, an adult who had not had the small-pox was hardly to be found. Although therefore, variolous inoculation may have relieved individuals who availed themselves of its protection, it was a great evil to the people generally by universally spreading the disease. It was, however, productive of some good things, and amongst these stands the foundation of the London Small-pox Hospital, which was founded in 1746 primarily for the purpose of inoculating the poor gratuitously with variolous matter and secondarily with the better object of keeping the patients so inoculated distinct from the general population of the country. At this period this good object could not have been very generally appreciated, since, as I have already pointed out, the Royal College of Physicians, when it declared eight years later, in 1764, its fullest approbation of the practice of variolous inoculation, failed to emphasise the necessity of separating the infected from the uninfected. The Small-pox Hospital, however, continued its good work, and when vaccination was first introduced its officers at once adopted the practice. They did so also with such good effect that in 1803, when vaccination had been in use for only five years, it was stated in the public report of the hospital that "variolous inoculation" might be considered as generally superseded by the substitution of vaccination. Nevertheless, it must be recorded that the prejudice in favour of variolous inoculation was so great that at the hospital itself out-patient variolous inoculation was kept up for five years longer and in-patient inoculation for nearly twenty years—up to 1822. In 1813 the Royal College of Surgeons of England resolved that variolous inoculation was in future to be given up. Pressure was also applied to the Government to pass a law to forbid its practice, but without success. From this time, however, variolous inoculation gradually disappeared out of practice and vaccination became more general and more acceptable, so that in 1825 the medical officers of the Small-pox Hospital were able to report to Government that whilst the death-rate from casual small-pox in the unprotected was 41 per cent., in the protected it was but 8 per cent.

They also made much of the scar of vaccination as a sign of protection, and declared "that a perfect cicatrix should be distinctly defined, perfectly circular, indented, radiated, and not larger than the size of a common wafer. The diameter of the scar is, however, of less importance than its circular and well-defined edge." This description of a typical vaccination scar is so good that I have thought it worthy of repetition. I may say that it bears the stamp of Dr. Gregory.

In 1803 the Royal Jennerian Society for the Extermination of Small-pox was instituted in London in Salisbury-square, Fleet-street. It was founded at a meeting at the Mansion House held on Jan. 19th, 1803, and was patronised by the King and royal dukes.

I have before me the original instructions for vaccine inoculation as laid down by Jenner in 1801, as well as those published by the order of the Medical Council of the Royal Jennerian Society, which had Jenner at its head. I shall not weary you with reading them both, but those laid down by Jenner are well worth studying.

"INSTRUCTIONS FOR VACCINE INOCULATION, 1801.

"Let the vaccine fluid be taken for the purpose of inoculation from a pustule that is making its progress regularly and which possesses the true vaccine character, on any day from the fifth to the eighth, or even a day or two later, provided the efflorescence be not then formed around it. When the efflorescence is formed it is always most prudent to desist from taking any more of the virus from that pustule.

"To obtain the virus, let the edges of the pustule be gently punctured with a lancet in several points. It will gradually ooze out, and should be inserted upon the arm about midway between the shoulder and the elbow, either by means of a very slight scratch not exceeding the eighth part of an inch, or a very small oblique puncture.

"A little red spot will appear on the punctured part on the third day, if the operation succeed, which on the fourth or fifth becomes perceptibly vesicated. It goes on increasing till the tenth day, when it is generally surrounded by a rose-coloured efflorescence, which remains nearly stationary for a day or two. The efflorescence then fades away, and the pustule is gradually converted into a hard, glossy scab, of a dark mahogany colour. These progressive stages of the pustules are commonly completed in sixteen or seventeen days.

"A single pustule is sufficient to secure the constitution from the small-pox; but as we are not always certain the puncture may take effect, it will be prudent to inoculate in both arms or to make two punctures in the same arm, about an inch and a half asunder, except in very early infancy, when there is a great susceptibility of local irritation.

"If the efflorescence surrounding the pustule should be extensive, and occasion much local heat upon the arm, it may be cooled by the repeated application of pieces of folded linen dipped in cold water, or still more expeditiously by a strong solution of the aqua lithargyri acetati in water—an ounce, for example, of the former in five or six of the latter.

"If the scab should at any time be prematurely rubbed off, and not succeeded by another within twenty-four hours, the part may be occasionally touched with the undiluted aqua lithargyri acetati.

"Vaccine virus, taken from a pustule and inserted immediately in its fluid state, is preferable to that which has been previously dried; but as it is not always practicable to obtain it in this state, we are compelled to seek for some mode of preserving it. Various means have been suggested, but from the test of long experience it may be asserted, that preserving it between two plates of glass is the most eligible. Let a piece of common window glass be cut into squares of about an inch each, so that they shall lie smooth when placed upon each other. Let the collected vaccine fluid be confined to a small spot (about the size of a split pea) upon the centre of one of these glasses, which should be suffered to dry in the common heat of the atmosphere, without exposure to the heat of fire or the sun. When dry it should be immediately secured by placing over it the other piece of glass. Nothing more is necessary for its preservation than wrapping it in clean writing paper.

"The virus, thus preserved, when wanted for the purpose of inoculation, may easily be restored to its fluid state by dissolving it in a small portion of cold water, taken up on the point of a lancet. It may then be used in the same manner as when just taken from a pustule.

"The vaccine fluid is liable, from causes apparently trifling, to undergo a decomposition. In this state it sometimes produces what has been denominated the spurious pustule—that is, a pustule or an appearance on the arm not possessing the characteristic marks of the genuine pustule. Anomalies, assuming different forms, may be excited according to the qualities of the virus supplied, or the state of the person inoculated; but by far the most frequent variety or

Digitized by Google

deviation from the perfect pustule is that which arrives at maturity and finishes its progress much within the time limited by the true. Its commencement is marked by a troublesome itching, and it throws out a premature efflorescence, sometimes extensive, but seldom circumscribed, or of so vivid a tint as that which surrounds the pustule completely organised; and (which is more characteristic of its degeneracy than the other symptoms) it appears more like a common festering produced by a thorn or any other extraneous body sticking in the skin than a pustule excited by the vaccine virus. It is generally of a straw-colour, and when punctured, instead of that colourless, transparent fluid of the perfect pustule, its contents are found to be opaque. That deviation from the common character of the pustule, arising from vaccine virus which has been previously exposed to a degree of heat capable of decomposing it, is very different. In this instance it begins with a creeping scab of a pale-brown or amber-colour, making a long and slow progress, and sometimes going through its course without any perceptible efflorescence. Its edges are commonly elevated and afford on being punctured a limpid fluid.

"A little practice in vaccine inoculation, attentively conducted, impresses on the mind the perfect character of the vaccine pustule; therefore, when a deviation arises, of whatever kind it may be, common prudence points out the necessity of re-inoculation, first, with vaccine virus of the most active kind, and secondly, should this be ineffectual, with variolous virus. But if the constitution shows an insusceptibility of one it commonly does of the other.

"When any constitutional symptoms occur in inoculated cow-pox they are commonly first perceptible, especially in children, on the fourth or fifth day. They appear again, and sometimes in adults not unlike a mild attack from inoculated small-pox, on the eighth, ninth, or tenth day. The former arise from the general effects of the virus on the habit, the latter from the irritation of the pustule.

"If the effluvia of the small-pox have been received into the habit previously to the inoculation of the vaccine virus, the vaccine inoculation will not always be found to stop its progress, although the pustule may make its advances without interruption.

"The lancet used for inoculation should always be perfectly clean. After each puncture it is proper to dip it into water and wipe it dry. The practitioner should be particularly cautious in observing that its point be free from rust, either contracted by common means or from the action of the vaccine virus, which even when dry and in contact with it has a tendency in a little time to produce it.

"The preservation of vaccine virus upon a lancet beyond the period of a few days should never be attempted, as it is so apt to produce rust, which will decompose it.

"EDWARD JENNER."

This Royal Jennerian Society, however, soon got into trouble on account of certain irregularities of its local vaccinator, and in 1808 it ceased to exist. The Royal College of Physicians of London, by the command of the King, were consequently ordered to inquire into the state of vaccine inoculation in the United Kingdom and report their opinion and observations on that practice. This was accordingly done, and the Royal College, after a full and impartial investigation of the subject, made a report, dated July 8th, 1807, highly favourable to the practice of vaccination and strongly recommended its adoption. The report contained a recommendation that the poor should be encouraged to undergo the treatment by its being offered free of expense, with the hope that by such means vaccination would in time supersede inoculation for small-pox. To this recommendation the birth of the National Vaccine Establishment is to be attributed on June 22nd, 1808. The Home Secretary, then Lord Liverpool, having given his first instructions that the Royal College of Physicians should be consulted as to the most effective means of carrying into execution the resolution of the House of Commons respecting the formation of a National Vaccine Establishment, on Dec. 21st, 1808, a scheme was accordingly drawn up by the President of the College (Sir Lucas Pepys), in conjunction with Dr. Jenner and the Right Honourable George Rose, which received Lord Liverpool's approbation; and on Dec. 28th of the same year the President and Censors of the Royal College of Physicians of London and the Master and Governors of the Royal College of Surgeons of England constituted themselves into a board which met to carry out the scheme in a manner which should be satisfactory to the public and creditable to the high authorities under which they were to act. The work of the institution commenced in Leicester-square on March 11th, 1809; and by May 25th of that year—in the first ten weeks of its existence—732 people had been vaccinated and 2500 charges of vaccine fluid had been distributed. This movement was consequently the origin of our National Vaccine Establishment.

I have before me the first seventeen reports of the institution—the three first are written, the others printed—and it is pleasant to read in these pages of its steady success in all ways, although with successes came reports of reputed failures of vaccination and complaints of want of energy on the part of some of the members of our profession in spreading its blessings. In the report of 1820 some distinct and valuable recommendations as to the method of vaccinating were printed. The board thought it right to direct that lymph should never be employed from any vesicle in which the slightest irregularity or imperfection could be observed; nor even from a perfect vesicle after the areola had formed; that two punctures be made in each arm in order to secure at least three perfect vesicles; that one vesicle on each arm should be left unopened, and the lymph be suffered to be absorbed or desiccate. The board was earnestly desirous that more rather than fewer vesicles should be produced, and was of opinion that it was especially wrong to confide in one vesicle and highly imprudent to open all. I would wish you to remember that this board was made up of the President and Censors of the Royal College of Physicians of London and Master and Governors of the Royal College of Surgeons of England, Dr. Latham's name standing at the head. In the same year, 1808, there had lately been established by Government "a Board of Health to prepare and digest rules and regulations for the most speedy and effectual mode of guarding against the introduction and spreading of infection, and for purifying any ship or house in case any contagious disorder shall manifest itself in any part of the United Kingdom, and to communicate the same to all magistrates, medical persons, and others, His Majesty's subjects, who may be desirous and may apply to be made acquainted with the same." This report was drawn up with the view of preventing the introduction of the plague or other contagious and mortal distempers. It was hoped that this board would adopt the same rules with respect to persons affected with small-pox. This Board of Health was doubtless the beginning of our present Local Government Board, which in its maturity has but little likeness to its first ancestor; for whereas at its origin the rules and regulations against the introduction and spreading of infection were at the service of those who might apply to be made acquainted with them, all such are now made compulsory and under the control of specially educated scientific men under whom the great work of sanitary reform has so distinguished our age. The way in which cholera has been kept from our country in recent years is an object lesson which has well demonstrated the value of our present system.

In 1802 the House of Commons voted Jenner £10,000, and in 1807 £20,000 more, as a reward for his discovery; but this was not done without opposition and much worry to Jenner. Indeed, in 1801, when the subject of vaccination came before a committee of the House of Commons appointed to receive evidence of its value, Jenner wrote to Lady Berkely, his neighbour, "that he trusted that the committee would hear enough to remove all that nonsense which has crept into the brains of some of the sceptics, and be able to trace it to its true source, when it will appear to have sprung either from jealousy, as at Gloucester (near his home); from envy, as at Bristol; and from stupidity, as half the country over." In 1798, after the publication of his book, Jenner spent many months in London to demonstrate the truth of his discovery, yet during this time he was unable to prevail on one individual to submit to the operation of vaccination. Mr. Cline, the distinguished surgeon of Guy's and St. Thomas's Hospitals, did the first case in London in August, 1798, using some of the virus Jenner had given him. He, however, evidently did it with only half faith as to its specific virtue, for he used the vaccine upon a boy who had hip disease, under the theory that the counter-irritation excited by the cow-pox might prove beneficial to the disease. The vaccination, however, took well and went through its normal course, and the influence of this case and Cline's example in using the virus did much to encourage the introduction of vaccination. In 1821 Jenner still complained of the want of encouragement he received from his own people, and he always considered London to be the centre of opposition to the vaccine

Digitized by Google

practice. In a letter to his friend Gardner he alluded to a paragraph from Berlin in which some high mark of distinction was made to his name by a foreign nation when no marks at all had been made by that to which he belonged. He wrote: "Not only the people you see assemble to celebrate my name, but the Court itself through the proper officers. And why are all these attentions paid to me? For this plain reason: they see the truth of my original position that 'vaccination properly conducted (in such hands as their own, for example) is capable of banishing from their city, and I believe their empire, the small-pox—the severest scourge that ever spread its desolations among them.' The observation must not be confined to Prussia, as it will equally apply to the Continent in general. If any portion of the Continent has been more conspicuous than another in eradicating this poisonous weed it is Denmark, as we are told in a late publication that it is now (1821) eleven years since a single case of small-pox has been recorded in Copenhagen or indeed in any part of the Danish dominions, so strictly have the edicts of the Government been enforced respecting the prohibition of small-pox inoculation and the use of the vaccine only."

But time warns me that I must bring my observations to a close, for hitherto I have drawn your attention only to Jenner's work on the cow-pox and the influence it has had upon the world in supplanting variolous inoculation and doing much towards realising Jenner's hopes and stamping out small-pox altogether. That this result may come is quite possible if human effort continues to work in the right lines, but that we have not yet reached it experience too surely records. It may, however, be said with truth that small-pox is now, thanks to vaccination, a comparatively rare and certainly a somewhat unheeded affection; indeed, it has for some years been so lightly regarded by the public that vaccination has neither been rightly valued nor carried out with the care which is essential to bring about its full beneficial effects. The influence of the anti-vaccinationists and the delay in the publication of the report of the Vaccination Commission, which has been sitting seven years, have also probably had a pernicious effect upon the public, leading the ignorant and thoughtless to believe that the law of compulsory vaccination has been abolished or suspended, and that the Vaccination Commission itself is hesitating about pronouncing a definite opinion upon the value of the practice and in enforcing its general adoption. It is to be fervently hoped that the conclusions of this Commission will be clear and decided, and as there can be no open question as to the value of vaccination in suppressing small-pox, so there ought to be no question as to the expediency and justice of making it compulsory. The object-lesson now being so painfully given at Gloucester, near Jenner's own home, ought to be taken to heart by the country generally, and strengthen the opinions of those in authority who are the custodians of the public health: for it has made clear, to all who know what vaccination has done in the past to suppress variola, that where it has been so disgracefully neglected, as at Gloucester, it has proved as fatal as of old in at least one case out of every five attacked; and that small-pox unchecked by the only known available means of vaccination would soon re-assume its former power and become the same devastating and disfiguring scourge it was in the seventeenth century. For my own part I cannot do otherwise than regard Jenner—the discoverer and introducer of vaccination—as the greatest benefactor of the human race that this or any other country has produced, and I believe that the magnitude of this single act, which now seems to us so simple, has had its influence in leading the professional world to look upon Jenner himself as by no means so great a man as many others who have done less good work than he. In this opinion I am sure the world has been entirely wrong, for no one can read his life as written by Baron—though not in a very happy vein—or read the many letters of his which are now in the Hunter-Baillie collection and not feel that Jenner possessed the true Hunterian characteristics; that as an observer he was quick, deep, and accurate; as a worker, untiring and zealous; as an experimenter, careful and precise; and as a thinker, of the highest and clearest kind. Cautious almost to a fault, he, like Hunter, postponed the publication of his thoughts and discoveries until there was no room for doubt as to their truth, so that in 1823, a few days before his death and twenty-five years after he had given his great discovery to the world, he could write: "My opinion of vaccination is precisely as it was when I first promulgated the discovery. It is not in the least strengthened by any event that has happened, for it could gain no strength. It is not in the least weakened, for if the failures which have been reported had not happened the truth of my assertions respecting those coincidences which occasioned them would not have been made out." And now, nearly a century later, we his successors can endorse these views, for no flaw has yet been found in Jenner's discovery, or in his recognition of the value of re-vaccination. I could say much in support of my opinion of Jenner's general character, but time forbids, and I cannot do better in closing this address than quote some words from an autobiography of his intimate friend Mr. Gardner, commenced about 1810, this gentleman having been a man of literary tastes living at Frampton, near Gloucester. "In the year 1780," wrote Gardner, "I fortunately became acquainted with that luminary in philosophy and in the art of medicine, Dr. Edward Jenner, since the celebrated discoverer of the vaccine inoculation. I was so much flattered by him that I ranked amongst the first friends of his early youth. I reflect upon the hours, the days, the weeks, the months, and the years which I spent in his society as the happiest in my life. How often have I dwelt with silent attention upon his profound remarks upon various subjects of natural philosophy, particularly those of a physiological kind, and how frequently have I witnessed his skill displayed in the various parts of his profession. Honoured with this gentleman's friendship I have passed more than thirty years of my life and intercourse equally instructive and delightful. No man, I should suppose, has known Dr. Jenner more than myself, and to know him is to know everything that is excellent in human nature. His skill in his own profession has long been acknowledged and has been by the learned world justly appreciated. The genius of Jenner was formed by nature for higher pursuits than the medical art. He was the poet, 'poeta nascitur'; that gift divine so rarely bestowed upon man was given to him, and though his unremitting ardour in the pursuit of natural history and his attention to the duties of his profession prevented him from the frequent exercise of his talent for poetry, yet the fire, in some measure extinguished but not smothered, sometimes burst out. He was peculiarly happy in epigram. Dr. Jenner, so eminent as he is by his natural and acquired endowments, by a sort of singular composition of character has not lost any of those soft amenities which polish the surface of human life. In him was always perceived the gentleman of polite and elegant manners which gilded over the profundity of his philosophic remarks. Nothing harsh was ever found in Jenner, and were I inclined to censure any part of his conduct it would be his too ready acquiescence with the sentiments of some of his associates, however absurd; but this was the acquiescence of philanthropy. As the discoverer of the vaccine inoculation we behold him for a series of years unremittingly pursuing the grand object which he had in view, undismayed by prejudice and only smiling at the assaults of ignorance. Shielded by his good sense from the shafts of envy, he consigned to posterity (that certain judge of merit in every branch of science) the eulogium of his genius and his labours. With this distinguished character I have in the social intercourse of uninterrupted friendship spent more than thirty years of my life; in his company I have experienced some of the happiest days of my existence. He was my guide, my counsellor, and my friend. Language can go no further." Nor, may I add, is any addition wanted, for such testimony as I have read from a lifelong friend of Jenner and which was not written for publication bears the stamp of truth upon it. It remains for us, therefore, to recognise the claims of Jenner upon the admiration and gratitude of humanity, and as Englishmen to be proud of the distinction which his immortal discovery has conferred upon us. Let us keep in mind the opinion of Professor Virchow, speaking as an ethnologist in Berlin on May 14th, 1896, that "all the peoples that had not been reached by vaccination, or that had not accepted it, had disappeared from the face of the earth destroyed by the small-pox"; with that of M. Hervieux, who, on May 12th, 1896, in an eloquent address upon Jenner delivered before the Académie de Médecine in Paris, said:—"Resting on the triple base of animal vaccine, re-vaccination, and compulsion, this power is sufficient to defy all the assaults of small-pox, and may be proclaimed to be the grandest conquest of medical science." But our gratitude and pride must not stop here, for Jenner by his methods of investigation pointed out to scientific men a new direction in which future triumphs were to be won, and which in the

Digitized by Google

hands of our best scientists already promises to be productive of untold value. The results of their work and consequently of Jenner's work cannot yet be fully estimated, but the light which has been thrown by Pasteur and his co-workers—when working in Jenner's line—upon the causes of specific diseases and the means of fighting them has encouraged the most hopeful of us to expect that many, if not all, of the contagious diseases with which we are now afflicted may in the near future be as much under human control as small-pox is now known to be, and that the development of Pasteur's work in the direction which has been so skilfully worked out by Sir Joseph Lister may in the future be productive of as much good as it has already proved to have been in the past. Let us, then, cherish these memories and encourage such labours and be careful whilst we do so not to lose anything of their value by carelessness or indifference.

The Croonian Lectures:

A CONTRIBUTION TO THE STUDY OF THE BLOOD AND OF THE CIRCULATION.

Delivered before the Royal College of Physicians of London,

BY GEORGE OLIVER, M.D., F.R.C.P. LOND.

LECTURE IV.[1]

Delivered on June 11th.

MR. PRESIDENT AND GENTLEMEN,—During recent years observers have found that the percentage of the hæmocytes is considerably affected by altitude, baths, massage, and by surgical interference, such as opening the abdomen and section of the cord.[2] Certain theories have been suggested in explanation of these variations, and it will be convenient to refer to them now, as a whole, before dealing with the results of further observation by means of the new modes of rapidly determining the corpuscles and hæmoglobin described in the last lecture. They may be broadly divided into two classes—namely, those which refer the increase or the reduction of the percentage of the chromocytes either to (1) the corpuscles themselves or to (2) variation in the quantity of water in the plasma.

I. *Theories associated with the corpuscles.*—Three such have been suggested—namely, (1) formation and destruction of corpuscles, (2) dislodgement of resting corpuscles, and (3) transference of corpuscles.

1. The formation and destruction of corpuscles. Whenever a marked increase of the number of the corpuscles has been observed, as in high altitudes, the first adopted theory has almost invariably been that of increased formation.

2. Dislodgement of resting corpuscles has been advanced in explanation of the effects of massage.

3. The transference of corpuscles from the arteries to the capillaries and *vice versâ* was suggested by Cohnstein and Zuntz[3] in explanation of the variation in the number of the corpuscles which they observed in the arteries on the one hand, and in the capillaries on the other, as the result of experiments on animals. These observers found that the proportion of the corpuscles to the plasma was definitely varied in the large vessels and in the capillaries by cutting the cord, by electrically stimulating the cut cord, and by other procedures, and they concluded that the capillaries are normally poorer in corpuscles, and therefore richer in plasma, than the larger vessels, that when the arteries leading to the capillary field are contracted the blood in that field becomes still poorer in corpuscles and that elsewhere still richer, and that when the arterioles are dilated the capillary blood contains a larger proportion of corpuscles, and the plasma previously present in it in comparative excess is now distributed and dilutes the rest of the blood. According to this theory widening of the arterioles and filling of the capillaries produce the same effect on the blood of the large vessels as resorption fluid and narrowing of them as increased filtration.

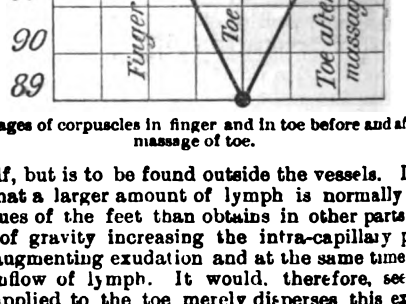
II. *Theories founded on alterations in the proportion water in the plasma.*—An apoplasmic state of the blood been referred to (1) increased transudation from capillaries; and (2) increased discharge of water from kidneys, skin, and mucous membranes.

1. Increased transudation from the capillaries. Regèc Brasols,[5] Klikowitsch,[6] and others refer peripheral change the circulation to disturbance of the equilibrium betw filtration on the one hand and resorption on the other, the adjustment of the normal balance to the operation these forms of transudation. Though this theory does explain the variations that take place in the periphe vessels, it is nevertheless not at all improbable that a exudation of watery fluid from the capillaries plays a m important part in the temporary and quickly induced alte tions of the blood which result from all forms of exerci and Professor Sherrington refers the striking reduction the plasma which he has observed as the consequence setting up local inflammation in animals to "increa exudation through the vascular membrane in the inflam area."[7]

2. Increased discharge of water from the kidney, skin, a mucous surfaces is an undoubted cause of apoplasmia various physiological and pathological conditions presen to be referred to. The following observations mainly s port the theories founded on fluid-transfer from the blo and do not corroborate those relating to the formation a destruction or to the dislodgement and transference corpuscles.

I. *The blood derived at the same time from different pa of the body* does not always afford the same percentages corpuscles and hæmoglobin. A large number of observatio were made on subject A. with the invariable result that t blood furnished by the toes was much poorer than th afforded by the fingers. This disparity does not seem to the same in all individuals, for in subject B., w possesses a higher arterial pressure, it was less appare It does not, however, follow that the blood present the vessels of the parts in question is actually differe in quality, for it has been repeatedly found th when the toe, which yielded a sample of very inferi quality, was well rubbed it furnished another quite co parable with that derived from the finger (Fig. 19).[8] Pr bably, therefore, the cause of the difference is not in t

FIG. 19.



Percentages of corpuscles in finger and in toe before and after massage of toe.

blood itself, but is to be found outside the vessels. It is unlikely that a larger amount of lymph is normally pres in the tissues of the feet than obtains in other parts in c sequence of gravity increasing the intra-capillary press and thus augmenting exudation and at the same time retar ing the onflow of lymph. It would, therefore, seem t massage applied to the toe merely disperses this excess tissue lymph and enables the observer to ascertain quality of the blood as it actually exists in the vess Exactly the same thing is not infrequently observed ansæmia, the percentage of the corpuscles and hæmogl rising very considerably after the application of massage a few minutes to the finger. Probably, therefore, there often, if not generally, an excess of tissue fluid even in finger in ansæmia, and consequently in this condition

[1] Lectures I., II., and III. were delivered on June 2nd, 4th, and 9th, and published in THE LANCET of June 6th, 13th, and 20th respectively.

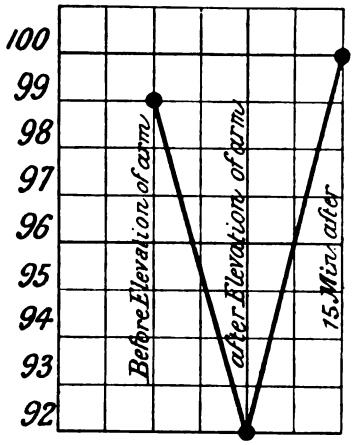
Digitized by Google

sample of blood obtained in the ordinary way without previous massage does not always afford a true reading of the actual state of the blood. The existence of this diminutive degree of œdema in the insufficiently nourished tissues of the anæmic is, moreover, rendered probable by the experiments of Lazarus-Barlow. This observer says: "This explanation of œdema as the result of anæmia I have confirmed in the following way. By means of an Esmarch's bandage I rendered the limb of a dog bloodless, while at the same time, of course, most of the lymph was removed from the part. After keeping the limb thus anæmic for from two to three hours I removed the bandage, and now by means of the specific gravity method I found that œdema came on. The arterial blood rose in specific gravity; the blood in the femoral vein rose in such a way as to show that more fluid was being lost during the passage through the limb than normal; and the muscles and skin fell in specific gravity. Starvation of the tissues, therefore, plays an important part in the causation of passive œdema."[9]

II. *Posture.*—The remarkable effects of gravity on the composition of the blood is well illustrated by passively elevating a limb (arm or leg) for fifteen minutes. Figs. 20 and 21 show that the percentage of the corpuscles is thus markedly reduced. This result was invariable in both subjects. It will be observed (Fig. 21) that even the blood derived from

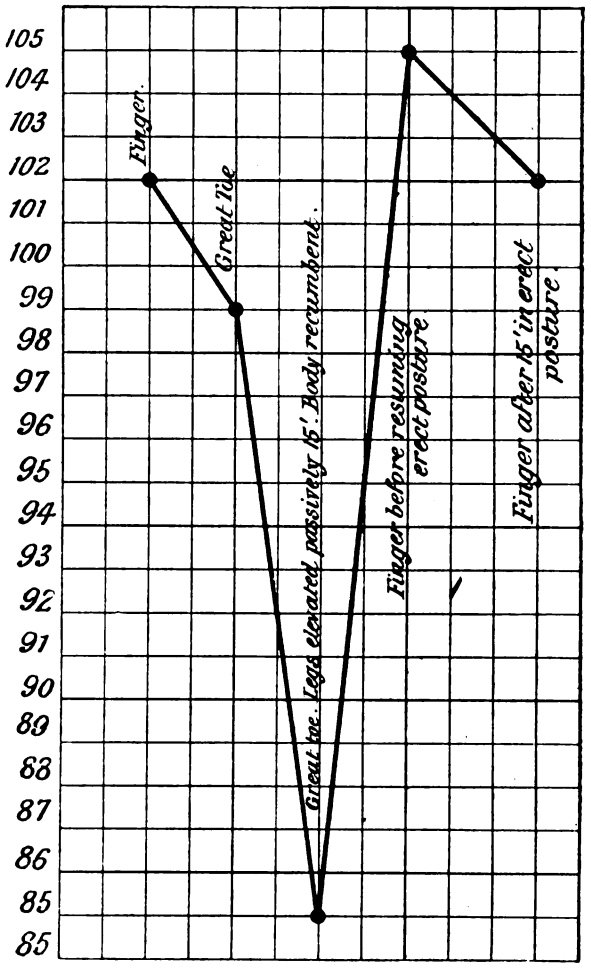
FIG. 20.



Percentages of corpuscles before and after passive elevation of arm.

the great toe, which is poorer in corpuscles than that of the finger, becomes still poorer after passive elevation of the leg for fifteen minutes, and that the blood afforded by the finger before resumption of the erect posture acquires a higher percentage of corpuscles than was present before the legs were elevated. These alterations in the proportion of the corpuscles is much in keeping with the effects of gravity on the blood pressure described in the first lecture. (Fig. 21.) It was then shown that when the legs were passively elevated the radial pressure was considerably increased, and that the passive elevation of a limb above the level of the arch of the aorta reduces the arterial pressure in that limb. It may, therefore, be inferred that the variations in the percentage of the corpuscles are in keeping with similar alterations in the intra-capillary pressure; that when there is an increase in both (as in the recumbent parts) there is probably augmented normal exudation; and when there is a reduction (as in the elevated limb) there may be an arrest of normal exudation or probably there is an osmotic inflow of tissue-fluid into the blood through the capillary wall.[10] According to the theory of Cohnstein and Zuntz[11] the diminution of corpuscles in the elevated limb should be referred to an increase of the normal disproportion between the plasma and the corpuscles in the capillary area, and the augmentation of them to a removal or diminution of that disparity as a result of the opening up and the extra filling of the peripheral vessels of the recumbent parts. Whichever theory be accepted the fundamental position remains that the alterations in the

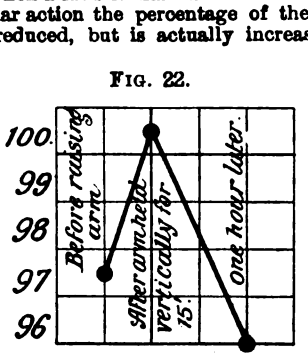
FIG. 21.



Percentages of corpuscles in finger and toe. Effect of posture. Legs elevated with support.

blood are closely associated with similar differences in the intra-capillary pressure; and this is further illustrated by the fact that when a limb is maintained in the vertical position by muscular action the percentage of the corpuscles is not only not reduced, but is actually increased (Fig. 22).

FIG. 22.



The percentages of corpuscles in the finger before and after raising the arm vertically by muscular effort fifteen minutes.

Fig. 23 further illustrates this fact, for it shows that elevation of the leg by muscular effort may raise the percentage of corpuscles in the blood of the toe to that of the finger, and that on passively maintaining the position of the limb

[9] The Pathology of Œdema, Brit. Med. Jour., 1895, vol. i, p. 635.

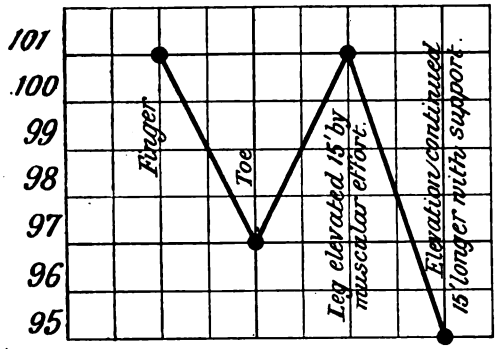
[10] Dr. Starling's experiments support this explanation. "Whereas capillary pressure determines transudation the osmotic pressure of the proteids of the serum determines absorption. With increased capillary pressure we shall have increased transudation until we get equilibrium established. ..... With diminished capillary pressure there will be an osmotic absorption of salt solution from the extra-vascular fluid until this becomes richer in proteids."—The Arris and Gale Lectures, THE LANCET, May 16th, 1896.

[11] Op. cit.

Digitized by Google

the usual fall of the percentage then takes place. From these observations it would seem that the intra-capillary pressure of the elevated limb is not only prevented from falling, but is increased by the afflux of blood which occurs when the muscles are brought into play, and that when the muscular action is withdrawn and the vertical limb is passivly supported the intra-capillary pressure promptly falls. These observations on the influence of gravity on the composition of the blood and the thwarting of that influence

FIG. 23.

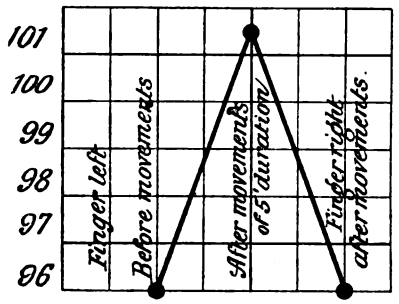


Percentages of corpuscles in finger and in toe before and after active followed by passive elevation of leg.

by muscular action illustrates the wisdom of passively supporting a part when in a state of inflammation or inflammatory congestion, for such a procedure not merely tends to reduce the blood pressure, but to diminish the percentage of the corpuscles also.

III. *Exercise.*—The effects of local exercise on the relations of the red corpuscle will be considered before those of general exercise. *Local exercise* may be active or voluntary, as when the hand is flexed and extended on the forearm until fatigue is induced, or when the muscles of the arm are thrown into a state of tonic contraction, as in the resistive movements, or it may be passive as when produced by faradism or massage. It has been found that muscular action, however induced, causes an immediate decisive and proportionate rise in the percentages of the corpuscles and the hæmoglobin. Fig. 24 illustrates this effect produced by

FIG. 24.

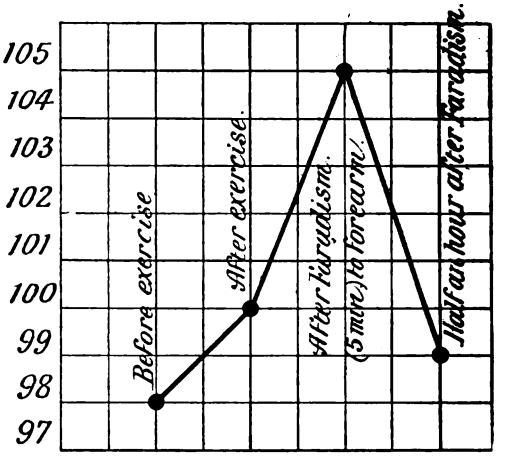


Percentages of corpuscles before and after local exercise.

flexion and extension of the forearm, and the same result is induced by resistive movements, by massage, and by faradism. Fig. 25 shows that the rise caused by local exercise may be extended by faradism. In all cases the increased percentage of the corpuscles was purely local, for at the termination of the procedure the blood yielded by the opposite finger presented the same proportion of corpuscles as was observed before the muscles were brought into action. Though the rise was rapid it did not subside so quickly, for the disappearance of it generally required from thirty to sixty minutes, and in the case of massage it lasted longer than after voluntary exercise or faradism. It was observed that galvanism of the forearm (contraction of the muscles being avoided) and faradism of the finger and massage of the finger[12] did not disturb the reading of the corpuscles. The invariable antecedent of the rise of the corpuscles was either muscular contraction or manipulation of the muscular tissue, which in producing this effect is equivalent to muscular contraction. Inasmuch as the rise in hæmoglobin is proportionate to that of the corpuscles, this common effect of active and passive exercise of the muscular tissue for short periods is obviously due to an increased proportion of chromocytes to the plasma. How is this temporary and strictly local apoplasmia produced?

In the first lecture it was pointed out that there was some probability in the view that the increased volume of blood

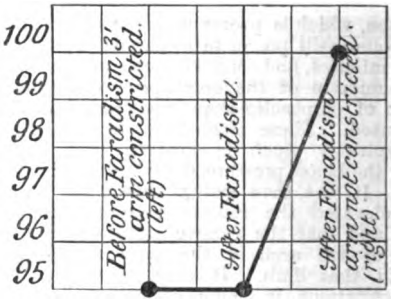
FIG. 25.



Percentages of corpuscles before and after local exercise and after faradism following the exercise.

which circulates through the muscular tissue when brought into action, and the consequent increase of the intra-capillary pressure within that tissue, may lead to the effusion of watery fluid from the blood into the substance of the muscles. But inasmuch as the blood-supply of the finger is not immediately connected with that of the muscles it is difficult to see how muscular exercise can thus affect the blood in the finger. This, however, is not the only explanation available, for it is known that in a state of rest there is no lymph-flow at all,[13]

FIG. 26.



Percentages of corpuscles before and after faradism with arm constricted and non-constricted.

and that muscular contraction is necessary to propel the lymph from the lymph spaces into the lymphatics; therefore, when all the muscles of a limb are thrown into action there will be an immediate acceleration of the circulation of lymph from the whole limb, including a considerable area of non-muscular tissue, accompanied by an augmented exchange of fluid from the blood to the tissues (non-muscular as well as muscular). The muscular action of a limb, therefore, accelerates the circulation of all the fluids in the limb, and the increased intermediary transfer of fluid from the blood through the capillary wall to the lymph spaces and from these to the lymphatic vessels must reduce the volume of the plasma in all the vessels of the limb. There is one experiment recorded which may have a bearing on this explanation (Fig. 26). The left arm was

[12] This observation only holds good when the circulation is normally vigorous, for when it is enfeebled, and especially when the blood is poor in corpuscles and hæmoglobin, massage of the finger may produce a marked rise of the chromocytes.

[13] Starling, op. cit.

Digitized by Google

firmly constricted above the elbow, but not so constricted as to affect the pulse, and the muscles of the forearm were thoroughly faradised for three minutes; but the blood drawn from the left forefinger afforded no evidence of change. Faradism was then applied in exactly the same manner and duration to the right forearm free from constriction, and the blood of the right forefinger showed the usual marked rise of corpuscles. The inference seems to be that in the former case the lymph-flow was arrested by the constriction and the accumulation of tissue fluid nullified the rise of the corpuscles. Moreover, when treating on general exercise an observation will be adduced which shows that exercise does cause an increased transfer of fluid to the tissues, which, however, lodges in a limb until it is removed by massage or by muscular contraction. Cohnstein and Zuntz might refer this effect of muscular contraction on the blood to the increased filling of the whole peripheral area of the exercised part—the normal relative excess of plasma in that part being thus diminished. But later it will be shown that when the non-muscular part of the periphery is well filled by the agency of warmth the corpuscles are found to be reduced. All the facts seem to be best explained by the view that muscular contraction stimulates the circulation of all the fluids and aspirates, as it were, the lymphatics of the non-muscular and remote parts of the limb, and thus reduces the storage of tissue lymph in them. Moreover, this view explains to a large extent the wide-reaching effect of exercise on the nutrition of all the tissues by promoting that most important part of the circulation of fluids, the intermediary circulation. In this way, in all probability, some of the benefit which is derived from modulated movements, such as the resistive exercises, is to be explained.

Since these observations were made I find that Chéron has observed that massage, dry friction, and electricity will within ten minutes greatly increase the number of the corpuscles—in one case of anæmia raising it from 2,430,000 to 4,080,000 per c.mm. He also attributes the rise to concentration of the blood from increased transudation of fluid which results from augmentation of the blood pressure.[14] After an hour's massage J. Mitchell noticed an increase of the chromocytes which attained its maximum an hour after the cessation of the process, but without a corresponding rise in the hæmoglobin. He explains this anomaly by suggesting that massage may dislodge a number of corpuscles poorer in hæmoglobin than those in circulation which were resting in various parts of the body.[15] So far I have not met with any corroborative evidence of this observation or of this suggested explanation of it. It is but natural that those who have observed the blood before and after massage should dwell on the immediate effect as evidence of the benefit at once conferred by the procedure. It is well, however, to keep in mind that the observed alteration in the blood is merely an indication that the massage, like exercise or faradism, has advanced the onflow of tissue fluid and has increased the transudation of fluid from the blood, so that this for a time is poorer in water and therefore richer in corpuscles. In anæmia it is highly probable that the repeated stimulation of the intermediary circulation by massage will eventuate in an improvement of the blood, but only because, like other forms of exercise of the muscles, it raises the nutrition of all the tissues.

General exercise.—In animals it has been observed that active exercise produces an increase in the percentage of the corpuscles and hæmoglobin and a fall in the blood-decimal. For instance, an hour's run in a dog that had been kept in the laboratory for several weeks raised the corpuscles from 99·5 per cent. to 110 per cent. and the hæmoglobin from 104 per cent. to 109 per cent., and reduced the blood-decimal from 1·04 to 0·99. It has been shown by Löwit that binding down and tying of animals, especially when long continued, induce severe changes in the composition of the blood.[16] I have observed that the struggling of a rabbit for merely a few minutes (as when the animal is carried by the ears or is tied up) will impair the validity of the results of any observations of the blood made for specific purposes. For instance, in one case before such strenuous muscular effort the corpuscles read 92 per cent., but immediately after it 110 per cent., and in ten minutes afterwards 105 per cent. Therefore, it would seem that profound (though temporary) alterations in the blood are immediately induced by very active general muscular action.

In attempting to determine the effects of general exercise on the blood it is difficult to eliminate the rise in corpuscles due to perspiration. The general results, however, of the observations already made may be stated to be a rise in the corpuscles, which after a variable period somewhat subsides, but remains above the initial percentage while the exercise lasts, and a similar though diminished rise and reduction of the hæmoglobin percentage. The rise in corpuscles and hæmoglobin produced by an hour's active walk generally subsides after an hour's rest. The immediate effect of general exercise on "the worth" is to reduce it, and the remote effect—observed after the lapse of some hours—is to increase it.[17] It would seem that in general exercise there are the same increased transfer of fluid from the blood and the same augmented lymph-flow as take place in local exercise; but the concentration of the blood thus induced is after a time somewhat lessened by the return of a portion of that fluid to the blood. It was found that when an arm is slung at rest and without constriction during exercise the volume of the limb increases and the blood yielded by the finger falls in corpuscles while that afforded by the free and exercised arm rises, and then when the finger of the passive arm is well rubbed upwards and rolled for a few minutes it furnishes a sample equally rich in corpuscles as in that obtained from the opposite finger. This observation was repeated in two subjects who ascended the Schatzalp (1020 ft.) at Davos, and as the results were the same in both it is only necessary to give the figures furnished by one of them. On return from the ascent the blood from the finger of the slung arm contained 3 per cent. fewer corpuscles and that from the opposite finger 5 per cent. more than on starting out, and after massage of the former finger the corpuscles rose 8 per cent., so that now they read exactly the same on both sides.[18] This observation shows that in the non-exercised limb the tissue fluid was increased, probably from the rise in blood pressure resulting from the general exercise, but in the absence of muscular contraction it was not removed from the tissues as in the exercised limb, so that the blood issuing from the finger of the passive arm was diluted by it until it was dislodged by massage, when the true state of the blood was ascertained—namely, a rise in corpuscles equal to that observed in the exercised limb. Probably the effect of general exercise is modified by the amount of tissue lymph present when the exercise is taken. In those, for example, who do not take exercise habitually or in whom the circulation is languid or the blood poor the lowered intermediary circulation favours the storage of tissue fluid, and exercise may even fail to incite a rise in the corpuscles. On the other hand, those accustomed to regular active exercise have a smaller storage of tissue lymph, good percentage of corpuscles and hæmoglobin, and a permanently high specific gravity of the blood.[19]

IV. *Digestion.*—Observation of the effects of ninety-six meals (breakfast, lunch, and dinner), each having an average supply of seventeen ounces of fluid, shows that, as a rule, in from two to three hours the percentages of the corpuscles and hæmoglobin fell in 70 per cent., rose in 23 per cent., and were without change in only 7 per cent. The evidence, therefore, preponderates in favour of a fall of the chromocytes[20] and hæmoglobin during digestion. The average "worth" showed but little alteration, for in 53 per cent. of the observations it slightly fell, while in 47 per cent. it either rose or presented no variation. Two other facts were also very frequently apparent—namely, a preliminary and very transitory rise shortly after the meal and a rise with slight gain in "worth" subsequent to the lowest point of the fall. These stages of the effect of the digestive process on the blood taken from the systemic periphery are probably the resultants of several causes, of which perhaps the most prominent may be fluid transfer and the hæmolytic and hæmopoietic functions of the organs accessory to primary digestion. The preliminary rise may be due to the copious

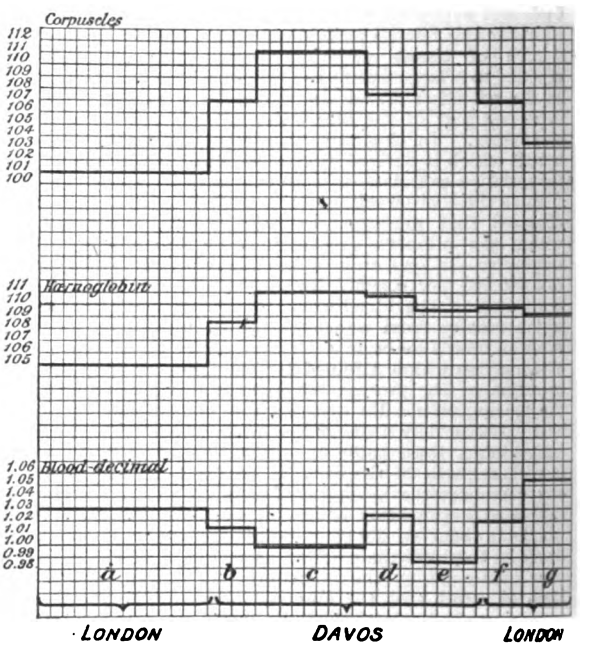
Digitized by Google

outpouring of the digestive juices. But this effect is so transitory that it may be easily missed, even though the meal is a solid one; therefore, it would seem that it is quickly compensated, either by the absorption of fluid, as from the tissues, or perhaps by a cytolytic process. The digestive fall appears to coincide with an increase in the volume of the blood and with a reduction of the specific gravity as observed by Lloyd Jones, and the subsequent rise with a reduction of the blood volume through renal elimination and a corresponding increase of the specific gravity.[21] It has been observed that these variations are not caused by the water taken with the meals, for they are quite as pronounced when it is withheld. Time and opportunity have so far failed me to ascertain the effects of certain diets on the blood decimal—such as one exclusively vegetable or animal (e.g., red meat and hot water, the Salisbury diet) and the osmotic effects of water and especially of mineral waters.

V. *Altitudes*.—The remarkable effect of altitude in raising the percentage of the corpuscles and hæmoglobin has furnished one of the most interesting physiological problems in relation to the blood—a problem which has of late years attracted many observers, who have now collected a fairly large body of data with a view to its solution. All these observers (including Viault,[22] Egger,[23] Mercier,[24] Von Jaruntowsky and Schröder,[25] Miescher,[26] Wolff and Koeppe,[27] are perfectly agreed as to the facts—namely, the presence of a larger number of hæmocytes in the inhabitants of mountainous regions than in the residents of lower altitudes, and a rapidly induced increase of them in those of the latter who resort to the mountains—an increase which, however, as rapidly passes away when they return to the plains. Among the residents Viault enumerated 8,000,000 per c.mm. on the Cordilleras (14,274 ft.) and Egger, 7,000,000 per c.mm. at Arosa (6100 ft.) in Switzerland. It has been observed in those who visit the higher levels that the increase begins shortly after arrival. Egger estimates that in healthy subjects it amounts to 702,000 and in tuberculous subjects 982,000 per c.mm. in fourteen days. Wölff and Koeppe at Reiboldsgrün (2257 ft.) observed that in from twenty-four to thirty-six hours after arrival an average rise of 1,000,000 per c.mm. takes place, and this is followed, first by a decline, and then by a further increase, until an average of 5,970,000 per c.mm. is attained. They found, moreover, that the proportionate hæmoglobin at first fell and afterwards rose. Von Jarnutowsky and Schröder at Görbersdorf (1740 ft.) observed the same fact; and, moreover, found that mild phthisical cases acquired a larger number of corpuscles per c.mm. than are present in healthy persons in the same altitude, and that severe cases attained even more than are generally found in normal individuals residing in lower parts. The lessening of the percentage of the hæmocytes on return to the valleys and plains is just as rapid as is the increase produced by visiting the higher altitudes. Miescher gives an example of the progressive daily fall of 250,000 per c.mm. for a series of six days, so that in this case at the expiration of this short period 7,200,000 per c.mm. on leaving Arosa were reduced to 5,700,000. With the view of observing for myself this interesting effect of altitude I spent twenty-three days at Davos Platz (5200 ft.) last month. Exactly the same mode of life was there followed as in London in regard to exercise, &c. The leading results are shown in the annexed diagram (Fig. 27), in which the night and morning observations are averaged for certain periods—namely, (*a*) fourteen days preceding the visit (affording the basis of comparison), (*b*) the first four days of the visit, and (*c*) the ten following days during which the daily consumption of water was the same as in London, (*d*) four days in which it was increased (from fifty to seventy-five ounces), (*e*) five days in which it was again the same, (*f*) four days, and (*g*) five days after returning to London. The corpuscles began to rise within twenty-four hours and attained their maximum percentage within the first week. The average increase during the second portion of the visit (*c*) was 10 per cent. and the maximum rise 14 per cent. The hæmoglobin increased, but in a less degree than the corpuscles. Consequently the blood-decimal fell from 1·03 to 0·99; when, however, the consumption of water was increased and the corpuscles were reduced in number it rose to 1·025, and when the ordinary quantity of water was was resumed it again fell.

There is another fact strikingly apparent in the Davos observations—namely, the greatly reduced range of the night and morning variations of hæmoglobin and of the corpuscular worth, and particularly the latter. Whereas in London they varied 9 per cent. and 0·05 respectively, at Davos they were reduced to 4·2 per cent. and 0·02. The night and morning variations of the corpuscles were only slightly diminished (from 2·9 to 2·4 per cent.). It therefore follows that though the night and morning worth was reduced the hæmoglobin was more uniformly distributed over the twenty-four hours at Davos than in London and the worth during the day was approximated to that of the night. After leaving Davos the corpuscles fell much more slowly than after arrival, and the hæmoglobin remained at much the same level as during the visit; hence the blood-decimal rose, and, indeed, advanced beyond the degree present in London

FIG. 27.



The percentages of corpuscles and hæmoglobin and the blood-decimal at Davos Platz and in London before and after the visit.

before the visit. This after-effect would seem to show that Davos has impressed the blood most favourably, notwithstanding the fall of the blood-decimal during the immediate influence of the altitude. The question arises, Would this gain in value have taken place at Davos had the visit been prolonged? On return to London the night and morning variations in hæmoglobin and worth again widened as before. I am hoping to make another and a longer series of observations on the effects of altitude on the blood. In explanation of the facts there is a somewhat remarkable agreement among the different observers. They all regard the increase of the chromocytes as due to rapid construction incited by lessened supply of oxygen from the reduced pressure, and they believe that it compensates for the deprivation of oxygen. Recently Grawitz has criticised this position and has shown it to be untenable.[28] He points out that the experiments of A. Fränkell and Gepert, in which dogs were subjected to an atmospheric pressure equal to that of an altitude of 16,000 ft., show that the blood contains at that greatly reduced pressure as much oxygen as at the ordinary pressure. Therefore it would seem that in altitudes below 16,000 ft. there does not exist a need for a compensatory increase of the chromocytes.

Besides this, the theory of new formation is highly improbable from the extreme rapidity of the rise, and from its

Digitized by Google

being still more rapid and greater in the phthisical than in the healthy. Moreover, when on returning to lower levels the percentage falls there are no signs of wholesale destruction of chromocytes, such as hæmoglobinuria, icterus, and bilirubinuria. The observers have described the appearance of a number of small forms in the blood after seven or eight days which they regard as young chromocytes; and as they assert that these increase in number as the ordinary regular sized corpuscles decrease, they conclude that during the first week the old corpuscles undergo destruction and new ones are formed. Grawitz, on the other hand, believes that this microcytosis arises from the lessening of the red discs in consequence of the loss of water, there being a diminution and a concentration of the serum (oligoplasmia) from the same cause. I am inclined, however, to doubt if this explanation of Grawitz will account for the appearance of the microcytes, for shrinking of the chromocytes from loss of water would probably lead to alteration in their appearance, such as crenation, which would scarcely escape observation. The blood was frequently observed during my visit; but the presence of microcytes was never detected, nor were any changes observed in the appearance of the corpuscles. Perhaps the microcytes described by previous observers were such as are met with in anæmia. It is obvious that this is a matter requiring further observation. Grawitz points out that the investigators who held the view of the new formation of corpuscles have not mentioned the presence of nucleated red discs and the increase of leucocytes which are generally met with when the blood-cells are being formed after hæmorrhages, &c. He refers the solution of the problem to increased loss of water from the blood through the skin and respiratory tract in consequence of the great diminution of humidity in the atmosphere. There are many facts in support of this view. Meteorologists find that the reduction of humidity is more rapid than that of the atmospheric pressure, and certainly a fall of from 40 to 50 per cent. of the absolute moisture present on the sea-level must greatly increase the abstraction of water from the blood by transpiration through the skin and the oro-respiratory mucous membrane. Though this explanation is highly probable it would, I think, be more conclusive were it proved that the corpuscles rise in number in places equally dry near the sea-level, such as Egypt. At the same time also we should not overlook the fact that high altitudes may perhaps favour polycythæmia in another way. In the first lecture it was shown that deep breathing raises arterial tension. The rarified air of mountain climates is known to induce deeper breathing, and, in consequence, to increase the circumference of the chest from one to three inches.[29] Shortly after arriving at Davos it was observed that my arterial tension was raised and continued to be raised throughout the visit, for the radial pressure and calibre were increased, the former being from 20 to 30 mm. of Hg., and the latter from two to three points higher than in London, and, moreover, the postural variation was reduced from one to three points. All these signs of increased arterial tension gradually subsided after leaving Davos.

Some facts were adduced in the second lecture which favour the view that increased intra-capillary pressure augments transudation from the blood, and later other data will be referred to which point to increased arterial tension as a common cause of apoplasmia by raising the excretion of water. It would, therefore, seem probable that two factors combine to produce the polycythæmia in question—namely, increased transpiration of water from the dryness of the air[30] and increased arterial tension from the reduced atmospheric pressure. When the consumption of water was increased (Fig 27) the operation of the first cause was, at any rate in some degree, counteracted and the corpuscles fell 3·5 per cent., still there remained a rise of 6·5 per cent., which was probably largely due to the increased arterial tension produced by altitude. From the facts observed it may therefore be concluded that the physiological effect of altitude on the blood is to raise the percentage of the corpuscles more than that of the hæmoglobin and thus to reduce the blood-decimal, and that this reduction may be counteracted by the increased consumption of water. This fact is in the main in keeping with my clinical observation of apoplasmia, for it has been almost invariably observed that when the percentage of the corpuscles is increased beyond the normal that of the hæmoglobin is not raised in proportion, and therefore the blood-decimal falls, and that when the supply of water is increased the corpuscles fall in number and rise in value. The wherefore is not obvious, but repeated observation has shown that water in some way raises "the worth" when an undue proportion of corpuscles exists, and that it is of undoubted value in the treatment of apoplasmic anæmia to be referred to later. Dr. Theodore Williams[31] regards high altitude climates as contra-indicated in anæmia, diseases of the heart and great vessels, chronic renal disease, and in all forms of albuminuria. This physiological study so far seems to support this clinical experience. In anæmia, perhaps, the ingestion of more fluid will prevent the fall of the blood-decimal. The ultimate rise in hæmoglobin value after a preliminary fall described by Wölff, Koeppe, von Jaruntowsky, and Schröder may represent the adjustment produced by the increased consumption of water prompted by the thirst which high altitude induces. It is easy to understand how cases of cardiac incompetency may be severely tried by the rarified and dry air of high altitudes, for the friction co-efficient of the blood will be increased by the polycythæmia and the deeper breathing will tend to maintain heart-hurry, and over-incitement of the weakened heart may be maintained by the increased respiration. But inasmuch as the breathing of rarified air seems to lead to filling of the arteries and reduction of the veins, it is quite conceivable that if applied *gradatim* in suitable cardiac cases it might prove to be of considerable therapeutic value. Physiology and pathology likewise join hands in regarding cases of chronic interstitial nephritis as unsuitable for treatment by the mountain cure, for in that disease polycythæmia and high arterial tension are prominent pathological conditions. Undoubtedly this physiological mode of treatment by mountain air is very decisive in character. It is certainly of the highest value in phthisis, and the profession will be ever grateful to two distinguished Fellows of this College for their successful advocacy of it—Dr. Hermann Weber, who brought forward its claims twenty-seven years ago, and who in his Croonian Lectures silenced the remnant of opposition to it, and Dr. Theodore Williams, who in his Lumleian Lectures adduced much valuable and telling testimony in its favour.[32]

VI. *Baths.*—Hot and cold baths, whether local (as hand baths) or general, produce contrary effects on the blood, the former lowering the percentage of the corpuscles and hæmoglobin and the latter raising them. The fall from a warm bath of fifteen minutes' duration may be 7 per cent., and the rise from a short immersion (three minutes) in cold water may be 4 per cent.[33] The alteration is merely a disturbance of the relation between the corpuscles and the plasma, for the blood-decimal remains unaffected. It would, therefore, seem that temperature, which is the predominant influence in bathing, alters the composition of the blood by retarding or accelerating the rapidity of fluid-transfer through the capillary wall, warmth slackening it and probably favouring the lodgment of tissue lymph and cold stimulating it. In all probability this influence is mainly exerted through the effect of warmth and cold on the intra-capillary pressure. These results confirm the observations of Winternitz and Kellogg[34] on the effect of warm and cold bathing on the blood. These observers refer the rise produced by cold bathing to general causes—increased activity of the heart and circulation, improved nerve tone, and the driving out of red corpuscles from the organs in which they had accumulated. The immediate effects of warm and cold bathing are, however, purely local.

VII. *Oxygen inhalation and ether anæsthesia.*—The inhalation of oxygen in rabbits produces, as a rule, a concurrent rise in the corpuscles and hæmoglobin. Probably this result

[29] Aero-therapeutics, by C. Theodore Williams, M.D. Oxon., p. 100.

[30] Probably the results of my observations at Davos Platz would have been still more pronounced had they been made in mid-winter, when the absolute moisture is much less than in May. I am indebted to the Cuverein of Davos for data showing that the average daily absolute moisture during the twenty-three days of observation was 5·03 mm. of Hg., whereas in the six months of last winter it was only 3·56.

[31] Op. cit.

[32] I must express my indebtedness to Mr. Waters, Dr. Buol, the Cuverein of Davos, and others, who greatly aided my inquiries at Davos.

[33] Bristowe and Copeman have shown by enumeration that in paroxysmal hæmoglobinuria the number of the chromocytes is reduced by exposure to cold air, or to a cold bath, or by plunging the hands in cold water. (Transactions of the Medical Society of London, vol. xii.) This interesting result is, however, one thing and the effect of cold immersion in healthy subjects is quite another, for it is highly probable that in hæmoglobinuria the normal resistance of the stroma is greatly reduced.

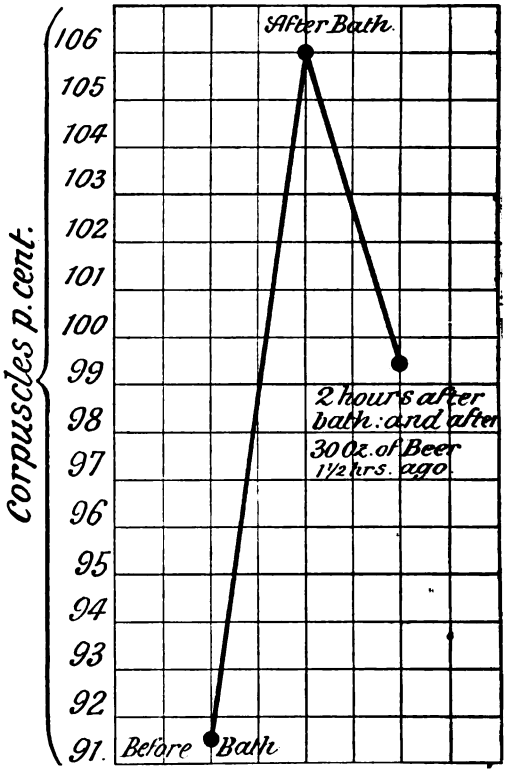
[34] Modern Medical and Bacteriological World (quoted by Dr. Leith, THE LANCET, March 28th, 1896).

Digitized by Google

arises from the increased arterial and consequent intra-capillary pressure caused by oxygen (see Lecture I.) It having been stated during the past year that ether anæsthesia, particularly in anæmic subjects, produces a rapid and marked diminution of the hæmoglobin,[35] it seemed desirable to make some observations on animals in order to ascertain if the normal red corpuscle is effected by ether, especially as observations on the effects of anæsthetics on the blood made before, during, and after operations are unreliable, because these themselves, whether producing loss of blood or not, profoundly disturb the composition of the blood. In a series of six experiments on rabbits, in which eighteen observations were made during the profound ether anæsthesia of one hour, the average blood-decimal was 1·01 before and 0·98 during the administration. The corpuscles examined during the anæsthesia were normal in appearance. No obvious after-effects were observed. From this too limited number of observations it would seem that ether anæsthesia does not produce a very pronounced effect on the normal red corpuscles. But it should not be inferred that it will be equally harmless when the corpuscle is abnormal, as in anæmia. There is some ground for believing that the stroma varies in its resistance to the same chemical agent; for example, it has been observed that the corpuscles of different subjects vanish at different rates when mixed with the same solution of sodium chloride in the same proportion and exposed to the same temperature. Lately I met with a good instance of this fact in two rabbits, one normal and the other spleenless; after mixing 5 mm. of the blood of each with 995 c.mm. of solution of sodæ sulph. the corpuscles of the spleenless animal were found to have vanished within two hours, while those of the normal rabbit remained intact for several hours longer.[36] So that it is quite conceivable that ether may be comparatively harmless to the normal red corpuscle and may yet be distinctly injurious to the abnormal one. The effects of chloroform on the red corpuscle have not been sufficiently observed to warrant any statement of results.

VIII. *On variations in the plasma and the circulation of water.* — The preceding observations have shown, on the one hand, that the hæmoglobin value of the corpuscles rises with rest and falls with systemic exercise and work; and, on the other hand, that the corpuscles are continually varying in their relation to the plasma. Though this latter fact has been already amply illustrated it will, I think, repay a little further examination. The concurrent variations in the percentages of the corpuscles and hæmoglobin, which have been so repeatedly pointed out, are indeed volumetric indications of the circulation of water into, or from, the blood—into it from the digestive tract and the tissues and from it by the kidneys, skin, and lungs, and probably into the muscles during exercise The blood is continually tending to balance its income and output of water and is thus always striving after a mean; but, notwithstanding this wonderful persistent adjustment, variations in the proportion of water present in the plasma are at the same time shown by these observations to be constantly taking place within certain physiological limits. It is true they are individually of comparatively short duration, but in this respect they resemble all the other oscillations of function which characterise health, such, for instance, as those described in the first lecture in connexion with the arteries. When, for example, the output of water, whether by the kidneys, skin, or bowels, temporarily exceeds the income, the volume of the plasma is for the time reduced and there is a proportionate rise in the corpuscles. Fig. 28 illustrates this temporary apoplasmia induced by a Turkish bath. All such transitory phases of concentration of the corpuscles can only be due to the shrinking of the plasma from loss of water.[37] But this question does not rest merely on examination of the blood derived from the finger. It has been conclusively proved by experiments on animals. Bizzozero, Golgi,[38] and others have observed that the intra-peritoneal injection of blood produces in from twenty to sixty minutes an enormous rise in the corpuscles, and Dr. William Hunter has shown that this result was merely due to concentration of the plasma (as shown by an equally pronounced rise of the specific gravity of the blood) caused by rapid effusion of serum into the peritoneum set up by the injection.[39] Professor Sherrington has likewise furnished equally conclusive evidence of the apoplasmic effect of operations and inflammations in animals. Inflammation was set up in a limb by immersing it in water at 52° C. for five minutes, and in the abdomen by applying to a knuckle of intestine sponges steeped in salt solution of the same temperature for five minutes. Taking the initial enumeration of the chromocytes

FIG. 28.



Percentages of corpuscles before and after a Turkish bath.

as 100, in the average results of all the experiments the maximum rise in the case of the abdomen amounted to 75 per cent. and in that of the limb to 35 per cent.[40] In some cases the duration of the apoplasmia was considerable, even five days. Sherrington and Copeman "have noticed that in the rabbit the operation of ligation of the vessels of the spleen and various other forms of experimental interference with the contents of the abdominal cavity, including even the simple opening of the cavity by an incision through the linea alba, are all followed by an increase in the specific gravity of the blood."[41] Such striking results as these suggest that some caution should be exercised in accepting any conclusions respecting the function of the spleen derived from observation of the blood during the first week after splenectomy. Clinical observation during last summer also indicated that persistent deviations are to be met with on one or the other side of the physiological mean percentage of the hæmocytes. For example, polycythæmia was frequently observed in chronic interstitial nephritis with high arterial tension, in diabetes mellitus, in chronic gout with increased arterial tension, and in those disposed to hæmorrhage (epistaxis, &c.).[42]

[35] The Blood Alterations in Ether Anæsthesia, by J. Chalmers Da Costa. Philadelphia Medical News, 1895, vol. i., p. 225.

[36] This bypath of the enquiry remains to be explored. In this observation there may be a hint as to the lowered resistance of the stroma in paroxysmal hæmoglobinuria.

[37] Apoplasmia (as indicated by polycythæmia) from abstinence from food and fluid has been recorded by Hayem, Reyne, and others. It is rapidly induced, for abstinence for twenty-four hours in man determines a rise in corpuscles from 4 to 500,000 per c.mm., and the augmentation is said to continue in the guinea-pig and dog until death.

[38] Centralblatt für dicinischen Wissenschaften, 1879, p. 917.

[39] Journal of Physiology, vol. xi.

[40] It has been pointed out that as a rule apoplasmia in man reduces "the worth." Out of the six protocols relating to these experimental inflammations of a limb and of the abdomen "the worth" fell decidedly in 4, slightly in 1, and was unchanged in 1.

[41] Proceedings of the Royal Society, vol. lv.

[42] At present I refer to this matter merely in general terms, for further observation is necessary to test these preliminary conclusions.

Lloyd Jones found that in arterio-sclerosis and in chronic interstitial nephritis the specific gravity of the blood was "highest in those in whom there is no œdema and in those who have cerebral hæmorrhage," and was "high in those who had had one attack of cerebral hæmorrhage and who are likely to have another."[43] Becquerel and Rodier (quoted by Lloyd Jones) found a high specific gravity and a great increase in the number of the corpuscles in twelve cases of cerebral hæmorrhage, and they add that the increase of the corpuscles "appear indeed to precede the cerebral hæmorrhage." In all such cases the persistent polycythæmia is, as a rule, associated with increased arterial tension and augmented elimination of water. It has been repeatedly observed that when the arterial tension is raised by any means, such as by small doses of suprarenal extract, by tonics generally, and even by mere change of air and scene and by recreation, the corpuscles will, as a rule, rise considerably; but it does not follow that the rise is necessarily and entirely due to the formation of chromocytes, for the major part of it probably arises from accelerated transfer of water from the blood as the result of increased intra-capillary pressure. Even in anæmia the blood may become apoplasmic. The pathogenic cause is not always obvious; it may, however, be frequently traced to a reduced ingestion of water and occasionally to the increased elimination of it probably under neurotic influence. In such cases the volume of the blood is obviously reduced, the percentage of the corpuscles is absolutely either normal or in excess, and that of the hæmoglobin—though it may be absolutely in excess—is always relatively subnormal, and improvement is indicated by a fall in the absolute percentages and a rise in the blood-decimal, as in the following example, in which the subject was a woman aged twenty-three:—

—	Date—1895.			
	Aug. 3rd.	Aug. 7th.	Aug. 19th.	Aug. 23rd.
Corpuscles	110	98	90	87
Hæmoglobin	105	96	91	96
Blood-decimal	0·954	0·98	1·01	1·09

In 1854 Becquerel and Rodier[44] described some cases of chlorosis in which the blood was not modified and was of higher specific gravity than normal; and Lloyd Jones alludes to similar cases—pale girls with a relative excess of corpuscles and a high specific gravity of blood.[45] On the other hand, the reduced elimination of water, as when the blood pressure is much diminished, tends to lower the percentages of the corpuscles and hæmoglobin. This fact is well illustrated by the recent very definite observations of Grawitz on the effects produced on the composition of the blood by loss of compensation and by the restoration of compensation. This observer shows that in the former condition the percentages of the corpuscles and of the dry residue of the blood and of the serum diminish, whereas when compensation is restored they again increase in proportion as the renal elimination of water is improved.[46]

In conclusion it is perhaps superfluous to point out that according to the data which have been advanced in these lectures it would seem that in health the composition of the blood varies quite as much as the calibre of the arteries, and that the variations in the former are largely influenced by the forces of the circulation; in a word, that the physiological relationship that subsists between the blood and the circulatory apparatus is as intimate as is the anatomical.

CORRIGENDA.—In Lecture III., on p. 1699, footnote 3, read *1896* for "1886"; on p. 1704, footnote 13, read *chlorid* for "chloras"; and in footnote 14, read *many* for "heavy."

CHICAGO EXHIBITION, 1893.—The medals and diplomas awarded to British exhibitors at Chicago have at length been issued to H. B. M. Ambassador at Washington, and have been transmitted by him to the Foreign Office. Sir Henry Trueman Wood has been requested by the Secretary of State to undertake the duty of distributing them, and this will be done at once, and all the exhibitors may expect to receive their medals within about a month from the present date.

The Ingleby Lectures

ON THE

MECHANISM OF BINOCULAR VISION AND THE CAUSES OF STRABISMUS.

Delivered at Mason College, Birmingham, on June 10th and 17th, 1896,

BY PRIESTLEY SMITH, M.R.C.S. ENG.,
OPHTHALMIC SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM; LECTURER IN OPHTHALMOLOGY AT MASON COLLEGE, BIRMINGHAM, ETC.

LECTURE II.[1]

GENTLEMEN,—It is an interesting experiment to show to an intelligent student a case of ordinary convergent strabismus in a child and to ask for his idea as to the probable cause of the squint. If he is in his anatomical period he will probably suggest that something is wrong with one of the muscles; if rather more advanced he will usually suppose that a nerve is paralysed; unless he has studied the matter specially he will hardly guess that it is the motor centres which are acting wrongly or that the cause of their doing so lies very probably in the eyes themselves. If he does understand this and has thoroughly grasped the teaching of Donders that convergent strabismus is commonly a result of hypermetropia, he will be apt to retaliate with another question he will want to know why this particular child squints while many others, equally hypermetropic, do not; and to this his teacher may possibly find himself unable to give a satisfactory answer. The possible causes of strabismus are very numerous, for, as you will remember, the turning of the eyes towards a particular point, seemingly such a simple matter, is in reality a highly complex act. It demands: (1) that the object be pictured with sufficient clearness in both eyes; (2) that the pictures be transmitted properly to the visual centres and that these latter instruct the motor centres as to the impulses required; (3) that the motor centres issue these impulses and that the nerves convey them to the muscles; (4) that the muscles respond normally; and (5) that the eyes be free to move. This is a chain of many links and a fault at any point may spoil the result—i.e., may lead to strabismus. In considering the several kinds of fault which may occur it will be convenient to begin at the other end and work backwards.

A. Mechanical displacement of the eye or limitation of its movement by a tumour or an effusion in the orbit, or by an adhesion with the eyelid, will cause deviation when certain movements are attempted. We need not discuss these cases, their nature is generally obvious.

B. A fault in one or more of the muscles will do the same. Congenital malformation or absence of a muscle has been found in a few instances, but the condition is probably uncommon; it cannot be diagnosed with certainty during life. Damage by injury, generally a perforating wound, is more often met with. Some years ago I saw a young man who, in vaulting over a table, had caught his eye on a gas bracket, tearing the conjunctiva and tearing out a large part of the internal rectus muscle; a divergent strabismus was the result. In another and more unusual case a boy was struck between the eyeball and the upper margin of the orbit by a blunt arrow. There was no wound, but for some weeks there was double vision of the kind which generally indicates lesion of the fourth nerve. Here, no doubt, the tendon of the superior oblique, or the pulley through which it glides, had been bruised and temporarily thrown out of action.

C. Lesions of the motor nerves by disease or injury constitute a much more important group. The lesion may lie within the skull, in the sphenoidal fissure, or in the orbit; it may be primary in the nerve itself, or secondary to changes in the surrounding parts. Much might be said of the etiology of these paralytic deviations, but this would carry me beyond my present limits. I will ask your attention rather to the special phenomena

[1] Lecture I. was published in THE LANCET of June 20th, 1896.

Digitized by Google

which they present and to the methods by which we investigate them. The salient point is this: the deviation increases or diminishes according to the direction in which the patient attempts to look; it manifests itself chiefly during those movements in which the services of the paralysed muscle are chiefly required. If, for example, the right sixth nerve be injured the right external rectus will be partially or completely paralysed. When the patient desires to look to the right the conjugate centre which governs that movement (see Fig. 7, R, Lecture I.) will issue the customary bilateral impulse; this will be conveyed properly to the left eye, but will be weakened or arrested in its transit to the right. The left eye, therefore, will make the normal movement, while the right will remain still or will "lag behind" its fellow. On the other hand, when the patient desires to look to the left the services of the damaged nerve are not required, the bilateral impulse is carried normally to the two eyes, and they move in harmony. Observe, however, that the deviation does not always begin and end at the median line; the loss of tonicity in the paralysed muscle gives its antagonist a preponderance and the eye is drawn somewhat to one side even when the fellow eye is directed straight forwards. On the other hand, when the paralysis is slight the deviation may manifest itself only when the patient tries to look much towards the affected side. The difference in the movement of the two eyes in paralytic strabismus may be expressed by a diagram. Here is a case of paralysis of the right external rectus (Fig. 11).

FIG. 11.

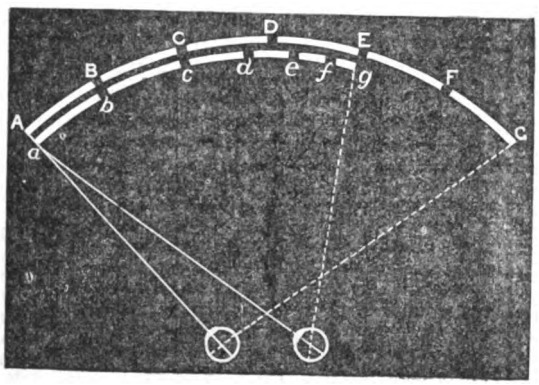

Diagram showing unequal movements of the two eyes in paralysis of the right external rectus.

The arc A G represents the excursion in the horizontal plane which the two eyes ought to make in harmony; *a g* is the excursion which the right eye actually makes while the left travels from A to G. For a certain distance—namely, from A to C—the two eyes move harmoniously; then the paralysed eye begins to lag behind; it reaches only to *d* when it ought to reach to D; to *e* when it ought to reach to E. The distances *d* D, *e* E, and so on, represent the amount of its deviation at each part of the journey. In examining such cases it is necessary to remember that the deviating eye is not always the paralysed eye. If the paralysed eye happen to have much better vision than its fellow the patient will strive to make it follow the object in spite of the paralysis; the strong impulse will be sent equally to the non-paralysed eye and will cause this to deviate, not to lag behind but to shoot ahead of the paralysed eye, and the deviation will be greater than in the former case. For example (Fig. 11), the strongest effort of which the conjugate centre is capable will enable the paralysed eye to follow the object to the point *g*, and will simultaneously carry the non-paralysed eye to the point G; the deviation is now *g* G. If the patient had followed the object with the non-paralysed eye to the same point, say E, the paralysed eye would have lagged behind at *e*; the deviation would then have been only *e* E. In many cases of paralytic deviation the lagging of the eye is too slight to be easily seen; in any case, mere inspection is a very uncertain method of testing it; fortunately we have a better. The double vision which is commonly present affords a precise test. The deviating eye sees the object in a false position—it sees a false image; the position of the false image will tell us the direction and the amount of the deviation if we bear in mind that the false image and the cornea deviate equally and in opposite directions. We judge of the position of an object from the positions of its pictures on the retinæ, and when either retina is displaced without our knowledge, i e., otherwise than by an effort of the will, our judgment is by so much led astray. For example, when the cornea is displaced inwards the picture which should fall on the macula is displaced to a part of the retina which corresponds, when the eye is straight, to an object situated outwards; the patient judges as though the eye were still straight (see Fig. 10, Lecture I.), and therefore sees the object displaced outwards. Hence in double vision the positions of the two images will tell us the positions of the two eyes, provided we know which image belongs to which eye. This is readily determined. Using a strip of white paper as the object to be looked at, we place a disc of red glass before one eye; the patient now sees one white image and one red, and the red image belongs of course to the "red eye." Moreover, the varying distance between the two images as the eyes move will tell us in which direction the deviation increases, in which it diminishes or disappears. Diplopia, therefore, is a very delicate index of deviation. Here is a working formula which applies to all cases, to mechanical displacement as well as to paralytic deviation:—1. Ascertain in which direction the images stand furthest apart: the inefficient muscle is one of those which normally turn the eyes in this direction. 2. Ascertain which image belongs to which eye: the inefficient muscle belongs to the eye whose image stands furthest in the said direction.

This formula saves both time and mental effort in the press of practical work, but it must be confessed that there are a good many cases, especially where the lesion is complex or where it is old and has led to secondary changes in the muscles, in which the most careful examination will leave us in doubt. I must remind you also that these paralytic deviations are not always accompanied by double vision, for one eye may have little or no sight, or the patient may have learned to disregard or suppress the impression which it receives. Lastly, it must be remembered that there is such a thing as double vision with a single eye, usually from defects in the refracting media, possibly in some cases from psychical disturbance. We must not assume that a patient who sees double has a deviation of the eye until we have made certain that one image belongs to one eye and the other to the other. The other disturbances which paralytic deviations often cause I can merely mention in passing: they are giddiness due to seeing objects in a false position, an altered carriage of the head, whereby the patient contrives to minimise the demands made on the paralysed muscle, and closure of one eye, by which he avoids the double vision altogether.

D. Lesions of the motor centres, unless confined to the primary nuclei of the nerves, cause paralytic deviations of bilateral type. The loss of movement is common to the two eyes. Conjugate deviation of both eyes to the right or left is the best known form; it is frequently associated with hemiplegia, the same lesion causing both. When the lesion is in the cerebrum the limbs of the opposite side are paralysed and the eyes cannot be turned towards the paralysed side; they are drawn over towards the other side by the unopposed action of the other conjugate centre. When the lesion is in the cerebellum the limbs of the same side are paralysed and the eyes are unable, as in the former case, to look towards the paralysed side. When it is in the pons the eyes are turned towards the paralysed side. Another form of bilateral deviation due to central lesion is paralysis of convergence. There is a constant divergence of the eyes which the patient cannot diminish, yet the internal as well as the external recti remain active for conjugate movements to either side. Paralysis of convergence is apt to be associated with loss of accommodation, of contraction of the pupils, and of downward movement, for the several impulses which produce these movements arise from closely adjacent parts of the brain. Paralysis of divergence is the counterpart of this and is apt to be combined with loss of upward movement. In cases of this class, you will observe, certain muscles are at one moment powerless and at another active, according to the nature of the movement attempted.

E. Faulty control of the motor centres.—The great majority of all the cases of strabismus which we meet with, especially of those arising in early life, depend, not on faults or lesions in the motor apparatus itself, but on extraneous causes which impair its action. The commonest forms are frequently associated with errors of refraction, convergent strabismus

Digitized by Google

with hypermetropia, divergent with myopia. Before discussing other causes let us consider the influence of these conditions. When we look from a distant to a near point our eyes undergo three changes: the ciliary muscles contract so as to accommodate each eye for the near point, the pupils contract, and the internal recti contract so as to converge the eyes for the point in question. These three changes are always wanted simultaneously, and the centres which govern them are therefore placed close together in the brain, so that they may act, as it were, by a common impulse, and the centres on the two sides are closely united, so that the impulses may be strictly bilateral—i.e., issued with equal force to the two eyes. The habit of using these impulses together makes it difficult to use them separately; thus it is difficult to accommodate without converging or to converge without accommodation. This is easily demonstrated. While looking at a point, say, at three feet distance I place concave glasses before my eyes. Now, if I am still to see the object clearly I must accommodate more strongly than before in order to neutralise the effect of the glasses, but I must not converge more or I shall see the object double. This is difficult and would soon become painful, for I have to resist a strong tendency to increase my convergence. If I cover one eye with the hand so as to exclude it from the act of binocular vision it at once squints inwards—a proof that it was previously kept straight with difficulty. On the other hand, if while looking at a near point, say at twelve inches, I place convex glasses before my eyes I must relax my accommodation without altering the convergence, which, again, is difficult, if not impossible. These difficulties, here induced artificially by means of glasses, are naturally present, more or less, in hypermetropia and myopia. As compared with the emmetrope, or normal-sighted person, the hypermetrope is obliged to make an extra effort of accommodation; he therefore tends to converge too much—to squint inwards. The myope, on the other hand, for near objects, must accommodate less than the emmetrope, and therefore tends to converge too little—to squint outwards. The squinter, of course, does not allow both eyes to deviate either inwards or outwards, but turns both to the right or to the left by means of one of the conjugate centres, so as to correct the deviation of the one and double that of the other. The squinting eye, therefore, owes one-half of its displacement to the excess or deficiency of convergence, the other half to the conjugate movement which keeps the fellow eye straight. The fundamental ideas in this explanation of strabismus we owe to Donders. He taught us the relationship of accommodation to convergence, the nature of hypermetropia, and its connexion with convergent strabismus, and in doing this he raised a whole department of ophthalmology to a high scientific level, and conferred immense benefit on the legions of hypermetropes, who are always with us. Since his great work appeared convergent strabismus has been cured in many cases every year by the use of glasses, and this fact is a sufficient reply to those writers, few in number, who still deny the essential truth of his teaching. Still, that teaching does not cover the whole ground. Some squinters have no hypermetropia; many hypermetropes have no squint, and no tendency to squint even when one eye is covered. In hypermetropia normal convergence is the rule and squint the exception. We have then to ask, How does the average hypermetrope manage to combine an extra effort of accommodation with a normal effort of convergence, whereas you and I, trying the experiment with glasses, find it impossible to do so? The average hypermetrope learns from the cradle upwards to regulate his eye-impulses according to the special requirements of his eyes. He trains his motor centres to a different partnership from that which is present in the emmetrope. He teaches the convergent centre to act moderately while the accommodative centre acts strongly. Now, this education, this purposive control of coördinated movements, depends on the higher cortical centres. We may say, therefore, that when hypermetropia leads to strabismus the control centres have failed in their duty.

Conditions which impair the control of the eyes.—Anything which spoils the retinal picture in either eye renders the blending of the two pictures comparatively valueless and is likely to lead to strabismus. Even in the adult who for half a lifetime has used the two eyes together a loss of vision in either eye may cause it to deviate. He no longer takes the trouble to maintain a particular degree of convergence, but allows the useless eye to assume the position which involves least effort. It may remain properly directed, or it may deviate in a purposeless fashion inwards, outwards, or in any other direction, according to its anatomical connexions and the various nerve impulses which still act upon it.[2] The young child under similar circumstances has a still greater tendency to squint, for his eyes have had but little training in harmonious action. Thus, corneal opacities following purulent ophthalmia or phlyctenular ulcer, opacities in the deeper media and disorders of the retina, choroid, and optic nerve are frequent causes of strabismus in early life. We cannot always exclude such causes, even though we fail to discover them a few years later. The hæmorrhages in the vitreous or retina which are sometimes present in the new-born child after long and difficult labour, the changes in the retina or optic nerve which occur during whooping-cough and other acute disorders, even the occlusion of one eye with a bandage during the early months of life, may probably sometimes suffice to check the development of the visual apparatus during its period of most rapid growth and thus to lead to strabismus. Such cases when examined some years later might show no obvious defect in the squinting eye. Again, a great difference in the refraction of the two eyes, especially a high degree of astigmatism in one, will prevent the fusion of the two retinal pictures. The controlling influence may be suspended in other ways than through the absence of good retinal pictures. The mother will often tell us that her child's squint began after a fright, after a fall, during a fever, or at the time of teething; not very seldom there are worms in the intestine; we frequently see that the squint comes on when the child is startled, poorly, or nervous, and disappears or nearly so when he is in vigorous condition; in some cases the inability to exercise the necessary control is distinctly hereditary. Since Donders threw a new light on the causation of strabismus, we have been apt, I think, to treat such points as these with scant attention, especially when we find a few dioptres of hypermetropia in the eyes; but in all conditions of this kind the higher brain powers are more or less disturbed, and just as the hand is apt to become unsteady or the tongue to stammer when its owner is "nervous," so under similar circumstances the eyes are likely to escape from the necessary control. Let me give you a single example of the production of strabismus by fright. A girl who up to eight years of age was healthy and free from eye-trouble was shut up for punishment in a dark room by a well-meaning but misguided relative. The child was utterly terrified and climbed out of her prison through a small window at risk of life and limb. From that time she seemed changed in character, became liable to faint, and had frequent strabismus. To summarise the matter: in infancy the control of the cerebral coördinations is less complete and less stable than in later years, hence the child is more liable than the man to lose it under trivial or temporary difficulties, either ocular or cerebral. In presence of hypermetropia an extra effort of control is needed, hence the hypermetropic child is more liable than others to acquire strabismus. With his first lapse into strabismus the child enters on a vicious circle in which cause and effect are apt to perpetuate each other. He quickly learns to disregard the picture belonging to the deviating eye, and having done so makes no further effort to combine it with that of the fellow eye. The loss of binocular vision then confirms the squint. If it become habitual before the child's visual perceptions are fully developed he is likely to be amblyopic in the squinting eye throughout life. Thus amblyopia is often a consequence as well as a cause of squint. Secondary changes in the muscles and other tissues around the deviating eye occur in course of time and confirm the displacement which originally caused them.

Myopia as a cause of strabismus is not quite the counterpart of hypermetropia, for high myopia is rarely present in the young child. In early life the future myope learns the ordinary association of convergence with accommodation; later, as his myopia develops, he gradually unlearns it and learns to converge without accommodating, but he rarely unlearns completely. The majority of myopes show some outward deviation when one eye is covered, and in a few cases of high myopia this leads to actual divergent strabismus, especially when vision in one eye becomes defective. On the other hand, a few highly myopic persons do succeed in keeping the divergent impulse entirely in abeyance, and, indeed, acquire the habit of persistent convergence for short distances: it is only at short distances that they see well,

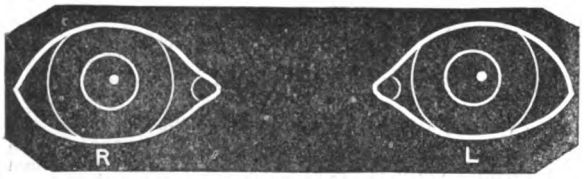
[2] See Hansen Grut's Bowman Lecture. Transactions of the Ophthalmological Society of the United Kingdom, 1890, p. 1.

Digitized by Google

and they make noeffort to obtain binocular vision of distant objects, hence the apparent paradox that concave glasses tend to correct convergent strabismus in such persons. The exceptional occurrence of high myopia in infancy would seem to predispose to convergent strabismus, for the child who never sees distant objects properly is likely to take no trouble to acquire binocular vision except for short distances. Other auxiliary causes and various atypical forms of strabismus might be mentioned, but time forbids. I will conclude by dealing very briefly with a few of the practical questions which often arise in connexion with the common strabismus of childhood.

Does the child squint?—The family is divided in opinion; the medical man is asked to decide. We cannot test a very young child, as we should an older patient, by covering each eye separately while he looks steadily at a distant object, but we may do it with the ophthalmoscope, for a child aged two years or less will look readily at the bright mirror if care is taken not to startle him. The observer standing about

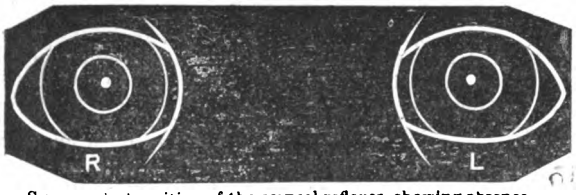
FIG 12.



Asymmetrical position of the corneal reflexes, showing inward deviation of the left eye.

two feet away throws the light first on one eye, then on the other, and notes the position of the corneal reflex in each—i.e., the minute bright reflection of the mirror, which in normal eyes is usually seen just to the inner side of the centre of the pupil. If the corneal reflexes are symmetrically placed in the two eyes there is no strabismus, at least at that moment; asymmetry, on the other hand, shows deviation of one eye and tells us its direction (Fig. 12). A false appearance of strabismus in a young child is usually due to the condition known as epicanthus, a redundant fold of skin hiding the inner angle of the eye (Fig. 13). A squint which

FIG. 13.



Symmetrical position of the corneal reflexes, showing absence of deviation in a case of epicanthus simulating convergent strabismus.

is latent will usually manifest itself when one eye is covered, especially if the child be caused to look at an object placed six or eight inches from his eyes.

At what age should a squint be treated?—The child should be examined with regard to the cause of the squint as early as possible. Before discussing treatment we want to know (1) whether the squint is paralytic or concomitant, in other words, whether the two eyes move unequally or equally when the child looks in different directions; (2) whether the squinting eye is able or unable to "fix" the object when the fellow eye is covered; (3) whether it presents in its own structure any visible cause of defective vision, such as opacity of the media or disease of the fundus; (4) whether the onset of the squint was connected with any obvious disturbance of the nervous system; (5) whether it is always in the same eye or alternates between the two; and (6) lastly, in every case we want to know the refraction of both eyes—this, with the help of atropine and the shadow-test, can be determined even in the youngest child—and, if the child be old enough, the acuteness of vision in each eye when the refractive error is corrected. These data being obtained so far as may be possible we are in a position to speak of treatment and the future probabilities.

Will glasses cure the squint?—If there be a considerable hypermetropia in the straight eye glasses will probably diminish the deviation, whatever be the condition of the deviating eye; but if this latter fail to right itself when the fellow eye is covered they will not effect a real cure. The more promising cases are those in which the squint alternates between the two eyes, the most promising being those in which it appears and disappears periodically; in a case of this kind, if we find that atropine banishes it entirely for the time being we may be almost sure that glasses will remove it permanently. But the glasses must be correct, neutralising astigmatism as well as hypermetropia in both eyes. They must "fit," so that the child looks through them and not over them, and they must be worn constantly from morning till night. Failure frequently depends on lack of perseverance. The parents want a speedy cure and, not getting it, they allow the child to lay aside the glasses after a few weeks or months or fail to renew them when he breaks them. Sometimes they complain illogically that "the glasses do no good, for the squint returns the moment they are taken off." In reality this is the strongest proof of their value. But we must not expect too much from glasses; they can lessen the excess of convergence and they can sharpen the retinal pictures, but they cannot create the visual perceptions and motor impulses which are essential to the acquirement of binocular vision.

What else can be done?—The squinting eye, or rather the perceptions and impulses which ought to control its movements, can, to some extent at least, be educated. The process will be difficult or impossible, according to the duration of the previous neglect. The patient must be taught first to perceive the impressions belonging to the squinting eye; then to perceive them simultaneously with those of the fellow eye—i.e., to see double; next to make the effort which is necessary to unite the double images; and, lastly, to form those judgments of distance and perspective which perfect binocular vision gives. Cures, absolutely complete in this last respect, as proved by Hering's drop test (see Fig. 9, Lecture I.), are rare but not unknown. For this process of teaching several means are at our disposal. We may cause the patient to use the squinting eye exclusively by covering the other; we may induce him to give it the preference when both are open by partially disabling the other with atropine; we may teach him to notice both pictures simultaneously and ultimately to blend them by means of persistent practice with the stereoscope,[3] differentiating them at first by different coloured glasses and approximating them by prisms; and we may facilitate the process at any stage by bringing the eye into better position by means of tenotomy.

When is it best to operate?—No operation should be done until the nature of the squint has been thoroughly investigated and until efforts have been made to minimise the deviation and to sharpen the visual perceptions by glasses and by regulated practice. When these measures are inapplicable or have ceased to give progressive benefit operation is in place and is hardly contra-indicated by age in either direction. But the younger the child the more important it is to do too little rather than too much. Full correction of a squint by tenotomy in very early life may give over-correction later. Partial correction by the first tenotomy, then an interval with regulated exercise, and then a similar tenotomy on the fellow eye in case of need are better practice. Confirmed strabismus often diminishes in degree as time goes on, hence the too common idea that time alone will often cure a squint, and the advice, not seldom given, to "wait and see." For the squinting eye this too often means waiting and not seeing. Time alone may lessen the disfigurement, but will not remove the disability. Binocular vision is not recovered in this way.

[3] See Javal on Binocular Vision in relation to Strabismus. Abstract in Ophthalmic Review, vol. xi., 1892, p. 288.

THE LEICESTER BACTERIOLOGICAL INSTITUTE.—During the Royal Agricultural Show at Leicester, at Stand No. 431, the Leicester Bacteriological Institute have given to agriculturists and dairy farmers demonstrations by means of microscopes of the various pathogenic organisms common to animal and man—tubercle, anthrax, tetanus, erysipelas, actinomycosis, swine fever, typhoid fever, pleuro-pneumonia, diphtheria, &c., and also exhibited cultivations on various media of the different micro-organisms; photographs of the different micro-organisms and their mode of growth; sections of organs containing bacilli; micro-organisms in food—meat, milk, and water; drawings; pamphlets of explanation; exhibition of the antitoxic serums, including antitoxins for diphtheria, tetanus, erysipelas, rabies, typhoid fever, &c.; tuberculin and mallein and their mode of use.

THE PRACTICAL APPLICATION OF "X" RAYS TO SURGERY AND SURGICAL TEACHING.

BY WILLIAM TURNER, M.B., B.S. LOND., F.R.C.S., ENG.,
SURGICAL REGISTRAR TO KING'S COLLEGE HOSPITAL AND SURGEON TO THE SEAMEN'S HOSPITAL, ATTACHED TO THE BRANCH HOSPITAL.

(Continued from p. 1717.)

2. To General Bone Surgery.

ITS application to general bone surgery, I wish first to say, is not chiefly from the diagnostician's point of view. I have not photographed a single case where the diagnosis was materially altered by the process, but in confirming a diagnosis and in finding out the exact extent of an injury it is of greater value. First in importance comes the photographing of fractures to ascertain the extent of the injury especially, the amount of comminution and splitting longitudinally of a bone being necessarily almost impossible to determine unless post mortem. A skiagraph was taken in the ward, the patient not being disturbed and the splint and dressings being untouched; his leg also had extension applied which was not removed. I might mention here that the noise caused by the induction coil, sparking, and contact breaker is not sufficient to materially disturb patients, and on occasions when I have had to use it at night most of the other patients slept on through it. In this case the exposure given was seven minutes. The notes of the case are as follows.

A man aged forty-four years was admitted into King's College Hospital, having fallen from a ladder into the pit of a theatre. He was found to have a compound comminuted fracture of the tibia and fibula and a simple fracture of the femur on the same side. The lower fractures were explored, some loose portions of bone removed, and a wire placed round the tibia. The photograph taken on May 11th, five weeks after the accident, shows longitudinal splitting of both bones with a large amount of comminution and also that the early callus is very transparent to these rays and so does not show. The skiagraph of the femur with eight and a half minutes' exposure shows an unusual condition of impaction of the shaft of the bone at the junction of its upper and middle thirds, the upper part being split into two pieces, enclosing the conical-shaped upper end of the lower fragment. This condition could not have been diagnosed without this method, and helps in the prognosis of the case, especially as regards the probable shortening.

Again, the process can be used to photograph through water-glass, enabling the surgeon to watch the progress of a case treated by this method; thus Fig. 3 is taken with a six and a half minutes' exposure, which is longer than it ought to have been owing to the patient having a bad cough, it being necessary to stop the instrument for at least one and a half minutes owing to two or three attacks of coughing; the patient kept his arm fairly still during the attacks and it came back to the original position. The man in question was forty-four years old; he met with an accident in July, 1894, and broke his right radius. In June, 1895, the fracture being still ununited, a piece was taken out of the ulna and both were wired, as seen in the illustration, showing that there is still no osseous union between the bones. The other applications of the process are also numerous, as, for instance, in injuries about the elbow-joint, which are often obscure; many of them can be fully comprehended by means of the cryptoscope or from the skiagraphs. Also in deformities it may be found useful; for instance, in finding the exact position of an abnormal curve of a femur or the absence or presence of a metatarsal or metacarpal bone with congenital deformities of hands or feet.

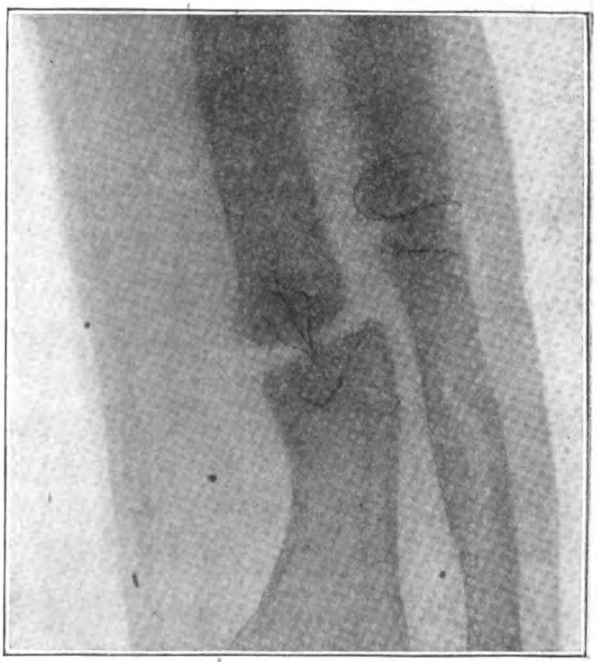
It would be profitable to ascertain the value, if any, of his work in tuberculous and malignant disease of bones or joints; at present I am not in a position to give any definite opinion on these subjects. I am sure that two important items for all this class of work are (1) the short exposures, which, though necessarily often not producing very dense negatives, nevertheless show the surgeon what he wants to know, and (2) the use at the bedside so as not to move or disturb the patient. I may add that I am at present in favour, for clinical purposes, of skiagraphs in preference to the cryptoscope. I next give a few examples of this work as applied to teaching purposes.

3. Application to Teaching Purposes.

I now come to the part of this subject that at present seems to have been kept more or less in the background, but which, I think, will be a very important addition to the medical schools—namely the application of skiagraphy to teaching—and I will endeavour to give a few examples where this process may materially assist the teacher in his often difficult task, and the student in his endeavours to grasp the "whys and wherefores."

A. Osteology.—Firstly the process can be applied to the study of osteology—e.g., the method of growth of bones with the epiphyses, their positions, their appearance at different ages, and, lastly, their date of union to the diaphysis. For instance, in a skiagraph of the hand and wrist the epiphyses of the phalanges and metacarpals are easily demonstrated and one glance shows clearly to the student their position and difference between the metacarpal of the thumb and those of the fingers; also the date of appearance of the epiphysis of the lower end of the radius is shown—I should say the

FIG. 3.



Reproduction of photograph of fractured radius and ulna showing no union and wires which had been put in. Exposure six and a half minutes.

commencement of ossification rather than the appearance of the epiphysis, as mere cartilage is not opaque to these rays and only leaves a space on the plate, whereas when ossification has commenced, a shadow is thrown on the negative This is well shown in two skiagraphs: one is of a boy aged four and a half years, where the epiphysis is seen only as a space, whilst in the other, taken at the age of five and a half years, it is seen as a definite opacity. Similarly the method of union of the epiphyses of the upper end of the humerus can be determined and demonstrated. In a skiagraph of a knee of a boy aged twelve years taken antero-posteriorly with an exposure of six minutes, the epiphyses round the joint are very obvious. These points of course to many appear easy enough to understand, but the student commencing his studies will grasp facts much more readily with a skiagraph before him than by means of post-mortem specimens (which so often get damaged) or diagrams.

B. Surgery.—Now, with regard to surgical teaching there are very many points of interest. The above-mentioned skiagraph of the knee-joint enables the teacher to point out to the student the importance of remembering the position

Digitized by Google

of these epiphyses and the line of cartilage from which the bones grow when the operation of excision of the knee is about to be performed, and to emphasise the supreme importance of not injuring the cartilage, as if it is damaged more shortening must occur, and this point is one which is made of importance at examinations. The skiagraphs of the two wrists of a patient taken in the dorso-palmar position with an exposure of four minutes, illustrations of which are reproduced (Figs. 4 and 5), and the fellows of them taken in the radio-ulnar position with six minutes' exposure, demonstrate to the student: (*a*) the position of a Colles' fracture; (*b*) the clinical evidences of it; and (*c*) the causation of the deformity. Thus is rendered clear the position of the corresponding styloid processes—the prominence on the dorsal surface being produced by the backward and upward displacement of the lower fragment, whereas that on the palmar surface is due to the lower end of the upper fragment; the rotation of the lower fragment on its antero-posterior axis and consequent abduction of the

FIG. 4.

Skiagraph of a Colles' fracture. The line of fracture appears across the lower end of the radius.

hand and prominence of the styloid process of the ulna; and the rotation of the lower fragment on its transverse axis with resulting extension of the hand at the wrist-joint. These point out well the use of taking skiagraphs of the normal as well as the abnormal side for comparison. In many cases, and especially for permanent records or for teaching purposes when the cases themselves are not available to be shown to the student, great assistance could be got by comparing the ordinary photograph with the skiagraph, thus pointing out the effect seen in the former with the cause as shown in the latter. Again, in cases of difficult physical signs—as, for instance, a bad comminuted fracture of the head of the tibia where, except to the experienced eye and hand of the surgeon, the question of injury to the lower end of the femur is not easily excluded—the student may be greatly assisted by the skiagraph, and thus be enabled to grasp the meaning of the clinical evidences presented by the patient, which, without it, appeared uncertain and indefinite. Another and last instance is that afforded by the examination of joints after an operation has been performed upon them, especially hips and elbows after excision. Here there is often much difficulty in explaining the final condition of the joints, and the skiagraphs will greatly aid the teacher and the student. I have before me two skiagraphs of the hip-joints of a boy aged fifteen years, taken when the patient was in bed in the ward as described before with exposure of ten minutes, the one is normal, showing the epiphyses of the head and great trochanter; and the other one is after excision had been performed for tuberculous disease; here the upward and backward displacement of the rest of the femur and the absence of the head and neck are easily shown to the student. Likewise, with an elbow after excision for similar disease and the resulting almost perfect movement, the resulting false joint is easily compared with a normal one and shown.

I wish to add one point, although it has no direct bearing upon the previous points I have tried to draw attention to, and that is, that people who have a tendency towards bringing

FIG. 5.

A normal wrist-joint, for comparison with Fig. 4.

actions against medical men for unskilful treatment will be tempted to use this method as evidence in their favour. But fortunately this may show the opposite; as in more than one case of mine the trouble has either been shown to be due to something else altogether or to adhesions remaining in the joint after the injury.

I wish to express my great indebtedness to Mr. W. H. Sodeau, B. Sc. Lond., for his valuable assistance, and for many practical suggestions which he has made from the time I commenced to experiment, and to Mr. Herbert Jackson, of King's College, for having not only given me much advice but for lending me some tubes to start my work without which I should not have been able to begin until much later; and also I have to thank Mr. W. Watson Cheyne for having allowed me to publish so many of his cases. I have also to thank the staff at King's College for their help, and especially Mr. William Rose for letting me use his case of Colles' fracture in the way I have above.

SHOULD A HEALTHY MOTHER SUCKLE HER CONGENITALLY SYPHILITIC CHILD?

BY GEORGE OGILVIE, B.SC., M.B. EDIN., M.R.C.P.LOND.,
PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S-PARK.

IT is a matter of much gratification to me to find myself on nearly all points in accordance with the views expressed by Dr. Coutts in his Hunterian lectures on Infantile Syphilis. Everyone, indeed, must be indebted to him for having put an end to a good deal of dogmatic teaching, by subjecting those points about which there is, or has been, controversy to sound criticism based upon a careful and minute study of facts, and his lectures mark a step forward in our knowledge of the subject. Dr. Coutts considers the question whether there are exceptions to Colles' law as settled in the affirmative, but he does not think that "such eminently infrequent occurrences ought to largely modify our practice in allowing apparently healthy mothers to suckle tainted infants," and he adds: "Following in the same path as Henoch, the only limitations I would place on suckling by mother or wet nurse would be the presence of excoriations on her nipple and that of ulceration or fissures about the mouth of the infected infant." With reference to this, it appears to me that it is neither safe nor proper to adopt such a rule of practice.

That the infection of a wet nurse by a tainted child, whether the nurse be or be not its mother, is a possibility has been established. Dr. Coutts shows from the statistics of the Shadwell Hospital that the frequency of the occurrence of the infection of wet nurses has probably been much exaggerated, but still the thing occurs, and it has to be accepted as a fact that a healthy woman, whether she be the child's mother or not, may contract syphilis by suckling a congenitally syphilitic child. The position which I venture to take up is that it is not right to expose a woman to that risk, even though Henoch's precautions are taken. Of course, if the tainted child's mother enjoys a certain amount of immunity which is not enjoyed by a wet nurse who is not its mother, it would be safer for the mother to suckle the child than for such unrelated wet nurse, but infection may come to either, and the question is whether Henoch's precautions give such a security as to justify our running the risk. In my opinion they do not give such a security. It does not seem to me that it would be sufficient to examine the nurse's nipple and the child's mouth before allowing the child to suck. The nipple and mouth would require to be kept under observation, and Henoch's rule does not say how the practitioner is to act in the event of lesions of the nipple or mouth appearing during the suckling, say weeks or months after it has commenced. But in addition to this, the lesion of the mouth or nipple may be so small as to escape detection and yet be sufficient to allow of infection. It therefore appears to me that the rule for the practitioner ought to be to prevent the risks to a healthy wet nurse from suckling a congenitally syphilitic child, by not giving his sanction to such suckling. I have elsewhere pointed out that under very exceptional circumstances a particular case may offer itself, in which deviation from this rule is perhaps justifiable, but, in my opinion, no fault can be found to that practice which never makes an exception and never allows a healthy woman to suckle a tainted child. Since the law of Colles is proved to have exceptions, this prohibition should apply to nurses who are mothers as well as to other nurses; indeed, the practical dealing with mothers should be the same as that in regard to hired wet nurses if protection is to be always secured. It may of course be said that it will be injurious to syphilitic children as to children generally, not to derive their nourishment from woman's milk—that of mothers or of other women—and I cannot say that this may not be true. But in this conflict of interests, I believe that few will think of deciding in favour of the child. There may be some disadvantage to the child from artificial feeding, but this may be easily overrated. In some of the large Russian institutions a large number of children suffering from congenital syphilis have quite recently been brought up entirely on the bottle with completely satisfactory results. I do not desire the extermination of the tainted or weakly, but it seems to me that I am right in regarding the health and life of the mother of a tainted child, or of its hired wet-nurse, as of higher value than the health and life of the child itself. Most of us perhaps go as far as Fournier does when he says: "For an infant born of a syphilitic father and mother there are but three alternatives: (1) Either it dies before birth, and that is undoubtedly the best thing that can happen to it; (2) or it will be born at the full time the subject of syphilis; (3) or it will survive with compromised health and exposed to all *les alternatives de la maladie*." I have a difficulty, in short, in regarding it as warrantable to expose a healthy mother or a healthy hired wet-nurse—perhaps destined to have other children—to the least risk of sustaining a serious injury, on the chance of bettering a life already seriously damaged. It will be seen from what I have written that I go further than Dr. Coutts, and cannot accept Henoch's precautions as sufficient not only as regards hired wet-nurses, but also as regards mothers, since Colles' law has been shown to have exceptions, though we do not yet know much as to the frequency or infrequency of such exceptions. In other words, I desire to take a safe course in the interests both of maternal and non-maternal wet-nurses.

Mr. Hutchinson does not appear to regard the precaution, which is recommended by Henoch and adopted by Dr. Coutts as necessary; at least, so far as I know, he does not indicate that he takes the precaution, and with his views it is scarcely seen that he would have any sufficient reason for doing so. He has "expected" the occurrence of exceptions to the law of Colles, and, indeed, admits that they have occurred, but he does not think we should "allow these extremely few exceptional cases to interfere with our general rule of permitting mothers (of tainted children) to nurse their infants."[1]

Before the discussion in January last at the Royal Medical and Chirurgical Society, I was not aware that Mr. Hutchinson did admit the actual occurrence of any exceptions. Indeed, he had previously expressed himself often and strongly in the opposite sense, as, for instance, when he says: "I am not aware that a single exception has been recorded;"[2] and again, "if there is on record a single case in which the mother of a syphilitic infant is proved to have contracted a chancre from her own child it has escaped my reading."[3] and again at a later date, "since Colles' day no exceptions to his law have I think been put on record which are worthy of trust."[4] But Mr. Hutchinson though he has never seen an exception, now admits the occurrence of exceptions, and says that it is reasonable to expect them. Notwithstanding this, however, he is of opinion that we "may continue" to "encourage mothers of syphilitic children to nurse the children themselves, not giving them, indeed, an assurance of positive immunity but telling them that for all practical purposes they are safe."[5] His reason—his only reason, so far as I know—is that it would be a pity if, by not allowing mothers to suckle such children, we condemned the children, "to the additional risk of life entailed by their not being nursed by the mother."[6] I am not able to see that this is a proper and justifiable practice. In my opinion Mr. Hutchinson exaggerates the risk to the child. For infinitely weaker causes than their possible protection from syphilis mothers are often allowed and advised to bring up their children by hand, and without a thought that this involves any important risk to the life of the children. Whenever it is shown that Colles' law is not a law which has no exceptions—and this I believe to have been clearly shown—it seems to me that no mother should be exposed to the risk of contracting a chancre by nursing her syphilitic child.

The rule as regards mothers should in my opinion be exactly the same as that regarding unrelated wet nurses. The first are probably in less danger than the last, but they have been now shown to be in some danger, and that danger ought not to be run. If the actual occurrence of exceptions had not been established, and if their occurrence were still only a reasonable expectation, it seems to me but right to the mother to protect her in every possible way from all risk. Even Mr. Hutchinson holds the mother of a child by a syphilitic father only to be rendered "in

some degree insusceptible to syphilis" and to have become "as a usual thing" "immune towards syphilis in a certain sense."[7] It matters nothing as I see it, and changes nothing, to regard a mother who gets a chancre from her syphilitic child as getting a second attack or a second infection of syphilis, which seems to be Mr. Hutchinson's view, that is, if I understand him correctly. A woman receives from vaccination something which renders her different from an unvaccinated person in respect of exposure to infection from small-pox—just as carrying a syphilitic fœtus does to the woman who carries it in regard to infection from syphilis—but I do not suppose that any one would advise a vaccinated woman to put herself unnecessarily in the way of being infected with small-pox, nor would we, if she did expose herself and became infected, call it a "second attack" or "second infection." I admit that "the something" which is received from vaccination and "the something" which is received from carrying a syphilitic fœtus may not be of the same potency as regards infection from small-pox and syphilis respectively. But the difference is one only of degree; and at the most the mother of the syphilitic fœtus is only less liable to infection from syphilis than the vaccinated woman is to infection from small-pox. My position is that, as the protection of the mother from syphilis is not complete, she ought never to be exposed to the risk, even if the reason for doing so were much stronger than that which is adduced by Mr. Hutchinson, and which seems to me altogether insufficient.

Welbeck-street, W.

TRANSFUSION OF SALINE FLUID INTO THE AXILLARY CELLULAR TISSUE IN CASES OF SEVERE HÆMORRHAGE.

BY ARTHUR H. DODD, L.R.C.P. LOND., M.R.C.S. ENG., L.S.A. LOND.

THE credit of this method of treatment is due to Mr. Thomas H. Morse of Norwich, and it was owing to his suggestions some time ago that I became aware of it. The instrument used is a very slight modification of Mr. Arbuthnot Lane's transfusion apparatus, made by Messrs. Down Brothers, the only difference being that a sharp-pointed needle of a little stouter make is required instead of the blunt one used for introduction into a vein, and the ordinary saline solution is used—i.e., a teaspoonful of common salt to the pint of boiled water cooled down to the proper temperature (100° F.). Having fitted the needle, tube, and syringe together, fill the latter with the solution, then force the steel point of the needle through the skin of the axilla deep enough to move freely into the cellular tissue, and slowly and gently force the fluid into the cellular tissue. Refill the syringe and proceed again until a pint or more has been used. The following are brief notes of a successful case in my own practice.

In February last I was sent for one evening about 7 P.M. to attend a multipara, as the nurse was alarmed at the excessive hæmorrhage which had taken place during the preceding two hours without apparently any progress being made in the labour. I found the patient had lost an enormous quantity of blood and was in a dangerous condition, being blanched and pulseless, and the pains, which had been going on regularly for several hours previously, had now entirely left her. Upon examination I found the os only partially dilated and the membranes protruding, but no presentation detectable. I ruptured the membranes, a large quantity of liquor amnii escaping, and I found that the cause of the hæmorrhage was right partial placenta prævia. She was now in an exceedingly critical condition, vomiting, in a cold clammy perspiration, with sighing respirations, the bowels acting involuntarily, and she was pulseless, semi-conscious, and apparently rapidly sinking. Two subcutaneous injections of ether were given without the slightest improvement. Dr. Treutler, who kindly saw the case with me and lent me his assistance, agreed that no further interference in the labour was at present justifiable. Remembering Mr. Morse's suggestions, and having my instrument within easy distance, we performed transfusion according to his method, injecting about a pint, although I must confess without the remotest idea of benefiting the patient, as we considered the case beyond our assistance. However, after a very brief interval there were indications of slight improvement and a very feeble pulse was detectable at the radials. During the next two hours small quantities of warm milk and brandy were able to be taken at frequent intervals. After that time there were decided symptoms of rallying and benefit from the transfusion and pains returned. By examination a vertex presentation could be made out, and ergotinine ($\frac{1}{10}$ gr.) was injected and we delivered with forceps.

It may be interesting to note that the child (female) was stillborn and very large, weighing eight pounds and three-quarters and measuring twenty-one and a half inches in length. It was in a state of well-marked rigor mortis, the stiffness of the limbs and body adding considerably to the difficulty of completing delivery, which was accomplished at 12 45 A.M. The movements of the child were last felt at 6 P.M. The placenta was easily removed, and the position of the part whence the hæmorrhage occurred found well-marked on its border. The patient made an uninterrupted recovery, assisted by taking iron in the form of Blaud's pills (bi-palatinoids) for several weeks.

The results of the transfusion were rapid absorption of the saline fluid (hardly any swelling remaining at the end of two hours) and decided and rapid improvement of the urgent symptoms, thus enabling the patient to take minute quantities of nourishment; and its advantages are the quick, ready, and easy application of the method which could be managed any time single-handed. Mr. Morse has had two successful cases, one being for a pulseless patient, due to hæmorrhage as a result of extra-uterine fœtation, and he says "that the pulse became quite a good one in fifteen minutes," and he further suggests the use of this method "before certain operations in collapsed conditions due to hæmorrhage," and on future occasions he intends performing the operation in both axillæ.

West Brighton, Sussex.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CASE OF OBTURATOR HERNIA SUCCESSFULLY TREATED BY COPIOUS ENEMATA.

BY C. W. MONRO GRIER, M.B., C.M. EDIN.,
MEDICAL OFFICER, MEVAGISSEY DISTRICT, ST. AUSTELL UNION.

ON June 25th, 1895, a fisherman aged thirty-eight years was carried home from his boat suffering great pain along the line of the adductor muscles to the knee of the left leg. The day before he had hobbled to his boat in pain in the same region, and had been obliged to remain on his hands and knees until he was carried ashore, as stated. The bowels had not been moved for two days. A slight sense of fulness to the inner side of the femoral vessels, inability to extend the thigh, the great pain at the groin, complete loss of appetite, and a sense of nausea, with the tongue dried in the centre, suggested the diagnosis, the inguinal and femoral canals being clear. Having tried moderate taxis without result I ordered an enema of a gallon of warm water, which was injected almost without the patient being aware of it, so complete was the loss of sensation in the lower bowel. After a quarter of an hour, there being no desire to defecate, he was asked to make an effort to move the bowel, with the result that about a pint of hardly discoloured water was passed. He was then put on morphia, belladonna, and tincture of chloroform, which somewhat relieved his pain and induced sleep for an hour or two. On June 26th, 10 A.M., I found that nothing had been passed by the bowel during the night. The tongue was drier and the condition was evidently worse. The temperature was 101° F. and the pulse was 112. I gave another enema of a gallon of warm water and applied taxis, with the result that I fancied I heard and felt a slight gurgle under my thumb. He now stated that he was not suffering so much pain. There was still loss of sensation in the lower bowel, but on the patient's trying to evacuate the enema about two pints were passed with a

Digitized by Google

few hard fæces, which I thought (from his passing so small a portion of the enema) must have been lying below the seat of injury. The morphia was continued. In the evening there was considerable pain, but no further motion by the bowel; a considerable amount of urine was passed. The tongue was still dry. I ordered elixir of cascara sagrada, two drachms, to be repeated in four hours. On June 27th no motion had been passed during the night, but much urine. The tongue was still dry and the pulse, temperature, and condition were generally about the same as they had been on the previous morning. The fulness at the inner side of the femoral vessels had disappeared and the pain at that part was not so severe. I considered that the hernia had been reduced and that there was probably stricture of the gut in the region injured. I again gave an enema of a gallon, rolled the patient gently from side to side of the bed, and kneaded the abdomen. The combined efforts induced considerable peristaltic action, with much pain and desire to defecate, with the result that there was a free motion of the bowels with plenty of fæces. On June 28th the patient was generally better; the bowels had been moved once freely during the night, but there was still some abdominal distress. On the 29th and 30th he was better, and on July 1st he went out for a walk. The diet throughout consisted of well-boiled gruel, beef-tea, and milk.

Polpier, Mevagissey, Cornwall.

CASE OF CHRONIC NEPHRITIS IN WHICH THE SEVERE DROPSY DISAPPEARED AFTER PERSISTING FOR NEARLY TWELVE MONTHS.

By MATTHEW SHIRLEY, L.R.C.P. EDIN., L.F.P.&S. GLASG.,
MEDICAL OFFICER TO THE HUNSLET UNION WORKHOUSE.

A MAN aged thirty-two years was in the Skipton Union Workhouse in November, 1893, and onwards for thirteen weeks under Dr. Wylie and Mr. Welsh. He was swollen to the waist from below upwards and his urine on boiling was nearly solid with albumin. In March, 1894, he was under Mr. Atkinson of Romaldkirk, near Barnard Castle. On Sept. 19th his condition was rather worse and he went to the General Infirmary, Leeds. His urine was examined then, but his condition did not improve. On the 20th he came into the Union Workhouse at Hunslet, when his condition was as follows. There was anasarca from head to foot; the urine on boiling became solid; the patient was very restless; he had a dry, hacking cough; and was sleepless and muttering. Pilocarpine was given. On Oct. 4th there was no change for the better. The patient had been sweating, was still swollen, and very restless. The pilocarpine was given up. On the 11th the anasarca had become somewhat less. He was more cheerful and felt better. The urine was in the same condition and there were casts. On the 14th the anasarca was less all over and the urine was the same. On the 15th there was no albumin on boiling, but about one-fifth albumin on settling after adding nitric acid. The anasarca was quite gone and the improvement continued. On the 25th the patient was up and partook of eggs, liquor carnis, a mutton chop, and some milk. He was cheerful, and there was no return of any symptom. There were no casts and the albumin was lessening.

A NOTE ON FIFTY CASES OF INFLUENZA.

By H. W. WEBBER, M.S., M.D. LOND.

SEVERAL interesting points with regard to the symptoms and complications occurring in influenza have at times been raised by correspondents of THE LANCET, notably—(1) throat affections, (2) the presence of skin eruptions, and (3) the treatment of the disease. My experience in fifty consecutive cases of influenza observed during the last epidemic is that throat trouble has been present in the majority, although the subjective symptoms of this have been slight, no pain on swallowing (or very little) being complained of. On examination the fauces, uvula, soft palate, and pharynx showed a general redness of peculiar dusky colour and dry appearance; the intensity of the inflammation has been fairly proportionate to the degree of pyrexia, though its slow subsidence has been in marked contrast to the usually rapid (from twenty-four to forty-eight hours) fall of temperature. I have not observed swelling of the tonsils beyond a slight congestion accompanying the above condition in any case. In twenty-two of the cases redness of the skin was present. This was of the nature of a congestive erythema, well-marked when pyrexia was at its height and then of deep-red colour, the skin being burning hot to the touch, this disappearing with the fall of temperature and leaving the patient anæmic. In nearly all the cases it was most intense on the face, arms, and hands. No desquamation of any sort has followed in any case. In four of the cases I have observed vesicular herpes; in three this made its appearance on the fall of temperature, in the fourth the patient when first seen was still going about, having a temperature of 102·2° F. on the fourth day of the disease. In one case the eruption was profuse, involving the alæ and columna nasi and both lips; in the other three a crop of vesicles about the size of a sixpence was situated on the lower lip. My treatment with all has been—(*a*) during the acute stage confinement to bed, liquid diet, and a mixture of salicylate of soda, bicarbonate of potash, and liquor ammoniæ acetatis, with the addition of a little sal volatile; the latter counteracts the depressing tendency of the salicylate of soda and the influenza virus and seems to lessen the headache, and this, when persisting after the acute stage, I have always found relieved by five-grain doses of antipyrin given every four hours if required; (*b*) after the subsidence of pyrexia by quinine with strychnia; and (*c*) special complications, such as bronchial catarrh, which has been frequent, require suitable treatment.

THE ROYAL EYE HOSPITAL, SOUTHWARK.

A CASE OF DIPHTHERITIC CONJUNCTIVITIS.

(Under the care of Dr. W. J. COLLINS.)

THE following notes of a case occurring in Dr. Collins's practice at the Royal Eye Hospital, Southwark, deserve record as showing very completely how the local, constitutional, and bacteriological phenomena which we recognise as diphtheritic have their exact counterpart when the seat of the initial lesion is the conjunctival mucous membrane instead of the faucial. The disease is said to be most common in Germany, but we sometimes get very severe cases in this country as evidenced by the record of this one. We are indebted to Dr. J. W. H. Eyre, clinical assistant, for the notes and the account of the bacteriological investigation.

The patient was a male child aged two years and was first seen by Dr. W. J. Collins on Feb. 10th, 1896. The history given by the mother was that the child's left eye had begun to be inflamed three days previously. The right eye became affected the next day, but it was not until the day previously to her visit to the hospital that the lids had swollen to any extent. When first seen both eyes were affected, the lids being swollen, red, and painful, and difficult to separate on account of the brawny infiltration of the surrounding subcutaneous tissues. On separating the lids by means of retractors the ocular conjunctiva was found to be injected and much chemosed; the palpebral portion was congested and thickened and presented patches of pale greyish-yellow membranous exudation, giving one the impression that a strong caustic had been recently applied. This membrane stripped off easily, leaving a raw bleeding surface below. The corneæ were slightly hazy, but the surface epithelium remained unbroken. A thin milky-white discharge, slight in quantity, exuded from

Digitized by Google

the palpebral fissures, excoriating the skin of the cheek. Such was the local condition; added to this the child was obviously ill, being flushed, restless, and irritable, with a temperature of 102° F. and a pulse of 100; he had albuminous urine. No throat symptoms were present, nor could any history of exposure to contagion be elicited. The treatment adopted was the isolation of the child and the use of a lotion of hydrochlorate of quinine (five grains to the ounce) every half hour, an ointment of boracic acid being subsequently applied to the edges of the lids. Once a day the membrane was stripped off and the whole of the palpebral conjunctiva painted with a solution of silver nitrate (twenty grains to the ounce). The membrane at the commencement of the treatment re-formed in the course of a few hours, but after the first day or two the exudation process was much less rapid and entirely ceased in seven days. As the cornea remained a little hazy drops of sulphate of atropia (two grains to the ounce) were instilled from Feb. 17th to 24th. At the end of this period the cornea and conjunctiva had regained their normal appearance. One month later the child was again examined, when there was found to be marked paresis of the extensor muscles of the left hand and forearm. The mother stated that the condition had been more marked a week or so before and was then improving.

Bacteriological examination.—When the child was first seen (Feb. 10th) cover-slip preparations made directly from the serous discharge revealed the presence of numerous polynuclear leucocytes, some staphylococci, and slender bacilli. These last measured about 1·75 μ in length, and from the irregular manner in which they took the stain (carbolic methylene blue) presented a somewhat beaded appearance. None were clubbed, and morphologically the bacilli might equally well have been either the bacillus diphtheriæ or the xerosis bacillus. A blood serum tube was therefore inoculated with some of the discharge taken from the left lower conjunctival fornix and incubated at 37° C. for eighteen hours. At the end of that period the resulting growth consisted of small raised circular or rather spherical colonies of an opaque white colour, which microscopically consisted entirely of what appeared to be the long variety of the Klebs-Löffler bacillus. Some larger colonies of staphylococci were also present. From this first culture agar plates were made and the bacillus diphtheriæ was isolated. A subculture in bouillon was next prepared and after forty-eight hours' incubation at 37° C. examined and found to be pure. One c.c. was then inoculated into the subcutaneous tissue of the abdomen of a guinea-pig weighing 250 grammes (Feb. 18th); eighty-three hours later (the 22nd) the guinea-pig was dead, and post mortem the local œdema and serous effusions usually associated with death resulting from inoculation of the bacillus diphtheriæ were observed. Cover-slip preparations were made and blood serum tubes inoculated with the conjunctival secretion from each eye when the membrane had finally disappeared (Feb. 24th), but with negative results—the staphylococcus epidermidis albus alone being present. This observation was again repeated on the 27th with a like result.

STATION HOSPITAL, SIRDARPUR, CENTRAL INDIA.

A CASE OF ATROPINE POISONING AND A DOUBTFUL ONE OF STRAMONIUM POISONING.

(Under the care of Surgeon-Lieutenant-Colonel J. DUKE.)

THERE is probably no country in the world which affords so much employment and instruction to the toxicologist as India, and we in Great Britain gain considerable advantage from a perusal of notes of cases such as the following. It is to be regretted that the time of our medical brethren in the East is so much taken up with practical administrative duties that little is left for the record of clinical observations. Much which we can ill afford to lose should be published but is daily lost to the world owing to want of opportunity on the part of the overworked observer. The dose of atropine in the first case was unusually small in amount to produce such severe symptoms, and owing to the method of administration its effects were exceptionally difficult to overcome.

CASE 1. *Atropine poisoning.*—On June 21st a Sepoy aged forty years who was otherwise in sound health was admitted for lumbago attributed to a fall from a tree, the patient alighting on his buttocks. On the 25th five minims of liquor atropiæ P.B. (strength four grains to the ounce) were ordered as an injection into the loin to relieve the pain. The injection was given at 4.30 P.M., and fifteen minutes later he complained of dryness of the throat, giddiness, a feeling of intoxication, and distress. At 5 P.M. the pupils were dilated and the body was trembling. He picked at the bedclothes and was restless, throwing his arms about and moaning. If allowed to rise he wandered about, picking at the walls with his fingers. He was conscious and able to answer questions in a drunken manner. At 7 P.M. Surgeon-Lieutenant-Colonel Duke saw him. He was more or less insensible and restless, tossing about in bed and throwing his arms about wildly, his actions being restrained by two attendants. The noisy, pleasing delirium mentioned by Murrell was present. The pupils were dilated, the pulse was full and strong, and the respiration was thoracic and abdominal. He had apparently a desire to micturate, but was unable to do so. At 7.30 P.M. one-sixth of a grain of pilocarpine was injected subcutaneously; no physiological effects followed. At 8 P.M. the same quantity of pilocarpine was given without any physiological effects, but the delirium seemed to be less. At 9.15 P.M. the patient was quieter, but he was still quite unconscious. The pupils were widely dilated. The pulse was now small, thready, and compressible. At 9.45 P.M. one-sixth of a grain of pilocarpine was again injected; there were no physiological effects, but the delirium was much lessened. Mustard plasters were applied with bandages to the calves of the legs. At 10.15 P.M. the following enema was given: rum, two ounces; liquor ammoniæ fortior, five minims; and very hot coffee, one pint. At 10.30 P.M. the patient suddenly became conscious and answered questions. He micturated freely. At 12 midnight he was sitting up; he was a little shaky in his movements, but quite rational and answered all questions. He said that "something had happened to him, but what that something was had gone."

CASE 2 *Stramonium poisoning (a doubtful case)*—A Sepoy aged thirty-five years was carried to hospital on Sept. 15th. On admission he was insensible. His temperature was 101·6° F., indicating fever; the attendant symptoms were, however, unusual. His decubitus was peculiar; he lay boring his head into the pillow and trying to hide it; he picked at the bedclothes with his fingers and was generally restless. He tried to get up, but was unable to stand. His pupils were neither dilated nor contracted. Inquiry showed that on the previous day he had worked with a fatigue party engaged in removing mud from a river, and that he was in good health on the evening preceding his attack. He was said to take one pill of opium three times a day. The diagnosis was possibly cerebral effusion. There was no history of poison. A blister was applied to the head, calomel with antifebrine was administered internally, and mustard plasters were applied to the calves. At 7 P.M. the temperature was 102°. At 8 P.M., owing to retention, twelve ounces of urine were drawn off with a catheter. At 9 P.M. his symptoms were serious and much the same; a castor oil enema was ordered. On Sept. 16th at 8 A.M. the bowels had been moved three times and there had been vomiting once. His behaviour was still most curious. He was more or less delirious and started when the hand was placed on his body. If roused he looked up and then buried his head in the clothes. As these symptoms corresponded to the description of datura poisoning given in the text-books one-sixth of a grain of pilocarpine in ten minims of water was injected. The usual physiological effects followed and the patient became quieter and more conscious. At 6 P.M. the same quantity of pilocarpine was given, after which he was much quieter. On Sept. 17th at 8 A.M. he was conscious and spoke rationally; he walked and took food. He was discharged to duty on the 24th.

Remarks by Surgeon-Lieutenant-Colonel DUKE.—The patient in Case 1 was a confirmed Indian hemp smoker and drinker of twenty years' standing. When the Indian Hemp Commission sat in 1893 he contributed to it the principal written evidence sent from Sirdarpur. Whether this habit renders a man liable to be specially affected by atropine is an open question. My own impression at the time (considering the smallness of the dose and the severity of the symptoms) that the Indian hemp habit had created an idiosyncrasy in this patient is only a conjecture. I can find no mention of it in the text-books. With a view of determining whether the gunja habit hindered the action of pilocarpine, four days after his recovery pilocarpine was again used as follows. On June 29th at 4 P.M. one-sixth of a grain of pilocarpine was injected; at 4.5 P.M. there were slight forehead

Digitized by Google

perspiration and slight salivation; at 4.10 P.M. free salivation was present; and at 4 30 P.M. the salivation had ceased. The saliva secreted amounted to three ounces, giving the full and usual effects of this drug. This experiment proves that (1) the bhang habit in no way checked the action of pilocarpine; and (2) the atropine poison alone prevented its action, the dose of pilocarpine being insufficient. Regarding the treatment of atropine poison, in his book on Poisons Murrell advises the injection of half a grain of pilocarpine every half-hour. In this case only one-sixth of a grain doses were given, as at first it seemed incredible to me that one-twenty-fourth of a grain of atropine could produce dangerous results. Yet at 10 P.M. the symptoms were somewhat alarming. Had half a grain been used at first it seems probable that consciousness would have been restored in a brief period. I have lately tried atropine in three cases of local pain, using two minims of the solution in three minims of water. In all instances slight physiological symptoms rapidly developed. Martindale and Westcott, in their Extra Pharmacopœia (fourth edition) quote as follows: "Inject. atrop. hypd.: dose 1 to 4 minims or more." The condition of the patient in Case 2 at one time seemed to be very serious, and the symptoms were most puzzling. A high temperature indicated fever, but the symptoms of delirium, retention of urine, picking at the bedclothes, and pillow-boring were not such as occur in fever of a few hours' duration. On Sept. 14th, when at fatigue duty, he probably ate some datura seeds, and the rise in the temperature was caused by a chill caught in the river bed. The case was probably one of mild datura poisoning accidentally associated with fever, both producing a combination of symptoms difficult to diagnose.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Leucosarcoma of Choroid — Cataract Extraction and Gout.— On the Origin of Ruptures in Detached Retinæ.— Cyst of Orbit.— Acquired Nystagmus in other Occupations than that of Coal-mining, with Cases and Remarks.

AN ordinary meeting of this society was held on June 11th, Mr. E. NETTLESHIP being in the chair.

Dr. ROCKLIFFE (Hull) described a case of Leucosarcoma of the Choroid. The patient was a man aged forty-two who had previously had a fall on the occiput. Three years afterwards he fancied he saw "black specks" before his eyes, but no inconvenience was remarked until nine months later, when he discovered it was necessary either to close the left eye or to hold a book slantingly in order to read with comfort. He had a good family history and always enjoyed good health. His vision when first seen was normal in the right eye and $\frac{6}{12}$, with + 1 D. = 4 J. in the left. Pupil natural, field normal. There was no scotoma; the colour sense was good; and the fundus was normal. The above condition continued, with the exception of increase of defect of vision, for two months, when the perimeter showed a defective field and the retina was loose around and below the yellow spot. A fortnight later the retina showed marked detachment with defined margin extending from above the yellow spot downwards nearly to periphery and almost to the optic disc. There was no other symptom of orbital tumour. No choroidal vessels were to be seen beneath the detached retina. No tremulousness of iris. Sarcoma of the choroid was diagnosed and immediate excision advised. This was done four months after he had first noticed the defect of vision. The specimen (shown) exposed a round-celled unpigmented sarcoma, measuring 13 mm. by 4 mm., originating to the outer side of the optic disc in the deeper layers of the choroid. Dr. Rockliffe alluded to several recorded cases and inferred that leucosarcomata of the choroid usually originated from the deeper layers of the choroid at the posterior pole of the eye, that they were not easily diagnosed in their earlier stage, and although the adult eye seemed to be the most common as in other sarcomata it might vary from twenty months to seventy years and their development was usually rapid. He estimated that about one in every 100 cases of sarcoma of the choroid was unpigmented and that the majority proved fatal by metastasis.—Mr. MARSHALL, estimating from a limited number of cases coming under his notice at Moorfields, stated that as high a proportion as 22 per cent. of the sarcomas were devoid of pigment. Mr. Lawford and Mr. Treacher Collins, in the cases they had collected, estimated the proportion of unpigmented sarcomas as 11 per cent.—Mr. JOHN GRIFFITH had met with eight unpigmented specimens among thirty-five sarcomas affecting the choroid. He was of opinion that the growth originated in the chorio capillaris and not in the deep layers of the choroid.—The PRESIDENT thought that the difficulty of diagnosis in this case lay in the great extent of the tumour and its slight depth; it illustrated the importance of estimating refraction carefully in cases where vision had undergone a change.

Dr. ROCKLIFFE also related a case of Cataract Extraction complicated by Gout. The patient six hours after the operation had alarming and copious hæmatemesis, followed on the second day by an acute attack of gout in the hands and feet, and immense chemosis of the conjunctiva on the sixth day. The patient, however, made a good recovery from the extraction, and on May 15th, two months after the operation, his vision was $\frac{6}{9}$ and J 1, and he had read the lessons in his village church on the previous Sunday using the operated eye with the greatest ease.—The PRESIDENT was of opinion that attacks of gout following cataract extraction were not very uncommon, even in hospital patients, but were not generally mentioned in the notes because they did not affect the after recovery of the eye; he had met with several instances.—Mr. W. LANG referred to four cases in which patients had suffered from an acute joint attack just after cataract extraction, but in none of them had there been any ocular manifestations of gout.

Mr. TREACHER COLLINS read a paper on the Origin of Ruptures in Detached Retinæ. He first referred to the views of Graefe and Raehlman that the ruptures were due to tension of the subretinal fluid, and of Leber and Nordensen that they were produced by traction on the retina from shrinking bands in the vitreous. He then read an account of, and showed some lantern slides of, two specimens, which afforded definite anatomical proof of the occasional formation of these ruptures in the way inferred by Elschning from the appearances seen by him in two cases he had examined ophthalmoscopically. In each of the eyes described by Mr. Collins the retina was apparently completely detached and lay folded in the centre of the globe. In each he had found, however, on microscopical examination, a patch of atrophied retina intimately adherent to the choroid in the yellow spot region, and completely isolated from the rest of the retina. It would seem, therefore, in these two cases that there had first been some central retino-choroiditis which had, over a localised area, so firmly united the retina and choroid that when subsequently the former became detached the adherent patch of it was torn away and remained attached to the choroid, a hole thus being formed in the detached retina.—Mr. W. LANG spoke of three cases of detached retina under his care in which there had been holes in the yellow spot region. He inquired whether adhesions occurred elsewhere than at the yellow spot. In many of the ruptures there was no loss of retina, only laceration.—Mr. COLLINS readily admitted that there might be other ways in which rupture occurred besides the one he had described; he merely wished to give this anatomical evidence in support of the theory of Elschning.

Mr. R. W. DOYNE communicated for Mr. W. E. CANT of Jerusalem an account of Cyst of the Orbit. The patient, a man, went to the British Ophthalmic Hospital, Jerusalem, with proptosis. Vision was not much impaired. There was a firm, solid substance to be felt in the seat of the lacrymal gland, and deeper than this a fluid tumour was felt occupying the orbit and passing through the bone to the temporal fossa, so that the eyeball became more prominent with the movements of the jaw. The tumour was incised, and found to be a cyst lying beneath the periosteum in the outer wall of the orbit; the bone between it and the temporal fossa had been absorbed. After considerable delay the cavity granulated.—Dr. ARGYLL ROBERTSON said that dermoid cysts of the orbit adherent to the bone often caused great difficulty. It had been suggested to him by Dr. Robertson of Singapore to make a free incision into them, evacuate their contents, and insert a small piece of lunar caustic. This caused brief suppuration, and in a few days the cyst wall was loosened and could be withdrawn entire by forceps.

Mr. SIMEON SNELL (Sheffield) read a paper on Acquired

Digitized by Google

Nystagmus in other Occupations than Coalmining, with cases and remarks. The labour bestowed in recent years in the investigation of the etiology of miners' nystagmus, was bearing fruit in demonstrating the existence of a similar occupation—neurosis in the workers in other employments than that of coalmining. The constrained position in which the collier worked would, perhaps, remain *par excellence* the most conducive to the production, in frequency and severity, of acquired nystagmus, but the case he related showed that nystagmus and weariness of the ocular elevators were already to be found in a variety of occupations. He referred to the interesting historical fact that Michael Angelo suffered in his eyes from painting the vault of the Sistine Chapel, and he wrote a sonnet which Mr. Snell quoted, describing the constrained attitude he was compelled to occupy at his work. Vasari, suffered in a similar manner from painting the Medicean Palace. Mr. Snell mentioned that since recording his case of nystagmus in a compositor in 1891, 12 other cases, 5 of them compositors, had come under his observation. Three cases had been communicated to him by Mr. Priestley Smith, and 3 by Dr. Simons (Merthyr Tydvil), and Nieden had recorded an instance of acquired nystagmus in a plank cutter. The total number of cases referred to in the paper was 19, and comprised 6 compositors, 2 metal rollers, a platelayer, a plankcutter, a saw maker, a sanitary tube maker, a fitter, an ironfounder, a worker in a "cage" at a mine, 2 employés at a glass factory, a youth engaged at a confectionery warehouse, and a man employed at the screens at the surface of a coal mine. They varied much in degree, and in some there was more weariness of the ocular elevators than very noticeable nystagmus: but it was held that, as in the case of miners, the oscillations would have been more marked if the examinations had been made when the patients had been at work for some time. Generally speaking, the nystagmus was less marked than that met with in miners. Mr. Snell thought that attention having been drawn to the matter, nystagmus and strain or weariness in the elevators will be much more widely recognised as caused by different employments than was the case at present. The plan of investigation advocated was to get the patient to place himself in the position in which he worked, or better to see the patient actually at his employment. In conclusion, Mr. Snell remarked that he thought a main factor in the causation of "Academy headache" was the weariness induced in the ocular muscles by turning the gaze so frequently above the horizontal line. This could be compensated by a backward movement of the head.

The following living and card specimens were shown:—

Mr. SECKER WALKER: (1) Tumour of Optic Nerve; and (2) Cysticercus of Conjunctiva.

Dr. BELL TAYLOR: Cases of Cataract Extraction.

Mr. SILCOCK: Lymphangioma of Orbit.

Mr. LAWFORD: Pigmentation of Conjunctiva.

Mr. JULER: Macroblepharon.

Mr. HOLMES SPICER: Acute Double Optic Neuritis.

ABSTRACT OF THE BOWMAN LECTURE.

Vision and Retinal Perception.

Dr. H. SNELLEN, Professor of Ophthalmology in the University of Utrecht, delivered the Bowman Lecture on Vision and Retinal Perception before this society on June 12th.

After paying an eloquent tribute to the memory of Sir William Bowman and to his powers as a brilliant operator and scientific physician Dr. Snellen proceeded to consider the demands made by the State on ophthalmic surgeons at the present day in regard to the examination of candidates for the public services, and pointed out that England had taken the lead among nations in this matter. The Ophthalmological Society and the British Medical Association, having each of them investigated and reported on the subject, had succeeded in impressing the authorities with a knowledge of its importance. As tending to throw light on some of the questions of vision which were still undetermined, the lecturer went on to describe the result of some investigations on vision and retinal perception which he had recently been making. Alluding to the contention of Vierordt and others that it was better to express the acuity of vision by the square of the diameter of the retinal image rather than by its linear measurement, Dr. Snellen pointed out that while the recognition of form depends on more complicated considerations than can be expressed by the simple linear measure, yet the value of perception is not fully represented by the square measure of the retinal image, inasmuch as the perceptivity of the fovea is not equal all over, but diminishes from the centre outwards. Moreover, the act of vision was not confined to the perception of a stationary retinal image, because the movements of the eye brought every part of the image over the centre of the fovea and each muscular movement represented a linear measure. One of the most important questions was the dependence of acuteness of vision on the amount of illumination and the difficulty of stating the amount of illumination, especially by daylight which varies so constantly. A fresh series of observations had been recently made on this subject at Utrecht under Dr. Snellen's direction. The observations were carried out by the light of a gas flame kept at a constant pressure by a special regulator and passed over benzine to secure constancy of illuminating power. The photometer of Leonhard Weber was used, by means of which it was possible to estimate the amount of light on any given surface without regard to the source of the light. It was found that when the illumination reached a certain degree of intensity the unprotected eye was unconscious of any further increase of luminosity: the maximum of vision was reached with a luminosity of 30 to 50 metre candles. With decrease of illumination the vision soon diminished and changes in intensity were quickly perceived. The acuteness of binocular vision was higher with every degree of illumination than that of monocular vision, but the difference was not equal to doubling the intensity of the light, as had been stated. A further series of observations was made with the photometer in order to arrive at the intensity of daylight at different times in various workshops. In a printing business the want of light impeded the work of compositors when it fell below 15 metre candles and if at dusk the intensity did not fall below 15 metre candles there would be in full daylight an intensity of 30 to 50 metre candles, direct sunlight being excluded; for coarser kinds of work, like that of carpenters and blacksmiths, a minimum of 10 metre candles was enough. In the new Ophthalmic Hospital at Utrecht special arrangements for lighting the operating room had been made; the highest demands on the visual powers were made where operations on the eye had to be performed. Considering that the visual power is heightened by adaptation of the eye for a weaker light than that falling on the observed object, the walls, ceiling, and floor of the operating-room had been painted black and light was only admitted through a window directly on to the patient. By this means the operator had at his disposal the maximum of his vision; there was the additional advantage that the troublesome reflections from the cornea were avoided, and the patient's gaze could be kept fixed in any direction by the flame of a candle which could be well seen against the dark background of the walls. The adaptation of the eye to light was next considered. Like the size of the pupil, the sensibility of the retina changed under the influence of light and darkness. The time required for adaptation corresponds with the period of anatomical changes in the retina—namely, the formation and disappearance of the visual purple, the changes in the pigment cells and cones. Observations were made with a small screen illuminated by an electric spark of great intensity. The moment the light flashed forth there appeared on the screen a bright flood of light, which rapidly increased in intensity and then faded away in about a corresponding period of time. During the increase in intensity the light had the same colour as the screen; during the decrease it had the opposite colour. This occurred with all colours, provided they were sufficiently saturated. Mixed colours were seen as such, followed during the decrease by opposite mixed colours. It was found that absolute white is very rare; white paper has always a yellow or blue tint, and dead black appears as saturated blue followed by yellow. These two phases were succeeded by a third phase of much longer duration. The after-image corresponding to this third phase was very feebly coloured and was mostly of a reddish-brown colour. As long as this red-brown after-image persisted there was anæsthesia for objective light, such as was given by a plate of luminous paint. The third phase corresponds to the more commonly studied after-images, which arise by long-continued looking at a bright object and its projection on a white surface. This interesting succession of light and dark of the after-image can also be seen on looking at a very

Digitized by Google

feeble light in a darkened room; if this be done the light slowly fades and disappears altogether, but with the slightest movement of the eye it suddenly reappears, owing to its falling on a fresh part of the retina. If the light be looked at while movement of the eye is carefully avoided after disappearance it slowly and gradually returns to its former brightness and then slowly fades again, so that a continual slow succession of light and darkness can be observed. These phenomena are to be looked upon as an example of the reciprocal effect of the adjoining parts of the retina on each other; according to Herring's theory of colour vision there is a continuous reciprocal influence between the spot in the retina where the image is observed and the adjoining parts, due to a modification of the visual substance which undergoes alternate assimilation and dissimilation. Assimilation and dissimilation can temporarily become equally great and by reciprocal influence neutralise each other.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Some Psychological Consequences of Suppressed Menstruation. — Successful Transfusion after Extreme Hæmorrhage.

A MEETING of this society was held on June 11th, Dr. CLEMENT GODSON, President, being in the chair.

Mr. R. O'CALLAGHAN showed two specimens of Fibromyoma of the Uterus removed by the Extra-peritoneal Method of Hysterectomy. Both patients made a good recovery.

Dr. MACPHERSON LAWRIE showed two specimens of Carcinoma of the Uterus removed by Vaginal Hysterectomy.

Dr. FANCOURT BARNES read a paper on some of the Psychological Consequences of Suppressed Menstruation. He recalled the fact that the menopause, whether natural or artificial, was liable to be associated with mental disturbance; and that the natural climacteric had a more marked influence in this respect than the sudden inhibition of menstruation by accidental causes. He then briefly reviewed the process of menstruation from the point of view of the variations in vascular tension which it occasioned and which could be demonstrated by the sphygmograph. He believed that the increased vascular tension was in some measure responsible for the mental disturbances found. This was illustrated by the following case. The patient was aged twenty-seven and was single. A year before coming under observation she had a great shock from the death of her father, whereupon menstruation ceased. She became very depressed and weak-minded, while her physical condition deteriorated. She had undergone the routine medical treatment for amenorrhœa, so he advised examination under ether with a view to surgical intervention. Finding the os uteri not well developed, he divided the cervix bilaterally and applied tinctura iodi to the endometrium. A similar application was made twice a week for the next three weeks. A month after the operation menstruation came on freely and painlessly. She at once began to improve mentally and physically, and some months after was perfectly well.—Dr. LEITH NAPIER said he had seen cases such as that recorded in the paper, and thought Dr. Barnes's argument a sound one. He recalled the case of a young girl in whom the sudden suppression of menstruation following on a chill was associated with severe neuralgia and complete blindness. The latter shortly passed off and menstruation was re-established. In another case, after removal of the appendages, the patient menstruated regularly for two and a half years; as the flow then became profuse he curetted the uterus. Menstruation ceased and symptoms of the menopause came on. They were so severe that he ordered an emmenagogue; the flow returned and the symptoms ceased. When she left off taking the medicine amenorrhœa again resulted, with the same symptoms as before.—Dr. ROBERT BARNES thought the case well illustrated the association between menstruation and the nervous system. In a paper read before the society some years ago he dwelt on the relation of menstruation to insanity. If the present case had got into an asylum she would probably have stayed there, for he regarded it as a great fault in the organisation of our asylums that there was no provision for the examination of such cases. Not only should women be examined before being committed to asylums, but the asylum authorities should employ skilled gynæcologists to attend to pelvic disease occurring among the inmates, whether or not the mental condition was likely to be benefited thereby. As it was he regarded asylum medical officers as among the most absolute of the profession, and once a woman was placed in an asylum she was likely to stay there. He often recalled a precept he learned in Paris in his student days: "Messieurs, interrogez tous les fonctions"; he thought it was one they should always bear in mind.—Dr. ROUTH had seen a great number of these cases where the neurotic condition was so marked that unless the patients were in good hands they were very likely to drift into an asylum. As a rule no one knew less of the gynæcological conditions in the insane than the medical attendants in asylums; more than once he had been called in to see patients and had been able to save some of them from spending their days as lunatics. Dr. Barnes's paper would have done much if it did nothing else but call attention to the fact that many kinds of insanity were due to suppression of the menses.—Dr. MACNAUGHTON JONES said they must remember that suppression of the menses was sometimes the result, and not the cause, of mental disturbance. They should not too broadly impeach the heads of asylums, and some of the remarks made by previous speakers on this point were not just. He knew personally many asylum medial officers, and was convinced that they were just as alive to the coördination of mental and sexual conditions as anyone present, and were just as anxious to arrive at the truth of the matter and secure the well-being of the patients. The question of treatment was often very difficult, for the patient's safety had to be thought of, and it was sometimes necessary to put her under temporary restraint. He remembered a case in which a young girl walked into the river while under treatment for the restoration of her menstrual functions. Dr. Barnes's remarks about the variations in vascular tension were interesting; the high tension might show itself in other directions, as in disturbances of the eyes, ears, nose, or throat.—Dr. FANCOURT BARNES, in reply, said his object had been to show the value of surgical methods in some cases which were generally looked on as purely medical. The case was, no doubt, an extreme one, and of course they would not wish, as a rule, to resort to surgical measures in the case of young girls. He had had good results from similar treatment in cases of dysmenorrhœa.

Dr. E. HOLLAND read a note on a case of Successful Transfusion after Extreme Hæmorrhage. Two hours after an ordinary ovariotomy the house physician at the hospital for Women, Soho-square, noticed signs of severe and rapidly progressive hæmorrhage and sent for Dr. Holland. On his arrival the patient was pulseless. He at once re-opened the abdomen and re-tied the pedicle. By this time the patient had ceased breathing. Dr. R. T. Smith carried on artificial respiration and Mr. Scott Elliott, then senior house physician at the hospital, rapidly and skilfully performed transfusion, whilst he (Dr. Holland) was occupied with cleansing the flooded abdomen. After a pint of saline solution had been introduced a faint sigh was heard and the pulse was felt, thready and unstable. After the second pint it was a little stronger and the hands became warmer. After three pints had fully passed into the veins the patient opened her eyes, rolled her head, and had a well-sustained pulse of 108, and was put back to bed. Chloride of sodium solution was also used for washing out the abdomen and about a pint was purposely left in. The patient sat up in bed on the eighteenth day and left the hospital convalescent on the thirty-fifth day.

EDINBURGH OBSTETRICAL SOCIETY.

Fœtus Compressus.—"The Indigestion of Breast Babies."—Peripheral Neuritis in Pregnancy.—Abortion of Four Fœtuses, one Monstrous.—Cyst on the Back of an Infant simulating the Head of another Infant.

A MEETING of this society was held on June 10th, when, in the absence of the President, Dr. HALLIDAY CROOM occupied the chair.

Dr. J. W. BALLANTYNE exhibited a Fœtus Compressus. It was accompanied by two placental masses with the smaller of which this fœtus was connected. It had evidently died about the third month; the other fœtus reached the seventh month and at birth showed signs of having been dead for some time.

Dr. JAMES CARMICHAEL read a paper entitled "The

Digitized by Google

Indigestion of Breast Babies." In alluding to the digestive troubles of bottle-fed infants he advocated the establishment of a milk laboratory in Edinburgh similar to the establishments of the larger cities of America. Sterilised milk was prepared and cream obtained by the centrifugal separator in these places, and milk might be analysed at small cost. A healthy child nursed by a healthy mother only rarely suffered from indigestion, but numerous causes might injuriously affect both. Defective hygienic conditions, low-lying houses, and insanitary drainage might affect the health of the mother and thus act on the child. General debility in the mother interfered with lactation; this might be induced by over child-bearing or it might be the result of the excessive mental training of girls during school life. Poor women who were often overworked and badly fed made inefficient nurses. So, also, many women in the upper classes with its luxury were often unable to nurse their children. Ill-health produced by any disease will interfere with proper lactation. Galactorrhœa or the constant flow of watery milk was evidently due to an over-excitability of the secretory functions and its causation thus associated with the nervous system. The milk was insufficient for the proper nourishment of the infant. Whenever the milk of the mother was defective in quantity or quality the child did not thrive or grow at the normal rate; the infant became soft and flabby, was always crying, and never appeared satisfied. The digestion was upset and vomiting was not infrequent; the stools were generally loose, pale, and often of an ashy-grey or greenish colour and with an excess of mucus. The undigested curd was present in little granular masses. As a rule the indigestion of milk was more frequently intestinal than gastric, diarrhœa being more common than vomiting; this was largely due to indigestion of the fatty and proteid elements of the milk. Irregular suckling was one of the commonest causes of indigestion in infants; it might occur from over-anxiety on the part of the mother, giving the infant the breast whenever the child cried; or it might be due to the milk being too poor in quality. In treating these cases the physician should first ascertain the cause, inquiring into the health of the mother and her habits and carefully examining the breasts, the milk, and the stools of the infant. During menstruation the milk on analysis showed deterioration in quality, and might give rise to a disturbance, often of a trivial nature, in the child. On the cessation of the menses the milk generally returned to a normal condition. In many cases menstruation was not a bar to nursing. It was necessary to wean the child if frequency occurred. The mother should take her usual plain and mixed dietary during nursing and a due amount of open-air exercise. Mothers were sometimes too ready on slight excuse to give up the nursing, but they should always be discouraged from doing so. If the milk was deficient in quantity the medical attendant should inspire the mother with hope that she might be able to nurse her child, and should increase the amount of liquid and easily-digested food she was taking. If there was too much milk the fluids must be reduced and the solids in her dietary increased. Irregular suckling should be prohibited. If the solids in the milk were deficient the child ought to be given the breast more frequently and the mother prevented from over-exerting herself and not allowed to take too much fluid. To decrease the solids the child should be nursed at longer intervals and the mother prescribed more exercise and more fluid nourishment. Increase of fat indicated the need of less animal food in the dietary and the reverse if there was too little cream. If the child was being too frequently applied to the breast some sterilised water should be given at times instead.—Dr. UNDERHILL spoke of the troubles attending the rearing of infants by wet-nurses and of the benefits obtained by giving the mother encouragement as to her capability of nursing the child.—Dr. KEPPIE PATERSON alluded to the necessity of examining the saline constituents of the milk, referring to a case seen in Berlin where the infant had refused the left breast and was being reared on the right. The mother stated that the milk from the left was salt, and on investigation this was found to be correct.—Dr. HALLIDAY CROOM said that in most cases it was not from want of willingness that mothers did not nurse their children, but because they could not, though he believed it was much better for them to do so.—Dr. JAMES RITCHIE, Dr. CHURCH, and Dr. BALLANTYNE also took part in the discussion.

Dr. GEORGE ELDER read a paper on Peripheral Neuritis in Pregnancy. He detailed the history of two cases. One was seen at the eighth month and the other at delivery, and both had suffered since the sixth month from the symptoms. There were tingling and loss of feeling in the fingers and loss of power, as shown in dropping articles from the hands; the hands were cold and there was impairment of the perception of heat. The arms were affected, and in one case the cutaneous nerves of the haunch and in the other the feet were also affected. There was no albumin or sugar in the urine and no evidence of alcoholism or syphilis. Recovery quickly occurred after labour. In referring to the literature of the subject there were two divisions—the polyneuritis of the puerperium and that of pregnancy. The former was due to septicæmia or the direct injury of the pelvic nerves by the pressure of the head or forceps, or by inflammatory exudation involving the nerves. The polyneuritis of pregnancy had symptoms corresponding to ordinary alcoholic peripheral neuritis. It usually began with paræsthesiæ more or less severe in the extremities, then paresis affecting especially the flexors of the wrist and foot, with the electrical reactions corresponding to the rapidity of the disease; and there were also, perhaps, trophic lesions. After eliminating the ordinary causes of neuritis—alcoholism, diphtheria, syphilis, lead, arsenic, &c.—he concluded that these cases were due to the pregnant condition and also because the neuritis disappeared after labour. During pregnancy there was more metabolism and a larger quantity of effete products was present in the blood, and this was the probable cause by poisoning the nerve cells in the spinal cord. There was little doubt that it was a peripheral neuritis, but as to the exact nature of the poison there was not the slightest evidence. Two fatal cases had been reported, and if the disease was seriously advancing it might be necessary to induce labour.—Dr. CULLEN remarked that the rarity of the condition during pregnancy rather pointed to that state acting as a preventive to the disease.—Dr. KEPPIE PATERSON alluded to a case where the symptoms commenced at the middle of pregnancy before there could be any pressure on the renal veins; the neuritis was complicated with anasarca in the later months. No albuminuria was present. The patient was a multipara, and the only explanation was that in this pregnancy she carried twins. He believed this disease to be due to insufficiency of kidney-action; in this case the kidneys had excretory power for one but were over-taxed with two children *in utero*.—Dr. MILNE MURRAY mentioned the case of a patient suffering from neuritis, which disappeared with the recurrence of pregnancy, and after delivery the symptoms returned. The neuritis was ultimately found to be due to the drinking of eau de Cologne.—Dr. LACKIE referred to a patient who had influenza with severe neuritis, and where pregnancy so aggravated the condition that the induction of premature labour was discussed. That, however, occurred naturally, and the patient recovered after a very prolonged convalescence.—Dr. HALLIDAY CROOM believed that pregnancy had some influence in preventing neuritis. A case of Raynaud's disease had been under his care where the symptoms were very much mitigated by the presence of pregnancy.

Dr. GUNSBURG of Charkov, Russia, sent a paper on a case of Abortion of Four Fœtuses, one of which was monstrous; also one on a Cyst on the Back of an Infant simulating the head of another Infant. These papers were translated and communicated by Dr. J. W. BALLANTYNE.

THE ROYAL SOUTH HANTS INFIRMARY AND THE POOR-LAW.—At the last meeting of the South Stoneham (Hants) board of guardians a resolution of much practical utility was arrived at. A letter was received from the management of the above-named institution at Southampton drawing attention to the scheme of alterations and additions to the infirmary which has been already mentioned. The estimate of the cost stands at £19,000. In view of the value of the infirmary to the suffering poor of the county the chairman of the governors appealed earnestly for help. The guardians already subscribe £15 per annum to the funds of the infirmary, but it was felt that its aid to the rates was such that a further grant of £10 per year would be justified. It was unanimously decided to subscribe £25 per year for three years as an aid to the efforts of the governors of the institution.

Reviews and Notices of Books.

Argon and Newton: a Realisation. By Lieutenant-Colonel W. SEDGWICK. London: W. B. Whittingham and Co., Limited. 1896. Price 7*s.* 6*d.*

LIEUTENANT-COLONEL W. SEDGWICK, late of the Royal Engineers, is most emphatically a materialist or realist, at any rate, in his views of atoms. He believes, with Newton, "that God in the beginning formed matter in solid, massy, impenetrable, movable particles ..... and that these primitive particles being solids are ..... so very hard as never to wear or break in pieces," &c. "Hard atoms," indeed, is his thesis, which, like the atoms, is also hard (to understand). Their existence, however, according to the author, is supported by the discovery of argon and helion. He urged in a previous work ("Force as an Entity") that valent metalloid atoms had undergone a process of shaping, and had been formed out of the atoms of pre-exisiting inactive elements. Now argon and helion have come to show, he adds, that inactive elements of some kind are in actual existence. They are like unshapen bricks, so to speak, which will not take a convenient place in the structure. He attempts to find this place and to put them in proper position, although it should be remarked that their elementary nature is as yet by no means settled; but "this cannot be done without perfect quietness," and "the difficulty of obtaining perfect quietness is undoubtedly great, and we have to plead for it." If only Mr. Jacoby's Street Noises Bill —— "but that is another story." We hope this pleading will not be in vain, but the effort will in no wise be assisted by raising questions (as is done in the preface) of national defence, which the author regards as a related subject of the question of reality. He speaks also "of fluid corpuscles" as the "mediating entities" which Philo employed to form a connexion between God and the world; but they are employed in "Argon and Newton" to form a connexion also between the evil one and the world. Those who desire something funny and incomprehensible to read should secure a copy of this volume.

Middlesex Hospital: Reports of the Medical, Surgical, and Pathological Registrars for the year 1894. London: H. K. Lewis, 136, Gower-street, W.C. 1895. Price 2*s.* 6*d.* net.

THIS volume contains a summary and statistical tables of the various diseases and injuries for which patients were treated during the year 1894. It is thus a valuable contribution to medical literature, and we are able to judge of the effects of treatment, &c., as set forth in an impartial manner. There are no papers by any members of the medical staff; indeed, there is no list of the staff published in the volume. This, we hope, the committee responsible for the reports will remedy in future issues, as it is interesting to know the names of members of a hospital staff during any one year, and we do not know any more satisfactory place for future reference than the report of the hospital for the year. The medical report by Dr. F. J. Wethered shows that 1618 patients were under treatment in the medical wards during the year, and the percentage mortality was 11·42, and the average stay of each patient in hospital 26·77 days. Forty-five cases of diphtheria were admitted and treated, with a mortality of 26·66 per cent. The antitoxin treatment was adopted in 9 cases, 2 of which died. Twenty-four cases of typhlitis were admitted during the year; 3 of these were transferred for operation. Amongst the cases which are specially abstracted we note typhus fever, pyæmia from middle ear disease terminating in recovery without operation, although the hip underwent spontaneous dislocation; Landry's paralysis, from which the patient recovered; actinomycosis involving the skin; actinomycosis of cheek, &c. From the surgical report, by Mr. John Murray, we learn that 1839 cases were under treatment in the surgical (including ophthalmic) wards, the mortality for the year being 8·5 per cent., but exclusive of deaths from malignant disease only 3·3 per cent. The average stay in hospital was 28·91 days. The special abstracts of interesting cases consist almost entirely of diseases of the abdomen, a series of operations on the kidney being especially instructive. There are apparently several cases treated in the surgical wards which in most hospitals are handed over to the gynæcological department. The report of the pathologist, Dr. A. F. Voelcker, contains a short record of 286 necropsies. This is a carefully written abstract; the observations are reported in the order in which they were made and not in a recognised grouping. An interesting table is that of abnormalities found during the post-mortem examinations of the year, the patients having died from other causes. We should like to see a report issued by every hospital on the same lines as this one. At present there are several hospitals where doubtless the practice is satisfactory, but there is no evidence to that effect before the medical profession. All institutions supported by charity where operations are performed or acute diseases received for treatment should give a yearly account of the results obtained within their walls in order that the medical profession may say whether the expenditure is justified.

Foods: their Composition and Analysis. By A. WYNTER BLYTH, M.R.C.S.Eng., F.I.C., F.C.S. Fourth edition, revised and enlarged. London: Charles Griffin and Co., Limited, Exeter-street, Strand. 1896. Price 21*s.*

WITH very few exceptions the adulteration of food is no longer a clumsy practice; it has become an art the resources of which are oftentimes exceedingly subtle, and which aim at precluding as far as possible the analyst from discovering the existence or exact extent of the fraud. In this matter the public owe a debt of gratitude to the Society of Public Analysts for bringing to light new methods of fraud and for placing at the disposal of the public analyst new and more accurate methods for its detection. The same admirable end is advanced by Mr. Wynter Blyth's most valuable work, inasmuch as it affords a safe guide and complete reference on this most important section of the subject. Further, Mr. Wynter Blyth is qualified as barrister, medical officer of health, and analyst, so that his work combines a practical knowledge, not merely of the chemistry of the subject, but also of its legal and its hygienic aspect. It was inevitable that a new edition would have to undergo considerable revision and enlargement in view of the enormous progress made in recent years in analytical chemistry, especially in its application to the examination of foods, but the author has succeeded remarkably well in keeping the dimensions of the volume within the limits of handy size. Nor is this at the expense of useful material or of latest developments. There are references, we find, as recent as a few months ago—as, for example, to Mr. Dibdin's paper read before the Society of Public Analysts relating to an improved method of microscopically examining and estimating the suspended impurities of water. The chapter on Water is an illustration of the important advances that have been made since the issue of the previous edition in estimating the fitness of a supply for drinking purposes. Thus the cultivation methods which are of service in differentiating pathogenic from non-pathogenic organisms in water are plainly described. In the section on Cocoa we observe that the author does not animadvert upon the use of alkali, while in the chapter on Coffee no reference is made to the so-called "essences." It

Digitized by Google

is well known that many of these are worthless, but honest preparations are also to be had. A tradesman has no right to sell a preparation stated to be made from coffee into the composition of which coffee never at any time or in any form entered. Coffee essences, we think, should be subject to the operation of the Act. In the description of the methods used for the detection of adulterated butter the glycerol soda modification of the Reichert process is omitted. The process offers important advantages, not the least of which is the saving of time in effecting complete saponification. A description of Lovibond's tintometer would have been useful in the section on Colour. We believe this instrument will be of distinct service in the valuation of foodstuffs when its merits have been scientifically investigated. Finally, we should like to have found a chapter generalising on the use of antiseptics as preservatives of food. Mr. Blyth's work is simply indispensable in the analyst's laboratory, where it will prove, as we have found it to prove, a constant and reliable source of reference on all matters pertaining to the practical examination of food.

Public Health Laboratory Work. By HENRY R. KENWOOD, M.B.Edin., D.P.H., F.C.S. Second edition with Illustrations. London: H. K. Lewis, 136, Gower-street, W.C. 1896. Price 10*s.* 6*d.*

THIS useful manual has run into a second edition, and the few blemishes (mostly technical) occurring in the first edition have been eliminated, while some processes described before have been replaced by others "and a considerable amount of new material has been added without increasing the size of the book." As its title implies, the work is one essentially for the bench, and the processes described are reliable and the conclusions on the whole are sound. In Chapter IV. the author enters a vigorous and, to some extent, plausible defence in favour of the value of a chemical examination as an aid in diagnosing impure water supplies. He regards organic impurity in quantity detectable by chemical analysis as an inevitable concomitant of specific micro-organisms. This view receives little support, however, in practice, as, for example, in the case of the contamination of the Worthing supply a few years ago, which led to a disastrous epidemic of typhoid fever. A chemical analysis by Dr. Dupré led this water to be regarded as free from reproach, but a bacteriological examination by Dr. Klein reversed this opinion. The author obviously makes a confusion of statement on page 145 when he states that alkaline waters naturally charged with carbonic acid contain sodium carbonate and bicarbonate. The only printer's error we noticed occurs on page 15, where methyl orange is spelt "meltyl" orange. The book very suitably meets the needs of students preparing for examinations in public health.

LIBRARY TABLE.

The Co-Education of the Sexes. By MABEL HAWTREY. London: Kegan Paul, Trench, Trübner, and Co., Limited. 1896.—This is a sensible book by a sensible woman. Miss Hawtrey has gone thoroughly into the subject and comes rightly, we think, to the conclusion that the co-education of the sexes is not desirable except in the case of quite young children or of young men and women, but that for boys and girls during the years when they are developing it is unsuitable. There are two separate chapters upon the education of boys and girls respectively which are well worth the attention of parents and guardians. Miss Hawtrey disapproves strongly of corporal punishment for girls. It either, she says, damages their nervous systems or else hardens all sensitive feeling so as to destroy their feminine instincts.

Practical Chemistry. By STEVENSON MACADAM, Jun., F.I.C., F.C.S. Second edition. Edinburgh: Printed at the Darien Press. 1895.—The object of this "short treatise" is evidently to enable the student to proceed to practical work, as the examination of simple salt, before he has grasped general principles. This is clear, from the remark in the preface that the formulæ expressing the nature of the reactions have been relegated to the end of the book, "so that the student, while doing actual practical work, may not be troubled (*sic*) with matter which is not practical and which he cannot properly comprehend till he has become somewhat advanced." We do not approve of this topsy-turvy plan, although doubtless the book itself is a good practical guide.

The *London Manual*, 1896-97, published at 125, Fleet-street. Price 1*s.*—London now covers such a large area and the governing machinery is so complicated—we believe there are over 400 governing authorities—that a manual explaining the functions and describing the work of all the public bodies in the metropolis and suburbs must be useful to all citizens. The second edition, which lies before us, contains the names of the vestrymen elected last month, thus bringing this excellent new year-book thoroughly up to date. The book also contains a great deal of information which while not necessarily relating to public bodies is of interest to householders.

Guy's Hospital Gazette (Festival Number).—The editors of this journal, have, with that energy and acumen which characterises them, issued a special Festival Number. It gives a full account of the great festival dinner and an interesting sketch of the history of the hospital. We observe an apology for the cloak-room arrangements at the dinner. That these were very defective there is no doubt, but we see that they were under the control of the Institute authorities who are not infrequently remiss in such matters.

JOURNALS AND REVIEWS.

The Journal of Experimental Medicine. Edited by WILLIAM H. WELCH, M.D. Vol. I., No. 2, April, 1896. New York: D. Appleton and Co. Subscription price per volume £1 1*s.*—The articles contained in this number are: 1. A Study of the Bacillus (Leptothrix?) Pyogenes Filiformis (Nova Species) and of its Pathogenic Origin, by Simon Flexner, M.D., with a plate. This pleomorphic micro-organism is described with much care. It was found in a laboratory rabbit, and the infection appeared to have taken place after delivery by the genital tract. The bacillus stains irregularly with all the aniline dyes. It is non-motile and is killed by exposure for five minutes to a temperature of 55°C. Inoculations made with it proved fatal, many abscesses resulting in different organs. 2. Observations on the Innervation of the Sublingual and Submaxillary Glands, by G. Carl Huber, M.D., of Michigan. Dr. Huber has employed the double Golgi-Cajal and the Ehrlich-Bethe methods of staining with very good results. He is in general accord with Langley in the presence and character of the ganglion cells found in connexion with the chorda tympani and the submaxillary ganglion. The axis cylinder processes of the lymphatic cells of the submaxillary ganglia may be seen to be continuous with small bundles of thin nerve fibres many of which are varicose and run along the side of the ducts. The smaller ducts come to be surrounded by a tolerably dense plexus of fine nerve fibres. From the plexus strands of two, three, or more fibres, or single fibres, are given off and can be followed between the alveoli, where they unite to form a perialveolar or epilamellar plexus. The ultimate fibrils seem to end on or between the gland cells in minute nodules or granules. The sympathetic fibres accompanying the gland artery end on

Digitized by Google

the vessels. 3. W. T. Porter: A New Method for the Study of the Intra-cardiac Pressure Curve. This is an ingenious arrangement of two Hürthle membrane manometers, one of which is connected with one tube of a double cannula and can by contact with a pair of cups containing mercury make a magnet close a stopcock connected with the second tube of the cannula. By altering the position of the lever of the first manometer and thus changing the moment at which the wire shall make the circuit and open the second manometer any particular part of the intra-ventricular curve can be studied. 4. The Rotary Properties of some Vegetable Proteids, by Arthur C. Alexander, Ph.D. The proteids examined were hemp globulin and the globulins obtained from flax and the Brazil nut. 5. Thomas B. Aldrich, Ph.D.: A Chemical Study of the Secretion of the Anal Glands of Mephitis Mephitica (Common Skunk), with remarks on the physiological properties of the secretion. 6. F. S. Conant and H. L. Clark: On the Accelerator and Inhibitory Nerves to the Crab's Heart. 7. Lewellys F. Barker: A Case of Circumscribed Unilateral and Elective Sensory Paralysis—that is, one in which only certain of the functions of the sensory nerves are abolished.

In the *Veterinary Journal and Annals of Comparative Pathology* for June is reproduced Nocard's account of An Experimental Study on the Translucent Tubercles of the Lung in Glandered Horses. This is especially interesting from the fact that in animals in which the symptoms of glanders are doubtful, but which react to mallein, there are discovered on post-mortem examination translucent tubercles which contain very few glanders bacilli, and which, therefore, have sometimes been overlooked as resulting from the action of this organism. Glanders in which such tubercles are present can apparently be cured, in a certain proportion of cases at least, by the injection of mallein. Another important point brought out in this paper is that glanders is easily propagated through the digestive organs. A couple of the notes in this number of the journal are strictly controversial and have to do rather with the rivalry which exists between the *Veterinarian* and the *Veterinary Journal* than with the outside veterinary and medical public. The suggested amendment of the Public Health Bill for Scotland as regards the employment of veterinary surgeons in the inspection of live stock in connexion with public health is again alluded to. A case of Tuberculosis in the Horse is described and many clinical cases are recorded. The remainder of the number is made up of reports of various veterinary associations, which seem at present to be concerned mainly with the question of veterinary education.

METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.

A WELL-ATTENDED meeting was held at Surrey House on the 11th inst. to bring before the public the claims of the Metropolitan Provident Medical Association on its support, financial and otherwise. Lord Battersea, who presided, stated in his opening remarks that the Association had now nineteen branches, ten of which were self-supporting; it had about 35,000 members enrolled, who contributed nearly £5000 a year in periodical payments. Lord Stamford moved the first resolution, to the effect that the work of the association was thus a great social benefit to the community. Mr. Claude Montefiore, in seconding, gave a clear account of its object, which, he said, was to provide medical aid, not for paupers, or for persons able to pay the ordinary fees of respectable medical practitioners, but for that vast class of people which lay between the two. It had two principles, and must prove that it was carrying out both before it could claim the help of the public: on the one hand it must promote thrift, and on the other it must supply good medical treatment. It must also deal fairly with the medical profession, without whose help and coöperation it could not carry on its work, and must protect the interests alike of its patients and of its medical staff. In view of this latter object it was careful to maintain a wage limit. Referring to the recent loss of that great philanthropist Baron de Hirsch, Mr. Montefiore mentioned that his munificent gift of £3000 made some few years ago had borne good fruit in the establishment of several flourishing branches. Dr. Hett spoke to the resolution from the point of view of a medical officer connected for twenty-two years with a provident dispensary. He spoke strongly of the benefit which had accrued to this dispensary when some years ago it was affiliated to the association, and mentioned with approval the principles which provide for the adequate representation of the medical staff on the local committee and for the payment of the medical men as a first charge on the funds of the dispensaries. He bore testimony also to the cordial relations which had always existed between himself and the members under his care.

Mr. W. F. Lawrence, M.P., moved the second resolution, which stated that the gratuitous and sometimes indiscriminate treatment of persons in the out-patient and casual departments of hospitals results in the creation of a pauperised spirit among the industrial classes, and that this evil is best met by the establishment of self-supporting provident dispensaries in coöperation with the hospitals.

Mr. Lucas, chairman of the Great Ormond-street Children's Hospital, urged the necessity and possibility of coöperation between the hospitals and the association in dealing with the out-patient problem.

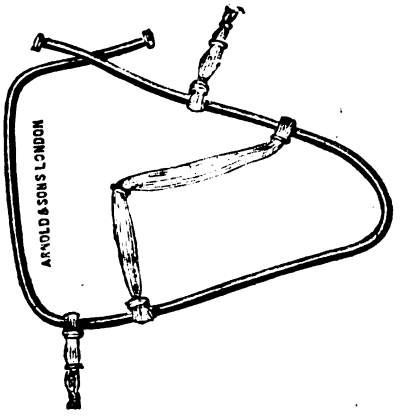
Mr. Bousfield, chairman of the association, in thanking Lord Battersea for presiding, remarked that they had learnt much in their experience of nearly twenty years, and had now, he believed, done a great deal towards solving the difficult and important question of the provision of medical relief for the industrial classes and deserved the support given them by the late Baron de Hirsch, the trustees of the London Parochial charities, and others.

New Inventions.

A CARDIAC CYRTOMETER.

AFTER delimitation by percussion, auscultation, and palpation of the area of cardiac dulness, some physicians have used transparent paper for preserving a permanent reading of the outlines thus obtained. I have found it more convenient in practice to employ a piece of flexible tubing such as that used in Leiter's instruments, or a piece of metal capable of being easily adapted to the area mapped out, just as a similar cyrtometer is used to ascertain the shape of the thorax.

Messrs. Arnold and Sons of West Smithfield have constructed a cardiac cyrtometer for me furnished with strands of silk bearing metal rings which, in addition to enabling



one to note the dimensions of the heart, afford a means of noting accurately the relative position of the organ to such points as the episternal and xyphoid notches and the nipple, and also the extent of the superficial cardiac dulness. This simple instrument occupies little bulk, and by its means the above facts may be transferred by a pen or pencil to an ordinary notebook without the use of transfer paper.

ALEXANDER MORISON, M.D. Edin., &c
Upper Berkeley-street, W.

Digitized by Google

THE LANCET.

LONDON: SATURDAY, JUNE 27, 1896.

TEN years have passed since the General Medical Council was reinforced for the first time by representatives sent up to it directly from the whole profession. Until the Medical Act of 1886 the Council was composed entirely of the nominees of the various universities and corporations of the United Kingdom and certain persons selected by the Crown. When the duties which fall upon the General Medical Council are recalled, it will be patent to all that the source from which the addition to its strength was drawn was most reasonable. It is the five-fold business of the Council (1) to supervise medical education; (2) to inspect medical examinations; (3) to issue the British Pharmacopœia; (4) to keep a correct Register; and (5) to purge that Register of unseemly names by sitting in judgment upon the professional behaviour of persons contained in it. The second, third, and fourth of these duties might be efficiently discharged by a deliberative assembly of scientific scholiasts and experienced examiners—we speak in the abstract and without personal reference to the present Council—with adequate clerical assistance, although the general body of the profession would still feel that they had an undeniable right to a voice in a matter of such extreme importance as the conduct of the tests which the aspirant to professional enrolment must undergo. But the first and fifth duties clearly demand from the Council a more intimate knowledge of the practical side of the medical man's life than an assembly whose learned pedagogy was unleavened could be expected to display. To supervise the complete education of the profession requires more than the habits of the schoolmaster or the learning of the professor. It requires a knowledge of the after-life of the rank and file of the profession. The examiners, generally and rightly drawn from the consultant classes, are able to provide that candidates should attain to a certain standard, but they are not able to gauge whether that standard does not sometimes necessitate the learning on the part of those candidates of things that are unnecessary in the real battle of life, while perhaps there have been omitted from their curriculum certain things the knowledge of which would have been found valuable in practice. Direct representatives would rightly look upon it as their more particular charge to warn their colleagues on the Council of the actual equipment required by the general practitioner of the day. In a still greater degree should it devolve upon them to assist the Council in the discharge of its fifth and most painful duty—the management of penal cases. Here the representatives of the general practitioner have been of the utmost use in the deliberations of the Council, for it is the general practitioner who suffers most severely from the evils that are the outcome of improper rivalry and the absence of a high moral tone.

The present occasion is apt to the discussion of the question of direct representation because an election of direct representatives to the General Medical Council is imminent and because there will be on this occasion an introduction of new blood into the Council. Mr. WHEELHOUSE and Sir WALTER FOSTER, whose joint letter to the profession we published last week, have definitely decided not to offer themselves for re-election. These two gentlemen were, with Dr. JAMES GREY GLOVER, the original choice of the profession when first the boon of direct representation was granted. They have served two terms of five years, and in so doing have earned the gratitude of their enormous constituency by their aptitude for business and their devotion to the interests of the profession at large. It is with regret that we have learned their intention to retire, and we desire to record our belief that the reason why direct representation has been a success is as much because of the ready manner in which the first representatives of the profession at large fell into the work of the Council as because the principle on which their admission to the Council was granted is obviously fair and liberal. The profession will therefore have to select for itself two new representatives at least (for Dr. GLOVER, as will be seen by his letter which appears on page 1820 of the present issue, is offering himself for re-election) and at this juncture we cannot do better than repeat the words of Mr. WHEELHOUSE and Sir WALTER FOSTER in their letter of resignation—"..... We would urge you," they say, "to make very deliberate and careful choice of your future representatives, remembering the high order of the duties the Council is called upon to exercise, and when you have elected them to give them that moral support without which it is impossible for them efficiently to represent you." It is our duty to further such wise selection, and there is in our mind no doubt whatever that the first essential of a good direct representative must be that he should be in general practice. Let no one consider that this expression of opinion can be interpreted as a slight upon the services of Mr. WHEELHOUSE and Sir WALTER FOSTER, which we are fresh from extolling. Both these gentlemen were fully conversant with the wants of the general practitioner, and should anyone come forward possessing their knowledge of the *morale* and working of the profession his claims to be considered a good candidate would rank very high. But Mr. WHEELHOUSE and Sir WALTER FOSTER were pioneers. The new representatives will have the benefit of their example, and as they will be the choice virtually of the general practitioners of the country it is fitting that they should be themselves members of that order.

Three gentlemen place their names before the profession in our columns this week as candidates for the suffrages of their fellow practitioners, and there will certainly be additions to this number. Dr. GLOVER may confidently expect re-election, we hope. He shares with his two retiring colleagues the honour of having been an original representative and of having worthily supported the principle of direct representation. His work on the Council has been energetic and good, and his critical remarks on the reports of inspectors of examinations (embodied in the form of a statement to the Council under the title of "Gaps in

Digitized by Google

Medical Education") led to discussions upon which followed directly the extension of the curriculum to five years. Dr. GLOVER was also chairman of the committee of the Council which investigated the working of the medical aid associations and made itself aware of the evils associated with these institutions. These evils have recently been made very palpable to the profession by the series of articles which has appeared in our columns entitled "The Battle of the Clubs." The great interest which has been taken in this question by the profession proves its extreme importance, upon which we need scarcely lay any further stress; but this fact warrants us in saying that any candidate desiring to represent the profession must have the salient points of the question tightly in his intellectual grasp to be a good candidate. There remains one more reason why the profession would do well to re-elect Dr. GLOVER as one of their three representatives. It is apart from the work that he has done, it is apart from his special fitness for the post, it is a reason of expediency. It would be a pity that all the original direct representatives should be absent from the Council at once. With a break in the line there would be an absence of traditional experience and a loss consequently of power and of knowledge. We hope, therefore, that Dr. GLOVER will meet with the support that he seeks, and that there will be associated with him two practitioners not residing in London. As will be seen, the Lancashire and Cheshire Branch of the British Medical Association have passed a resolution approving the candidature of Dr. GLOVER, Dr. LOVELL DRAGE of Hatfield, and Dr. WOODCOCK of Manchester.

THE Committee which was appointed in 1892 by the Royal College of Physicians of London to revise the "Nomenclature of Diseases" has at length completed its labours, the result being the publication of the third edition of a work which deserves to be regarded as of the first importance to the profession of medicine both at home and abroad. The book, which extends to more than 500 pages, has been issued by HER MAJESTY'S Stationery Office, and we understand that the Treasury has sanctioned the gratuitous supply of a copy of it to every member of the medical profession whose address can be ascertained. The idea that led, nearly forty years ago, to the projection of a nomenclature of disease which should possess a national, or rather an international, character originated in the Army Medical Department, through whose representations, supported by those of the Hospitals Committee of the Epidemiological Society, the Royal College of Physicians of London was induced in the year 1857 to undertake the preparation of a Nomenclature of Diseases, on the understanding that it should be subject to periodical revision. The work was commenced forthwith, but in 1858 the meetings of the committee appointed for the work were suspended for five years in consequence of the passing of the Medical Act and the alterations thereby necessitated in the constitution of the College. The meetings were, however, resumed in 1863, but it was not till 1869 that the first edition of the Nomenclature was published.

The work of revision has evidently on this occasion been an exceptionally heavy one and has occupied four years from its inception in the early part of 1892. The details have been carried out in sections, the various groups of diseases having been dealt with by as many as twenty-four separate sub-committees. From the preface we learn that in the opinion of the Revision Committee one of the chief uses of the statistical registration of diseases on a wide scale is that it must tend to throw light upon the causes of disease, many of which causes, when duly recognised, may be capable of prevention, removal, or diminution. When a general and uniform nomenclature of disease has once been carefully framed, when we are sure that medical observation is occupying itself everywhere with the self-same diseases, the value of statistical tables becomes very high, as representing the course of events in disease under various circumstances of time, place, climate, &c.

The edition of the Nomenclature just issued, like its two predecessors, is suitable to all countries where the English language is in common use. For each name of a disease the corresponding term has been supplied in Latin, the fittest language for a nomenclature common to all the world. The equivalent terms in French and German have also been added as being the modern languages which are richest in medical learning and literature. It has been decided after careful consideration to omit the Italian version, since the Italian names of diseases do not differ greatly from the Latin on the one hand or the French on the other. In settling the list of names of diseases the least possible deviation has been made from those employed in the General Register Office of England, for otherwise the special forms there in use, which in their main features have varied little during the last half century, would require re-modelling or perhaps complete reconstruction. And, worse than this, the comparison of future with past returns would become perplexing, if not impracticable, and a damaging break would be caused in evidence which, in proportion as it is prolonged and continuous, becomes more and more trustworthy.

As regards classification, the general plan of the Nomenclature remains the same as in former editions. Diseases, in the aggregate, are divided into two chief categories—(1) general diseases, in place of the "morbi corporis universi" of the last edition, and (2) local diseases. But further division into groups and sub-groups, after the manner of the previous edition, has, we think, wisely been omitted on the ground that accuracy of nomenclature, rather than pathological classification, is the object to be aimed at in a work of this kind. Among changes made in the present edition in the classification of diseases we notice the restriction of the term "anthrax" to the disease previously named splenic fever or wool-sorter's disease, and the relegation of the morbid condition carbuncle, which had been previously confounded with anthrax, to a separate category. The disease formerly termed epidemic rose rash is now termed "Rubella," in deference to the opinion of physicians specially skilled in the diseases of children, the old name rötheln being still retained as a synonym. Diabetes insipidus (polyuria) and tetanus are now for the first time admitted as new names in the division of general diseases.

The section on Nervous Diseases has been entirely recast,

Digitized by Google

and so likewise have those relating to Diseases of the Digestive, Respiratory, and Integumentary Systems. The section on Surgical Operations has been rearranged, as has also the section on Malformations. The enumeration of tumours and morbid growths has undergone fundamental alteration in order to bring this group into harmony with modern classification. The class "cysts" has been retained in deference to usage and to the needs of registration, although it necessarily overlaps some other divisions of the nomenclature.

In the present edition the English has, for the first time, been separated from the Latin index. The English index, which is in some senses the real nomenclature, includes every name used in the work, and the Latin index, which is intended as a guide to those readers who are not conversant with the English language, contains the terms used in the Latin version of the nomenclature. Not being intended for purposes of registration the Latin is less complete than the English index, but it nevertheless contains the names of all distinct diseases and references to the chief divisions of the work. We must not omit to mention that the Latin version of the nomenclature, which had been commenced by Dr. GREENHILL, has been completed since his untimely death by Dr. PERRY, whose well-known ability as a classical scholar is a guarantee for the correctness of his work. The entire volume has been edited by the honorary secretary, Dr. PAYNE, upon whom, of course, has devolved the greater part of the labour of its compilation. In congratulating Dr. PAYNE and his colleagues on the completion of the present edition of the Nomenclature we may remark that it bears evidence of unusual care and thoroughness in its preparation. It is a piece of solid, valuable work, and we cannot speak of it in higher terms than by saying that it fully sustains the high character attained by the two editions which have preceded it.

THE calamitous loss of the *Drummond Castle* off the coast of Brest last week, with its tale of upwards of 240 persons drowned, suggests many reflections of various kinds. Some of these can only be advantageously discussed by navigators and naval architects, yet when these have said their say there will still be lessons to be drawn and enforced which have no reference to any technical questions, but reflect rather upon the system under which ocean traffic is carried on at the present day. It is, indeed, one of the most striking features of the present disaster that, meagre as are the details as yet made known, or indeed ever likely to come to light, they seem to prove conclusively that the terrible accident was not inevitable, but, on the contrary, might have been avoided by the exercise of sufficient caution. In saying this we do not cast the smallest blame upon the master or navigating officer of the ship. If it should hereafter become necessary to throw blame upon them it will be only after careful inquiry and on a basis of fact not yet made public. We do not, as at present informed, doubt that the ship was handled and navigated in accordance with the best professional practice, and it is on that account that we think it necessary to call attention to a state of things more dangerous than mere incompetency on the part of individuals because it is embodied in a system and affects the entire profession of the sea, good and bad alike.

The facts to which we refer are these. The great ship, equipped with most of the appliances that science can provide for the safety of her passengers, was nearing the completion of her voyage. She fell in with rainy weather upon a rocky coast and was carried far out of her course by cross-currents. In all other respects her circumstances were happy, and these are among the slightest and most ordinary of the inconveniences which beset the traffic of the sea. No one could imagine that any serious danger lurked in trifles such as these. Even the proximity of the coast ought not to have occasioned any inconvenience, for the coast is well lighted and the charted course lies at a safe distance from it, although near enough for the ship's bearings to be accurately determined by the assistance of the lights. Under such conditions a serious mishap is a bare possibility and nothing more, and that this is no merely theoretical view but one borne out by experience is proved by the fact that a wreck like that of last week is almost unprecedented, notwithstanding the enormous traffic which passes Ushant every year. Why, then, was the ill-fated *Drummond Castle* an exception to the all but invariable rule? The answer will come at once to light if we consider what precisely was happening on the captain's bridge upon that fateful evening. We have it on the testimony of the survivors that the captain was himself there, and it may be added with confidence that he was looking out for the Ushant light. It is a notably powerful light and can be detected forty or fifty miles away; nor is cloudy weather unfavourable to its efficiency, for at these great distances the light itself lies below the horizon and its whereabouts is betrayed only by the glare which it throws upon the clouds. Thus in cloudy weather it is, other things being equal, visible at a greater distance than when the sky is clear. In thick weather a syren supplements the obscured light. Now the commander of the *Drummond Castle* must have known as soon as darkness fell upon him and the Ushant light failed to shine out that he was out of his reckoning, and he must also have known that he was approaching more or less near to the French coast. The sense of danger must, therefore, have impressed itself upon his mind and the importance of ascertaining his exact position cannot have escaped him. Why did he not do so? The means were ready to his hand, for although sky and lighthouse were both obscured the sea bottom was within thirty fathoms of him, and his sounding line would have enabled him to ascertain his whereabouts just as well as his sextant if that had been available. If those means failed him there was still a perfectly secure course open to him, he might have put about and sailed into the open sea until such time as a view of the heavens gave him the opportunity of determining his position afresh and making a fair start for home. That he contemplated adopting some such course as this may be taken for granted, but unhappily be delayed adopting it until too late. Why this tenacity in the face of danger? Why this hesitation to admit that a voyage prosperous on the whole has not been wholly prosperous?

The answer doubtless is to be found in the success of our modern navigation. Steamers come and go by the

Digitized by Google

clock, and even after extended voyages like that from the Cape, they arrive, in the ordinary course, according to appointment with an exactitude that is wholly admirable. But such perfect working involves a certain amount of inconspicuous risk. With a standard of performance such as that to conform to the ship's master shrinks as from a crime from anything that involves the least delay and a deviation from his course seems to him, and naturally enough, to be a disguised calamity. When the alternative is deviation he naturally prefers to take some small risk and if now and again the risk is greater than he knows that is no great blame to him. How often a prosperous voyage is beset by little perils of this sort and is prosperously completed in spite of them sailors alone know. But what the public is concerned to ascertain is that those who encourage and require the mariner to follow the shortest course and keep time with the precision of a clock should also make it clear that he must not trust to his good fortune or economise time and coal at the expense of running even the smallest risk to the life of the ship and her passengers. Had there been a less inexorable rule about the date of arrival in port or a more inexorable one about keeping on the safe side of the charted course the captain of the *Drummond Castle* would not have needed to hesitate so long about taking strong measures with his errant ship and the great sorrow of this terrible shipwreck would not have fallen on two hemispheres.

Annotations.

"Ne quid nimis."

THE CASE OF SURGEON-CAPTAIN FOWLER.

ON the House of Commons going into Committee of Supply on the Army Estimates Sir Walter Foster moved the reduction of the salary of the Secretary of State for War in order to call attention to the case of Surgeon-Captain Fowler. A lively debate ensued, but we fail to see that any satisfactory explanation was afforded in the course of it to justify the severe measure that was adopted in regard to that officer. Surgeon-Captain Fowler had nearly ten years service and an unblemished record when, unfortunately for him, he was sent to Sheerness in June of last year to do duty in the camp there on the occasion of the training of a Militia regiment. The name of this regiment was not mentioned in the debate, but it is quite clear that some proceedings of a disgraceful nature occurred rendering it absolutely necessary to deal very severely with several officers who took part in them. This should not, however, be allowed to prejudice the consideration of the case of Surgeon-Captain Fowler. It appears that this officer's presence on the occasion was accidental and did not extend over a few minutes; that so far from in any way aiding and abetting the officers concerned he at once protested against the proceedings and succeeded in putting a stop to them; and that he appealed to the senior captain present, who at Surgeon-Captain Fowler's instigation undertook to report the matter to higher authority. We fail to see that so far any exception can be taken to the course this officer adopted. A court of inquiry was subsequently held, but we are not informed of what actually took place, or of the exact nature of the evidence given, beyond the fact that it is alleged there existed a sort of conspiracy among the officers concerned to conceal the truth from the authorities. We are not told whether Surgeon-Captain Fowler took any, and if so what, part in this concealment or misrepresentation of the real facts of the case. As far as we can understand—for the Under Secretary for War was very reticent and guarded in his statements—Surgeon-Captain Fowler is stated to have failed in his military duty in not having frankly and conscientiously stated all that he knew of the circumstances, with the names of those who were present on the occasion—of having, in fact, tried with other officers to hush up the whole affair. But it is quite possible that, without any idea of concealment or unworthy motive, Surgeon-Captain Fowler contented himself with stating the course he had already adopted in the matter. Mr. Brodrick did not seek to impute anything against this officer's professional character, but in respect of his sense of military duty and responsibility he did. The case, he added, had been fully considered, and every official, civil or military, felt the necessity of taking severe measures, and he went on to detail the punishments that had been inflicted upon numerous officers in order to show that Surgeon-Captain Fowler had not been exceptionally dealt with. There is no doubt that the matter was a very grave military scandal and that all the actors in it deserved to be most severely punished; but the point to be proved as regards Surgeon-Captain Fowler is whether he took any part in those proceedings beyond promptly protesting against them and stopping them, and reporting the circumstance to the senior combatant officer present and obtaining his assurance as to the action he would take in the matter. Why were not all the officers concerned tried by court martial, or if this were not deemed expedient in the public interest why was not the case—as regards Surgeon-Captain Fowler at any rate—submitted for the opinion of the law officers of the Crown or of the Judge Advocate General? Had either of these courses been adopted no doubt would have existed as to what were the real facts of the case, whereas there is, as Sir H. Campbell Bannerman very properly urged, considerable doubt in the minds of many people as to whether an injustice has not been done to an excellent and deserving medical officer.

THE UNIVERSITY OF LONDON.

A MEETING of Convocation of the University of London was held on Tuesday, the 23rd inst., when technical details of procedure formed the main business before the meeting. The election of a Fellow of the University—i.e., a member of the Senate—also took place, and much curiosity was felt as to the result of the election. By a tacit arrangement a Fellow is alternately selected in Arts and Laws and Medicine and Science whenever a vacancy has to be filled by Convocation. On this occasion it was the turn of the latter faculties, and so Sir Joseph Lister and Mr. Rivington were nominated. Both are graduates of the University, and Mr. Rivington was successful, obtaining a majority of 117 votes: 846 graduates voted for Sir Joseph Lister, and 963 for Mr. Rivington. The contest was throughout carried out on strictly political, as distinct from professional, lines. Sir Joseph Lister was brought forward as a candidate by those graduates who wish to see the present University transformed by having a Teaching University added to it, as recommended by the Cowper Commission, which also recommended that a Statutory Commission should be appointed to carry this out. Mr. Rivington's views are that the existing University should continue its useful work as an Imperial Examining Board and that a Teaching University should be a separate institution. He also urges that if any scheme of reconstitution of the University of London be adopted, it should be by charter in the usual manner and not by the exceptional method of a Statutory Commission. His election on Tuesday evidently shows that this is in accordance with the opinions of the majority of the graduates and will make the Lord President of the Council hesitate still longer before he accedes to the wishes of those who

Digitized by Google

urge him to appoint a Statutory Commission forthwith. It is regrettable, we think, that the election of a Fellow to represent the Faculty of Medicine in the Senate should be determined by such sectional differences, but with the existing tension of feeling in the University we see no way out of the difficulty. The Faculty of Arts, with its large and increasing majority of votes, has the decision in its hands, whatever may be the opinion of the medical graduates.

KING'S COLLEGE: PRESENTATION TO PROFESSOR CURNOW, M.D.

LAST Tuesday afternoon the operating theatre at King's College Hospital was the scene of an interesting ceremony on the occasion of a presentation to Dr. Curnow by his old pupils and students on his retirement from the office of Dean of the Medical Faculty after thirteen years' service. The chair was occupied, and the presentation made, by Mr. P. T. B. Beale, F.R.C.S. Mr. Beale, in making the presentation, referred to Dr. Curnow's valuable services in the department, laying particular stress on the kindly sympathy which the late Dean had invariably shown towards students who confided in him. Many a man at present in a position of importance might be said to owe his success in life to Dr. Curnow's kindly guidance and sound advice. The presentation consisted of an illuminated scroll, containing the names of many students past and present who had pursued their studies during his tenure of office, a handsome silver salver suitably engraved, and a complete tea and coffee service of very handsome workmanship and design. The subscribers were limited to those who had been students at the hospital during Dr. Curnow's deanship. Dr. Curnow, in warmly thanking the subscribers and those present for their great kindness, assured them that he would, as in the past, do anything he could to assist them in the pursuit of a peculiarly arduous profession.

THE PERILS OF DOING GOOD.

UPON June 19th, in the Southern Divisional Police-court of Dublin, Mr. Auchinleck of Harcourt-street was charged before Mr. Swifte, Q.C., with having committed an assault on a married woman named Lepper in the month of February last. Mrs. Lepper stated on examination that she was twenty-three years of age, married for about thirteen months, and had no children. Having suffered from illness last February she was recommended to consult Mr. Auchinleck and did so on two occasions, on the second of which she was assaulted. Mr. O'Shaughnessy, Q.C., in addressing the Court said that it was a fortunate thing in the interest of truth and to prevent the occurrence of shameful blackmail actions that he was entitled, under the Criminal Law Amendment Act of 1885, to examine the defendant, who would tell his worship that the woman first consulted him in the ordinary way; that on a subsequent occasion she requested to be examined and was examined, and that he had never used the expressions or done the acts imputed to him. There was a long delay about these proceedings. There were present in court two medical gentlemen of the highest eminence in their profession in the city, who would state that medical men had often the greatest difficulty in dealing with the maladies peculiar to women, and that charges such as had been made on the present occasion were very frequently made against medical men under similar circumstances. Mr. Auchinleck, the defendant, was now examined and deposed to the facts put forward by counsel, stating, moreover, that he had been for twenty-three years practising in the city of Dublin, his practice being largely in connexion with midwifery; that he was married and had a wife and five children who lived with him; and, finally, that in cases of this kind, leaving the question of blackmail out of the question, it was a fact well known in the profession that medical men never knew what women might possibly say or do. Dr. William Josiah Smyly, master of the Rotunda Hospital, and Dr. More Madden, obstetric physician to the Mater Misericordiæ Hospital, were also examined and supported Mr. Auchinleck in his statement that charges of the sort were likely to be made by married women under similar circumstances and that, in fact, it was one of the dangers connected with the treatment of married women suffering from such maladies. Dr. More Madden stated that he considered this woman to be labouring under a hallucination. Mr. Swifte, in dismissing the case, said from the bench that the question for him was whether he thought a jury would convict in the case of a man of irreproachable character favourably known in the city for twenty-three years. He thought that the delay in taking proceedings and the fact that Mrs. Lepper did not give any alarm or make any complaint at the time would weigh very much in the matter and prevent any jury from convicting in the case. We congratulate Mr. Auchinleck upon the result of this case. Charges of this kind are so easy to bring and so hard to refute that we almost think the wisest course would be for medical men to refuse to examine women except in the presence of a third person.

THE POLLUTION OF THE RIVER BRENT.

MOST Londoners, especially skaters, are familiar with that body of water known as the "Welsh Harp" reservoir, but probably it is not so generally known that the "lake" in question, which feeds the Regent Canal, was brought into existence by constructing a dam across the valley of the River Brent. One of the effects of this work has been to divert from the natural bed of this river much of the water which formerly found its way into it, and hence any pollutions of the stream are less diluted than they would otherwise be. The river, if such water as is let out from the reservoir can be dignified by that name, passes through or abuts upon several sanitary districts, and amongst them may be mentioned Willesden, Ealing, and Hanwell urban and Hendon and Brentford rural. Within recent years complaints as to the condition of the river hereabouts have been loud and long, and in 1893 Dr. Monckton Copeman, a medical inspector of the Local Government Board, made an inspection of the river. Dr. Copeman had no hesitation in pronouncing the condition of affairs eminently unsatisfactory. He found the bed of the river for some 300 yards below the reservoir completely dry, with the exception of two small pools some ten feet in diameter, and apparently no water had left the reservoir in this direction for several weeks. On following the bed of the channel for some distance down Dr. Copeman came upon what he states was practically, at that time, the source of the River Brent—i.e., the effluent of the Willesden sewage farm, samples of which contained much suspended matter and gave off a faint sickly smell. A short distance further down "the whole bed of the stream was absolutely black as if a river of ink had been flowing over it," a condition of affairs produced, it appears, by decomposition of the sewage effluent. At the point near to which the Grand Junction Canal crosses the Brent Dr. Copeman found "enormous heaps of London refuse" which, draining into the stream, fouled it to an extent which could only, he says, be appreciated by inspection. Further down the stream other pollutions were discovered, but it is needless to recapitulate them. Suffice it to say that Dr. Copeman reported amongst other things that the sewage effluents from districts abutting on the stream are for the most part "decidedly unsatisfactory," and that throughout the course of the stream crude sewage and putrescent fluids are discharged. In a word, the stream is much polluted and the abstraction

Digitized by Google

of water by the Regent Canal Company accentuates the nuisance. This condition of affairs should obviously be put an end to without delay. The fact of pollution is practically established by disinterested testimony. Who is to remedy it? The sanitary authorities whose districts abut on the stream have powers and responsibilities under the Rivers Pollution Acts; the Middlesex County Council has powers under a Local Government Act, 1888; and the Thames Conservancy is surely interested. Inasmuch, however, as some of the sanitary authorities are themselves contributing to the pollution, it appears to us that the authority best fitted to take action in a comprehensive sense is the Middlesex County Council, and we trust that they will awaken to the necessities of the situation. Obviously Dr. Copeman's report will be a most valuable weapon in their hands, and we are glad to see that the Hanwell Urban District Council is endeavouring to stir matters up.

ACTION AGAINST A DISTRICT COUNCIL.

AT Pontypridd, on June 17th, Judge Williams gave his decision in an action in which Mr. Sparnon, a tradesman of Llantrisant, claimed £50 damages from the Llantrisant and Llantwit Vardre Rural District Council for alleged injuries caused by the defendants' employés to his health and business, the action being brought in reference to a drain which was laid down by the defendants under plaintiff's premises, when chloride of lime was used for disinfection. His Honour said that the disinfectant was used in greater quantities than was required, Mr. Sparnon being obliged to leave his house, and the chloride of lime aggravated a disease from which he was suffering to such an extent that, according to the medical evidence, he was confined to his bed for two months and had been ailing ever since; and he further observed that he found that the defendants had knowledge of the plaintiff's state of health, and under the circumstances they should have consulted their medical officer of health as to what disinfectant was proper and in what quantities it should be used, but they persisted in the use of chloride of lime after they had received formal notice of its effects. His Honour assessed the damages at £25 4*s*., apportioned as follows: Personal injuries to plaintiff, £10 10*s*.; doctor's bill, apportioned, £10 10*s*.; one month's wages to the plaintiff's son, £4 4*s*., with costs.

ISOLATION DIFFICULTIES AT CHISWICK.

THE difficulty which sanitary authorities have to face in procuring sites for infectious hospitals is once more exemplified by the recent breakdown at Chiswick. The Duke of Devonshire at first promised to assist the urban council in the matter, although this offer of help was accompanied by conditions which were felt to be serious. Before, however, any attempt could be made to abate the stringency of these conditions he announced that any grant of land by him for the purpose in question would meet with much opposition from the residents and hence he could not voluntarily offer facilities in connexion with the intended scheme. Whether the Duke of Devonshire means that he will oppose any attempt to take his land or whether he wishes simply to imply that compulsory purchase under a provisional order must be resorted to as a matter of form so as to relieve him from responsibility is immaterial, for the expense of the latter method of procedure is in itself a barrier in the way. No one can complain of a landowner who feels that to sell land for an infectious hospital will not only depreciate the value of his estate but also cause great discontent on the part of those who have already erected houses on that estate; nevertheless the time must come when public health authorities will have to be afforded greater facilities in this matter. In the case of Chiswick no question of small-pox arose, so far as we can learn, and there is abundant evidence to show that, apart from small-pox, an infectious hospital which is properly administered does not involve any danger to the surrounding community; and, happily, we have in the case of small-pox an infinitely more potent means of prevention than small-pox hospitals have thus far shown themselves to be. It is, indeed, only with the steady advance of vaccination that the Gloucester epidemic has been dealt with to the extent already achieved, and the town council of that city admitted long ago that the attempt to get rid of the epidemic by means of isolation and disinfection had failed. It is essentially in regard to scarlet fever that the need of hospital accommodation for Chiswick has been shown to be wanting, and in England and Wales, whilst small-pox has of recent years only slain its tens or its hundreds, scarlet fever has numbered its victims annually by thousands.

THE CASE OF MR. R. B. ANDERSON.

WE learn with much pleasure that the Worshipful Society of Apothecaries has decided to receive a deputation of the Civil Rights Defence Committee, to be introduced by Lord Stamford, to place fully before the Master, Wardens, and Court of Assistants the facts of Mr. Anderson's case that amount to an infringement of the charter of the Hall and an invitation to unite in the work of the committee in defence of the rights of the Society. Such an infringement seems so incredible that we cannot wonder that the Society of Apothecaries has taken some time to grasp the reality. The reception of the deputation does not in itself, of course, pledge the Society to adopt any line, but we cannot doubt that when the Society realises the nature and extent of the violations of its charter it will decide to act constitutionally but vigorously in defence of its own rights and those of a grievously injured Licentiate and especially claim, as it is entitled to do, the coöperation of the other guilds and the Corporation of the City of London in the necessary measures to protect the rights of a city charter.

THE SECRETION OF THE SKUNK (MEPHITIS MEPHITICA).

AN interesting article on this subject appears in the second number of a new American journal, the *Journal of Experimental Medicine*, written by Dr. Thomas B. Aldrich. The investigation is all the more deserving of praise since it is one of the most repulsive that can be undertaken. The offensive character of the secretion has become a byword. It is discharged from two oval pouches about an inch long, situated on the sides of the rectum close to the anus, by two ducts which terminate at the top of little papillæ just inside the sphincter ani. The wall of the pouches consists of a fibrous investment, a muscular coat of striped fibres, a submucous coat, and a mucous membrane; the masses of glands are situated in the submucous layer. The glands are tubular and lined by cubical epithelium. They present strong analogies to the sudoriparous glands. The disgusting odour of the secretion is so intense that one of Dr. Aldrich's predecessors having collected a little for examination the whole College of the Johns Hopkins University rose in revolt, and he had to get rid of his material. Dr. Aldrich was more fortunate and was permitted to pursue his examination without interruption. The fluid secretion is clear, limpid, and golden-yellow or amber-coloured, having a characteristic penetrating and most powerful odour; its specific gravity is 0·939; it remains fluid at −13° C.; and its reaction is neutral. The vapour is highly inflammable and burns with a luminous flame, giving off sulphur dioxide. It is readily soluble in alcohol, ether, and chloroform. A 50 per cent. solution of sodium or potassium hydroxide dissolves the fluid partially, the odour almost disappearing, but returning on the

Digitized by Google

addition of sulphuric acid. Its reactions justify the assumption that one or more mercaptans or thio-alcohols are present. It contains about 30 per cent. of sulphur. Experiment showed that when so far diluted that the air inhaled only contained $\frac{1}{50000000}$ in each cubic centimetre it was still perceptible to the smell. It is a powerful anæsthetic. When inhaled without the admixture of a large amount of air the victim loses consciousness, the temperature falls, the pulse slackens, and if the inhalation were prolonged fatal results would probably ensue. Introduced into the conjunctival sac it produces intense pain and sets up acute inflammation. The fumes of this liquid are overpoweringly pungent and extremely irritating to the glottis.

MEDICAL CERTIFICATES AND BOARD SCHOOLS.

IN another column will be found a letter referring to the case of the West Ham School Board and Mr. R. B. Hunt upon which we commented in our issue of May 30th. We are glad to be able to congratulate the chairman of the West Ham School Board upon his eminently sensible remarks, only we would point out to him that not only have school boards no right to demand the nature of a child's illness, but also no right to demand a certificate at all. We have been fighting this and kindred matters with the London School Board for over a year, and we trust that body will issue a pronouncement to enthusiastic divisional superintendents on the subject, and will ponder well the remarks of the chairman at West Ham.

THE CHEMISTRY OF WHISKY.

THE commonly prevailing ideas as to the chemistry of whisky are evidently confused. The public notion has always been that crude or freshly distilled whisky was injurious and that it required the mellowing influence of age to make it fit for consumption. In other words, new whisky was held to be deleterious because it contained fusel oil, and that the reason why old whisky was more wholesome was because this fusel oil changed in course of time to the so-called œnanthic ether. To put it chemically, the amyl alcohol (fusel oil) oxidises slowly into amyl ether, which is not only thought to be innocuous but to improve the flavour. The Deputy Principal of the Inland Revenue Branch of the Government Laboratory would remove these notions at one sweep. Thus, in reply to a question before the Liquor Commission on Tuesday last he stated—and it was a repeated statement—that it was a mistake to suppose that new spirits contained more fusel oil and were more unwholesome than old. With the former part of his statement we will not now deal, but to the latter we distinctly demur. It cannot be supposed that whisky merchants take the trouble to store their whisky for years unless they know that it is thereby improved from the dietetic point of view. Again, it is well known that so convinced are the authorities of the Canadian Government of the unwholesomeness of new whisky that we believe they have a regulation in force prohibiting the sale of whisky that has not been stored for a certain number of years. Fusel oil is admittedly injurious—indeed, poisonous—according, at least, to the experiments of several observers. In one case, for example, 1 part of amyl alcohol in 500 parts of water caused anæsthesia in frogs in twenty minutes, the heart's action becoming slower, the skin dark, death occurring in about two hours, and the cardiac pulsations gradually ceasing. The common effect of fusel oil is to produce intense headache, and it must be borne in mind that in the case of whisky the action of alcohol must be added to that of the fusel oil. The amount of fusel oil, we believe, in whisky averages about 0·2 per cent. These observations hardly bear out the statements made before the Commission. Incidentally we may add that it is exceedingly satisfactory to find that the consensus of opinion of the witnesses before this Commission appears to be that there is an undoubted decrease in drunkenness in the metropolis, but this decrease, it is noteworthy, is less among women than among men.

SHORTHAND IN MEDICINE.

THE Oxford Shorthand Society has memorialised the General Medical Council, through the Education Committee, to grant the prayer of the Society of Medical Phonographers and include shorthand in the syllabus of the preliminary examinations for medical students, but to decline to in any way favour any one system of shorthand to the detriment of others, such a course being, in the society's opinion, equally opposed to shorthand progress and the public interest, and calculated, moreover, to defeat the primary object of the Society of Medical Phonographers. The memorial is influentially backed by a large number of headmasters and others.

THE LONDON WATER-SUPPLY.

THE hybrid committee appointed to consider the London water companies Bills dealt on Tuesday last with some of the most important measures concerned—viz., the Staines Reservoir, the Grand Junction, and the New River Water Companies. The decision was announced by Sir J. Pease, who stated that the Bills would be passed after the elimination and alteration of certain clauses. The committee were not prepared to grant power for additional lands irrespectively of those necessary for the construction, supply, and discharge of reservoirs. Exception was taken, and we think very rightly, to the deficiency in storage in the case of the Grand Junction Company, and it was felt that this company should be required to give an undertaking that a specified proportion of water run into their filter beds should be for storage purposes. A limit of 80,000,000 gallons per diem was placed on removal from the Thames, and the power to forward water down the conduit must likewise be limited to 30,000,000 gallons per diem on the average of any one month. Mr. Pope, in opening the case for the New River Company, stated that six new wells and three new reservoirs would be constructed, raising the present supply of 46,500,000 gallons to 60,000,000 gallons, or nearly 10,000,000 gallons in excess of the quantity requisite in ten years' time. The committee adjourned till Friday.

THE MIDDLESEX HOSPITAL.

THE inauguration of the new convalescent home at Clacton-on-Sea, which has been founded in connexion with the Middlesex Hospital, is to be celebrated by a *fête* in the hospital garden and medical school on Wednesday, July 1st. The afternoon *fête*, from 5 to 7 P.M., will be graced by the presence of their Royal Highnesses the Duke and Duchess of York, and in the evening the gardens will be illuminated. The members of the *fête* committee, of whom the Marquis of Breadalbane is chairman, have drawn up an excellent programme for the entertainment of the visitors. The musical arrangements are under the direction of Mr. Wilhelm Ganz, and several well-known artistes have offered their services. It is hoped that the result of the *fête* will go far to meet the heavy outlay occasioned by the building of the convalescent home, the maintenance of which will be chiefly met by the munificent bequest of the late Mr. Henry Spicer to the Samaritan Fund. We hope to publish next week a

Digitized by Google

full description of the new building, of which the architect is Mr. Keith D. Young. It is interesting to note that last year the Middlesex Hospital completed the 150th year of its existence which commenced originally in Windmill-street, the present building being erected a few years later in "Marybone Fields," where the foundation stone was laid by the Earl of Northumberland, first president of the hospital. The hospital, therefore, came into existence about twenty years after Guy's foundation, and is coeval with the London Hospital in the east and St. George's Hospital in the west.

TECHNICAL EDUCATION AND HEALTH.

"TECHNICAL Education: a National Necessity,"[1] a paper read before the Cork Young Men's Society last year by Professor Corby, M.D., has now been printed in pamphlet form, and we heartily commend its perusal, for the author possesses a thorough grasp of his subject. England is far behind continental countries in the matter of technical education, and we hope the lecture will receive the attention which it deserves by those who have at heart not only the commercial prosperity of the country, but the welfare of the rising generation. One suggestion which Professor Corby throws out is worthy of consideration apart from its technical aspect, for it would have an important bearing upon health. "Plots of ground," says the author, "should be attached to every national school in the country on which the teacher could give his students practical instruction in agriculture." This of course applies to Ireland, but we think that with certain modifications the idea would be beneficial to other parts of the British Isles.

THE DANGERS OF STREET MUSIC.

WE have frequently animadverted upon the undoubted nuisance occasioned by the itinerant grinding of street organs. This time we have a very serious complaint to make against their use when coupled with the assistance of a dancing troupe. This mode of employing piano-organs to attract public notice is largely on the increase. We protest against this modified form of music-hall performance in our public highways because, as we ourselves have witnessed, it may give rise to very great danger to the passers-by. What might have been a very serious occurrence of this kind happened in Garrick-street this week and we quote it as a case in point. A troupe of four, including a girl gaudily and gaily dressed in brilliant colours, were dancing somewhat wildly to the jaunty airs of a piano-organ. A large crowd lined both sides of this busy street to witness the performance. At length it was the girl's turn to dance alone, which she did effectively enough and evidently to the spectators' delight. After her gyrations had proceeded for a time a hansom cab came along, the horse of which immediately shied on seeing the gestures of the brilliantly coloured dancer. Careering over to the opposite side, which was the wrong side that should be taken in the direction the vehicle was going, the wheels came into contact and interlocked with the wheels of another cab waiting for a fare, with the result that the former, after dragging the latter some distance along, was eventually completely overturned. The crowd was panic-stricken and ran in all directions. The occupant of the cab luckily escaped with slight contusions and some cuts from broken glass, for which he was treated at Charing-cross Hospital. We should like to know whether the police are blind to the dangers of such a show, and if not, why they allow it to go on. We trust that the authorities at Scotland Yard will not fail to take notice of this matter and exercise an increased vigilance in this direction. The possibilities of risk to life and limb through an occurrence of the kind we have described are, it is evident, extremely great, and afford one more argument to spur the Government to the passing of Mr. Jacoby's Bill.

[1] Published by J. Mahony, Cook-street, Cork, price 3d.

A JOINT ISOLATION HOSPITAL AT EAST GRINSTEAD.

AFTER having acquired a site and waited long months in default of any agreement as to terms, a settlement between the East Grinstead (Sussex) urban and rural district councils seems likely to be reached with respect to a much-needed isolation hospital. Each council has decided and made initial arrangements to erect a hospital actually on the same site for its own district respectively, but this anomaly was too startling and it is hoped will be obviated. At a meeting of the urban council it has been decided to appoint a joint sub-committee to carry out arrangements under the following suggestions—viz.: (1) that a joint hospital board be formed on the terms usual in such cases; or (2) that the urban council build two wards of four beds each, and also the larger administrative block, laundry, and mortuary, sufficient to serve both hospitals, in accordance with the sanction of the Local Government Board; that the rural council build two exactly similar wards on their land; and that the urban council manage the hospitals, the rural council to pay half the annual expenses of maintenance and management in addition to the sum of £50 per year as rent for the share of the use of the buildings erected by the urban council. Finally it is suggested that each authority should pay the expenses of their own patients while in hospital. The matter has been so long delayed that it is to be hoped a settlement may soon be arrived at on equitable terms, which should not be hard to arrange.

HOSPITALS AND THEIR MANAGEMENT.

A CORRESPONDENT who signs himself "A Suffering Working Man" complains, through the medium of an evening contemporary, that he has been unable to obtain admission into four London hospitals, three of which refused him on the grounds that there were no vacant beds and a fourth because the case was not a suitable one. On the strength of this he wants to know what becomes of the enormous sums which are raised for the benefit of these institutions, and he further hears, "on good authority, that the staff of these institutions live in ease and luxury on the money which is given by the generous public, whilst the welfare of the patients is a secondary consideration." A more silly letter than this can scarcely be imagined, showing, as it does, a deplorable ignorance of the most elementary facts of hospital management. Anyone who takes the trouble may easily find out that the reply that there are no vacant beds is only too true, not because the staff are rolling in luxury, but because every possible nook and corner is full of patients, and if in some hospitals valuable space is lying idle it is only because sufficient funds are not available to use it. Then, again, this impetuous correspondent seems to forget that hospitals are managed by a board of gentlemen selected from the public. These boards control and check all salaries and hospital accounts and frame the rules of the hospital, and, as far as we know—and we have it also on "very good authority"—while managing fairly, they are the last people to encourage their staff to live in ease and luxury. It is a pity that any paper should insert such absurd views as these; it seems to us better to risk hurting the feelings of "a constant reader" rather than let such nonsense appear in print. It is so easy to generalise an accusation. Let this suffering correspondent name the institutions and the individuals who are thus using public

Digitized by Google

money to their own advantage and only looking upon the patients as secondary considerations. If he can prove the truth of this allegation against any institution he will be doing a beneficial act to the public and medical profession alike; if he cannot do this he will show less ignorance of the subject by keeping silence.

THE DIRECT REPRESENTATION OF THE PROFESSION AND THE LANCASHIRE AND CHESHIRE BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

THE Lancashire and Cheshire Branch of the British Medical Association, as will be seen in our correspondence columns, nominated at their meeting on Wednesday at Southport the following gentlemen: Dr. Glover, Dr. Sam Woodcock, J.P., of Manchester, President-elect of the Lancashire and Cheshire Branch of the British Medical Association, member of the Council and of the Parliamentary Bills Committee of the British Medical Association, and President (re-elected) of the Manchester Medico-Ethical Association; and Dr. Lovell Drage, of Hatfield and St. Albans. Dr. Drage was a distinguished student at Oxford and house surgeon and midwifery assistant at St. Bartholomew's Hospital, and is the writer of several letters on medical politics.

"UNEVENTFUL MIDWIFERY."

IT is always a pleasant duty to us as medical journalists to have to review the work of a general practitioner, hard in its character and extending over a good series of years, especially when the results are satisfactory and the practitioner himself survives in comparative youth and strength. Last week we published the report of the proceedings of the Islington Medical Society, which included an account of his midwifery work by Mr. Jago, under the happy heading "Uneventful Midwifery." We wonder what those who consider medical practice an easy matter would think of the facts so succinctly told by Mr. Jago and of the attendance on over 4700 cases in twenty-three years, not as a sole occupation, but as one of the multifarious duties of a general practice in a populous and not over rich neighbourhood. The number gives an average of about 204 cases a year, and in most of the years doubtless a much larger number. The record and the results are such as any practitioner may be congratulated on. Take the most important point of all—that of mortality. There is nothing more pathetic than the death of women owing to the function of childbirth, and no medical man is worthy of his profession who does not take every pains and make every sacrifice to avert such a result of parturition. Mr. Jago has obviously taken such pains. We have all heard, indeed, of obstetric practitioners who never had any mortality. They never lost a case. But we have rarely known such. We prefer such possible records as Mr. Jago's—excluding two cases of advanced phthisis—a mortality of 7 in 4700 cases, or 1 death in about 671: two cases of death from hæmorrhage, 1 from embolism, 1 from privation, and 3 from septic infection. There is possibly an element of luck in obstetric as in other practice. But it is the business of the accoucheur to control the process of labour and to counteract the element of ill-luck, and this he must chiefly do by early detection of complications and untoward accidents and their early correction, and by the exclusion of all uncleanliness and infection. The element of luck or chance is illustrated by one very remarkable fact in the series of cases now under notice. The complication of shoulder presentation only occurred once to Mr. Jago, and in that case he was sent for by a midwife, who was trying to deliver by pulling upon the arm. It is surely very rare for a practitioner of such large experience to have seen so little of cross presentations. An almost equally strong illustration of the element of luck in midwifery is to be found in the fact that Mr. Jago in his 4700 cases only remembered one case of prolapsed funis. Churchill collected 98,512 cases of labour in which this accident occurred 401 times, or once in 245·5 cases. Mr. Bland, quoted by Dr. Lusk, met with it once in 1897 cases. Allowing for the fact that Mr. Jago has not kept elaborate statistics, which would be almost impossible in such circumstances, and that he may have encountered two or three more of these abnormalities than he can remember, it is still remarkable that he has encountered them so seldom as he has done. We may say the same of his cases of placenta prævia and of the need to perforate, which occurred only once.

DR. KLEIN, F.R.S. will continue on Wednesdays, July 1st and 8th, at 4 P.M., at King's College, Strand, at the instance of the British Institute of Public Health, the Harben Lectures, having as their subject "Recent Researches in the Identification of the Typhoid Bacillus and the Cholera Vibrio." All who may be interested are invited to attend. The first lecture on the subject was given on Wednesday last, but notice of its impending delivery was not sent to us.

THE annual dinner of the Cambridge Medical Graduates' Club will be held at Limmer's Hotel, Conduit-street, W., on July 2nd, the first day of the Inter-University cricket match, at 8 P.M. Dr. W. H. Dickinson, the senior Vice-President, will be in the chair. The annual general meeting for election of officers and other business will be held at 7.30 P.M. Each member may bring two guests; tickets 10*s.* 6*d.*, exclusive of wine.

THE DUCHESS OF CONNAUGHT, who was accompanied by the Duke of Connaught, opened at Queen's Hall, Langham-place, on Tuesday afternoon, a rose *fête* and bazaar in aid of the North-Eastern Hospital for Children, Hackney-road, Shoreditch.

THE Colonial Office has learned by telegram from the Governor of Hong-Kong that there were twenty-one fresh cases of bubonic plague in the week ending June 23rd, and twenty deaths from the plague during the same period.

THE PRINCESS OF WALES, accompanied by the Princesses Victoria and Maud, paid a visit to St. Mary's Hospital on Tuesday last. They were conducted through the wards by Sir William Broadbent.

DR. D. J. GALLOWA has been granted the royal licence to wear the insignia of the Order of the Crown of Johore of the Second Class conferred upon him by the Sultan of Johore.

THE PRINCE OF WALES has signalled his Derby victory by forwarding a donation of fifty guineas to the honorary secretary of the Epsom and Ewell Cottage Hospital.

THE DUCHESS OF YORK will open a "Princess May's Ward for Children" at the Royal Hospital, Richmond, on Wednesday, July 8th.

WE congratulate Dr. Longstaff, L.C.C., upon being alive and sympathise with him on the death of his relative.

THOMAS WAKLEY,

THE FOUNDER OF "THE LANCET."

A BIOGRAPHY.[1]

CHAPTER XXV.

The First Ten Years of THE LANCET: *A Recapitulation.—A few Details of Private Life.—The Kindness of Mr. Goodchild.—The Move to Bedford-square.—Wakley resolves to Contest the Borough of Finsbury.*

IT may be remembered that, for the present, consideration of the doings of THE LANCET was to be restricted to the events of the first ten years of its existence.[2] During these ten years the paper passed from obscurity to notoriety and thence to wide-spread recognition as the organ of the medical profession. With the series of drawn skirmishes between the College of Surgeons and Wakley which was enumerated in the preceding chapter this first decade comes to a rather abrupt conclusion; but before passing to the next phase in Wakley's career—that of Parliamentary life—it will not be amiss to recapitulate briefly the actual outcome of his stormy ten years in occupation of the editorial chair.

THE LANCET was started in the interests of the profession at large inclusive of the students, and was designed to show that the great hospitals of the metropolis were managed to the advantage of a few rather than of the community, and that medical men as a body were wronged by their leaders. The establishment by the action at law with Abernethy of the right of THE LANCET to publish the lectures delivered to hospital classes was much more than the solution of an undecided question in copyright. The privileges of copyright would have prevented, and actually did prevent, Wakley from printing the lectures. But when he proved the lectures to have been delivered in a public capacity he gained his point, and in doing so damaged the unearned prestige of many eminent teachers and got his journalistic foot for the first time into those fastnesses of privacy—the metropolitan hospitals.

The articles against malpraxis among hospital surgeons immediately followed and reached their climax in the sensational case of Bransby Cooper *v.* Wakley. They did good and harm. They roused a wholesome distrust in the minds of the profession of the system under which such mishaps were possible. They sounded a revolt against a nepotism that nowadays seems too monstrous to have existed, but which appeared seventy years ago to be natural and void of reproach. They stirred up in the minds of the profession at large a determination to be better treated and only to be ruled by those who were worthy to rule them. All this was effected by Wakley, and almost immediately a purer and better state of things was brought about within our hospital walls. The harm that these articles did was much less than the good, but must not be overlooked. The public dissemination in THE LANCET of such bitter criticism on lecturers, surgeons, and administrators in the well-known hospitals of London brought the profession of medicine into public and unequivocal disrepute. THE LANCET speedily became a purely medical journal, but others besides medical men read it, and learned with some shattering of their idols that the great Abernethy desired not to give his students fair measure in return for fees, that the great Cooper considered the indispensable qualifications for an appointment at Guy's Hospital were relationship or apprenticeship to himself, and, finally, that a medical staff selected in accordance with these principles, not only at Guy's Hospital, but at all the metropolitan hospitals, more than occasionally failed to attain to the high standard of skill and knowledge that was to be expected of them and with which they were generally credited. A second disadvantage to the profession that followed on Wakley's revelation of hospital mismanagement was the stirring up of bad blood. Some men were for Wakley and some were against, but his excessively plain speaking and downright methods of conducting a dispute made it imperative that those who were on his side should quarrel outright with those who were not.

From reviewing and criticising the administration of the hospitals Wakley passed natually to the consideration of the corporation which granted the diploma most sought after by the students. This, the Royal College of Surgeons of England, was officered by the very hospital surgeons whose scientific methods left in Wakley's opinion so much to seek. The Council of the College were hospital surgeons wholly or in large majority. They were chosen for life and nominated their own successors. They selected examiners from among themselves and took no certificates save from hospital surgeons. Here THE LANCET did solid good even in the first ten years of its existence, but this phase of Wakley's work suffers a little from being told piece-meal in accordance with a time limit. The first ten years of THE LANCET saw the end of its Editor's principal legal quarrels. They witnessed his distinct victory over the narrower and more jealous of those responsible for hospital management, and during their passage he collected round him a staff of ardent and able writers capable of maintaining his journal in the position to which he had brought it, capable of carrying out his schemes for the breaking down of monopolies and furthering the cause of the profession at large. But his determination to bring about reform in the College of Surgeons, although in no wit abated, and although not even at this early stage of the struggle fruitless of result, had not at the end of the first ten years reached any definite stage of success. Wakley had roused a wide-spread feeling among the Members against their Council; he had exposed the unsoundness of the constitution of the College; he had criticised certain of the by-laws in such a way as to ensure their repeal; he had summoned the first public meetings ever held by the Members, and had dominated those meetings; he had placed the College on its defence, and had elicited from the Council a poor refutation of the charges brought against them; he had organised a petition to Parliament for State assistance in his schemes for reform; and he had come into personal conflict with the Council in an attempt to assert on behalf of the Members a right to meet in the theatre of their College to discuss matters of professional interest. All these things he had accomplished, but at the end of ten years the position of the Members was not appreciably improved. The reform party had been chilled by their slow advance and by the loss of the help of Mr. William Lawrence; the petition to Parliament had ended in nothing, and the concessions made by the Council to the Members amounted to but little more. An extension of the time from the ten years which are under consideration to twenty years would show that the seed sown was to result in a fair harvest; but to deal more diffusely at this period with Wakley's career as a journalist would be to trespass upon space which must be allocated to other phases of his life. The discontinuance of the story of his relations with the College of Surgeons seems abrupt, but this cannot be avoided.

Wakley's public career has bulked so largely that almost nothing has been said of his private life. Nor is there very much to say. The rise of THE LANCET from a

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., XVI., XVII., XVIII., XIX., XX., XXI., XXII., XXIII., and XXIV. were published in THE LANCET, Jan. 4th, 11th, 18th, and 25th, Feb. 1st, 8th, 15th, 22nd, and 29th, March 7th, 14th, 21st, and 28th, April 4th, 11th, 18th, and 25th, May 2nd, 16th, 23rd, 30th, June 6th, 13th, and 20th respectively.

[2] See Chapter IX. of this Biography.

Digitized by Google

young man's journalistic venture to an assured and serious success was, it need hardly be said, accompanied by a commensurate rise in the private fortunes of the Editor. These when they were last the subject of mention[3] were, it may be remembered, at a low ebb. The disastrous fire had consumed his goods, which were not insured to their full worth, and the Hope Fire Assurance Company, by resisting his claim for compensation, had kept him out of his money until his practice was ruined. The fire cost him £1600 and a practice of £700 per annum, for which a large sum in ready money had been paid. He received in compensation all that he could legally claim—viz., £1200, and was unable to make up his mind how to use this sum to the best advantage. His father-in-law looked askance upon him, not desiring to support his daughter's husband, yet thinking that the possibility of his having to do so was far from remote. The ready-money practice that he purchased in Norfolk-street, Strand, did not give him congenial occupation, and, much as his wife loved her husband, she did not conceal from him that she had a cordial dislike of his profession. She was also aware that her wealthy parents desired for her a fitter environment than was afforded by Norfolk-street. She had now two children, Thomas and Elizabeth, who were respectively six and five years old, and for their sakes as much as for her own she wished to reside in a pleasanter and more suitable neighbourhood.

This was the state of their domestic affairs when THE LANCET was first published, but the paper proved almost immediately a pecuniary success. The circulation was shown in one of the earlier libel actions to be 3000, and this was considerably increased by the Editor's attitude towards the College of Surgeons.

From a journalistic point of view his resolute stand against corruption in that body was his greatest coup, as it was the most important achievement of his life. The other successes of THE LANCET were smaller and more personal. However earnestly Wakley might plead that his actions and counter-actions at law had all been undertaken in defence of the broad principles of reform, a certain proportion of his readers would be unable to see how their interests were advanced by his pugnacious tactics. They might hope that he would win in the magnanimous way that outsiders generally desire victory to go to a gallant fighter against odds, but it was more or less as outsiders that they had watched the contests. Now the attack on the College of Surgeons was so clearly made in the interests of the profession at large that the feeling of being merely interested as spectators disappeared from the mind of his readers and was replaced by a very definite and properly selfish partizanship. In his crusade against the College Wakley was obviously fighting the battle of all the medical men in the kingdom save a few privileged persons, and his list of subscribers at once increased rapidly, while his own position rose from that of a journalist who catered capably to the wants of his public, and now and again furnished them with a thoroughly enjoyable sensation, to that of a leader of a liberal movement attended from the first with success and promising greater things in the future. Upon the more general recognition of Wakley as a single-minded reformer followed a vast improvement in the position of his paper. It gained in power and importance, its opinion had to be reckoned with, while its intolerance and scurrility—the occasional presence of which cannot be denied—were seen not to be its essentialities.

One of the first persons to recognise the great position that Wakley was securing for himself and his paper was Mr. Goodchild, his father-in-law. The very business qualities in that gentleman which had led him to bitterly resent the failure that had attended Wakley's fortunes consequent on the Argyll-street outrages made him prompt to recognise the quick passage of his son-in-law from unmerited discredit to a position of influence and responsibility that was rapidly passing to one of power. The instinct of the successful commercial man warned him that in THE LANCET Wakley had a great property, and that the shrewdness, humour, and force that were displayed in the editing must secure him a prominent public career. He was, moreover, casting about for a fitting opportunity to come to the succour of his daughter, and the rising position of THE LANCET, together with the storminess of its career, afforded him an excellent one. It would be generous to help, and it would not be foolish, so he approached his son-in-law and offered to assist him in his literary venture. This timely aid completely turned the scale of fortune in Wakley's favour. As soon as circumstances warranted his doing so he gave up the house in Norfolk-street and took a larger one in the pleasanter neighbourhood of Thistle-grove, which had the attraction for himself, his wife, and children of possessing a large garden. Thistle-grove was then almost a country lane, but now it is a street called Drayton-gardens, in the heart of that thickly populated part of Brompton and Chelsea that delights to disguise itself under the name of South Kensington, though it still preserves many of the features of suburban villadom. Here his two younger children — Henry and James — were born, and here he stayed until 1828, when he moved into No. 35, Bedford-square, the house which is associated with all his public life as Member of Parliament for Finsbury and coroner for Middlesex.

The neighbourhood of his new address was chosen for a very definite purpose, and one which was approved of by Mr. Goodchild in a practical manner—which means to say that he helped Wakley to find the necessary money to make so important an alteration in his domestic affairs. Wakley's intention now was to offer himself as political candidate for the borough of Finsbury, and Bedford-square was fortunately situated for the purpose, being near the office of THE LANCET, situated at this time in Essex-street, Strand, and also on the edge of the enormous Parliamentary district which he aspired to represent. Immediately upon his establishment in his house he set about using it in accordance with his designs. An open-handed, cheery, and humorous man he delighted in good company, and it must not be supposed that all the profuse hospitality which at once became the rule in the domestic management of 35, Bedford-square was the outcome of a design upon the minds of his possible electors. But while he revelled in the entertainment of his friends he was assiduous in the reception of his political allies, medical and lay. At his fortnightly gatherings for whist or chess he gathered round him a large number of staunch friends who were attracted by his eloquence, his audacious defence of popular rights, his determination, self-confidence, and kindliness of manner. And most of his guests believed in him and prophesied for him a speedy success in the political world, thereby confirming him in his intention and endorsing the opinion of his once angry father-in-law.

(To be continued.)

[3] Chapter VII., Feb. 15th, 1896.

LITERARY INTELLIGENCE.—Amongst Mr. H. K. Lewis's announcements are new work by Dr. E. W. Goodall and Dr. J. W. Washbourn, "A Manual of Infectious Diseases," and a fourth edition of Professor Crookshank's "Bacteriology," which is virtually a new work, having been entirely re-written, as its title, "A Text-book of Bacteriology, including the Etiology and Prevention of Infective Diseases, and an Account of Yeasts and Moulds, Hæmatozoa, and Psorosperms" shows. Also "Notes on the More Common Diseases of the Eye," by R. W. Doyne, F.R.C.S.Eng., and "Disease and Defective Sanitary Arrangements," by W. H. Corfield, M.D.Oxon.

METROPOLITAN HOSPITAL SUNDAY FUND.

WE continue below our record of some of the principal amounts received at the Mansion House, the lists of which have been received at THE LANCET Office, up to the time of our going to press on Thursday, when the total sum received amounted to nearly £31,500. At the corresponding period last year the total was £31,000 :—

	£	s.	d.
Trinity Presbyterian Church, Notting-hill	44	3	1
St. Gabriel, Warwick-square	57	19	9
St. Philip's, Sydenham	31	17	6
St. Paul's, Canonbury	45	0	7
St. Mary's, Shortlands	48	1	0
St. Saviour's, Paddington	99	7	5
Marylebone Presbyterian Church	65	17	2
St. Augustine's, Queens-gate	83	19	0
Gray's Inn Chapel	53	14	3
Wanstead Churches	44	2	1
Bromley, Kent, Parish Church	84	4	2
Hammersmith Parish Church	30	1	0
Hampstead Parish Church	74	0	6
St. Pancras Parish Church	55	6	5
Beckenham Parish Church	69	18	9
Chipping Barnet Parish Church	39	6	4
All Saints', Hatcham Park	56	9	0
Mr. Julian, senior	21	0	0
Box outside Mansion House	27	18	3
St. Mary's, Boltons (with additions)	90	0	0
St. Matthew's, Denmark-hill	91	11	4
St. Andrew's, Stoke Newington	85	11	4
All Saints', Clapham-park	70	0	0
St. James's, Hatcham	80	0	0
St. Mary Magdalene, Peckham	36	5	3
St. David's, West Holloway	20	10	5
Christ Church, Southgate	41	5	6
Church of the Annunciation, Chislehurst	88	10	4
St. Mary's, Spring Grove	28	9	2
Nutley-lane Church, Reigate	28	0	0
St. Paul's, Finchley	46	16	6

THE NEW INFANTRY SWORD EXERCISE.

As we have already announced,[1] during the progress of the Military Tournament some members of the profession in London interested in fencing visited the Agricultural Hall, Islington, at the invitation of Colonel Malcolm Fox, Inspector of Gymnastics, for the purpose of examining into the practice and theory of the new infantry sword exercise (1895). This exercise is that of Il Cavaliere Ferdinando Masiello, the Florentine *maître d'armes*, and the system was first introduced into this country in 1893. Since that period its followers claim to have carried all before them in the various tournaments held throughout the country.

Colonel Fox explained the main points of this system to those present and illustrated his remarks practically upon Sergeant-Major Palmer, Army Gymnastic Staff. This warrant officer afterwards gave a series of lessons, both simple and advanced, to various non-commissioned officers who had been victorious in this year's tournament. The pupil taking the lesson was, in the majority of cases, stripped, so that the muscular actions involved were easily demonstrated. The main differences between this and other systems were shown to consist in: 1. The grip of the sword, in which the whole hand is used as a claw, thus securing the maximum degree of prehensile force. The thumb is placed along the back of the handle and serves to accurately direct the point. If a penknife be taken in the hand to cut a point to a pencil the fingers and thumb instinctively take the Masiello sword-grip. 2. Circling cuts, which are a series of exercises in "cutting" that tend to develop in the highest degree power over the weapon; and enormous force can be put into these cuts, since the hinge-joint of the elbow is the centre of a circle of which the distance from the elbow to the point of the sword is the radius, for in this system the wrist-joint is never allowed to move except in the action of adduction—at the finish of the delivery of a cut. The wrist, being a universal joint, is capable of any form of error in making a cut; whereas the elbow-joint, having one motion only, cannot possibly deflect the edge from its objective. Consequently a cut made in accordance with Masiello's system cannot be delivered otherwise than with the edge leading. 3. Parries. These are all, except the fourth, made with the arm straight on the completion of the formation of the parry, and with the point on, or almost on, the adversary's body. In many cases the formation of a parry is at the same time a "riposte," and the value of this will be obvious to any practical swordsman. In passing from one parry to another the arm is very slightly bent, thereby gaining a forward motion when meeting the adversary's blade that greatly adds to the power of the defence. Nor can the shock of the adversary's attack be ever met at a right angle as in the old method, consequently the blow loses five-fifths of its force, since it runs along the blade down to the hilt instead of being received on one single point of the blade. 4. The position of "on guard." This is wider than of old, the distance between the heels being about two and a half soles' length, according to the length of a man's thigh, instead of two soles' length as hitherto. This increased distance gives a much firmer base with a greatly increased facility for rapidly advancing towards or retiring from an opponent. 5. The lunge. In this system the body is inclined as far forward as possible when lunging; thus a gain of about twelve inches in actual reach is obtained, and the recovery to the position of "on guard" is rendered much easier than in the old method, where the body was kept upright for obvious anatomical reasons that have already been explained in THE LANCET.[2] 6. The jump. This is an action somewhat difficult to explain but very easy to perform. It is a rapid means of getting to the rear out of reach of an opponent. It is an action peculiar to this system, and consists in pressing strongly off the right foot, carrying it to the rear, and at the same time carrying the left foot an equal distance to the rear, so that when the feet are again on the ground the correct position of "on guard" is assumed.

The above were the chief points touched upon, and then an interesting series of lessons with sword and foil were gone through. In conclusion Colonel Fox drew attention to Masiello's series of corrective exercises with the sword, exercises designed to prevent any tendency to spinal curvature that might be induced by constant lunging. He also drew attention to the fact that a military system of swordsmanship must have for its object the defence of a man's life and his power to disable his adversary. He claimed for Masiello's system that it fulfilled these conditions.

Some staff-sergeants of the gymnastic staff were then shown and were seen to be men of admirable physical development. Sandow's system of "Light Dumb-bell Exercises" was demonstrated, also a few exercises without apparatus.

At the conclusion of the display Sir William MacCormac cordially thanked Colonel Fox for the opportunity he had afforded him and his colleagues of examining into the new system of swordsmanship—a system that appeared to be thoroughly sound, both practically and theoretically.

Among those present were the following members of the medical profession:—Mr. W. H. Bennett, Dr. Champneys, Mr. Clinton Dent, Dr. J. H. Drysdale. Mr. Muirhead Little, Sir William MacCormac, Mr. Howard Marsh, Mr. J. H. Morgan, Mr. W. H. Staveley, Dr. Frederick Taylor, Mr. J. H. Waring, and Dr. Dawson Williams.

CHOLERA IN EGYPT.

"NEVER since 1865—not even during the memorable summer of 1883—has Egypt been afflicted with such a terrible outbreak of cholera as she is now experiencing. It is generally accepted (though denied by the doctors) that the disease is endemic in the country in a more or less inconspicuous way."

Our readers who may not have seen the original will doubtless be surprised to learn that the above sensational statement is taken from the usually well-informed *Pall Mall Gazette*. It is, of course, possible that the present outbreak of cholera in Egypt may increase in severity, and that eventually it may prove more destructive than its precursors, but up to the time of writing nothing has occurred to justify the grave note of alarm sounded by our contemporary. On the contrary, the epidemic has so far shown itself amenable to control and from the latest returns it appears that the number of cases is decreasing both in Cairo and at Alexandria. A certain amount of panic did, and probably does still, exist, for cholera and panic are notoriously inseparable; but if the homeward-bound steamers are filled to overflowing, it must be remembered that this is the season of the year when the usual exodus takes place on account of the summer heats. The inhabitants of Egypt, foreigners as well as natives, have every reason to repose the fullest confidence in the zeal and energy of their sanitary guardians, but unfortunately these officials are beset and hindered in many ways. They are expected to make headway against a deadly foe, but the weapons supplied to them for the combat can only be described as totally inadequate.

Cholera at Cairo and Alexandria is steadily declining, but the disease seems to be slowly extending in the provinces. The number of deaths reported on the 19th instant was 10 at Cairo and 3 at Alexandria. Elsewhere there were 189 fresh cases and 170 deaths. The total number of cases reported in Egypt since last September is 5193, and of deaths 4776; the mortality rate of those attacked has therefore been very high. According to a Central News telegram an outbreak of cholera had occurred in the 5th Battalion of the Egyptian army, stationed at Korosko. There have been 14 cases returned, with 7 deaths, and the occurrence has naturally given rise to some anxiety lest the disease should spread to the troops engaged in the Soudan campaign. It is, of course, quite possible that it may do so, but we do not think that any grave apprehensions need arise in regard to this. The troops are in the desert, which is the best place for them to be in the event of their being attacked, they are encamped on clean and healthy sites, their water-supply is believed to be good, and all hygienic requirements are carefully attended to. We believe the health of the British troops at Alexandria and Cairo and in the Soudan to be quite satisfactory at the present time.

THE GENERAL MEDICAL COUNCIL AND THE CIVIL RIGHTS DEFENCE COMMITTEE.

THE following letter has been addressed by Mr. Timothy Holmes, as chairman of the Select Committee of Medical Defence in the Civil Rights Association, to Sir Richard Quain, as President of the General Medical Council:—

"5, Mitre-court, Temple, London, E.C., June 20th, 1896.

"SIR,—As Chairman of the Select Committee on Medical Defence I am requested by my Committee, in reference to previous correspondence and especially to the letter of your Business Committee dated June 6th, 1896, and to a letter of your solicitor dated Nov. 25th, 1895, to point out the following errors or misconceptions. The letter of the Business Committee dated June 6th, 1896, quotes the solicitor of the Council as saying that Mr. Anderson's case is wholly outside the functions and powers of the Council. Now this is not what the solicitor said. His reply runs thus: 'It is wholly beyond the province of the Council to take part in an endeavour to obtain for an individual his civil rights, and the fact that the individual claiming them is a medical practitioner does not in any way alter the position.' We do not ask the General Medical Council so far to depart from their functions as to endeavour to defend civil rights generally, but we believe it to be a part not only of their functions, but also of their duty, to defend the professional rights which they have themselves confirmed to Mr. Anderson by their registration, which they would be bound to deprive him of if he were guilty of infamous conduct in a professional respect, and of which they, and they alone, on such grounds alone, have by the Medical Acts the power to deprive him.

My committee desires in this relation to point out that for what is asked there cannot in the nature of things be either authority or precedent; since so remarkable a state of facts could not be anticipated or provided for and has not before occourred. There can, my committee submits, be no obligation, however, on any member of the General Medical Council to continue to issue misleading and illusory certificates of registration holding out on behalf of the Crown promises of rights now by the Crown, acting through the judges, declared to be no rights at all, but to depend on the arbitrary will and pleasure, or even malice, of the judges. It could not be compulsory on any man to hold office under such conditions; but far short of resignation we submit that there is nothing in the Medical Acts to fetter your inclinations; and no conditions either in law or in morality, than can render it improper for you to take corporate action to ascertain that the promises of which you are the channel are not broken to those to whom they are made. This my Committee ventures to submit is not a question of law, but of those natural obligations which are above and beyond expressed law, and of which the law is the more or less imperfect embodiment. The rights to which I here allude are solely those which your Council confirmed to Mr. Anderson.

"My Committee asks of you that a meeting of the executive council be convened and a deputation of this Committee be received by which the case and our views may be fully placed before you, and that this be followed by a special meeting of the Council to consider an interpretation of the law that seriously affects the nature and value of every certificate of registration issued, and gives to every man entering the profession, as well as those who have already been admitted, the right to ask you, 'Have I under this certificate the right to recover reasonable charges for work and services rendered and the right to render or refuse my services? Or can I, for withholding or withdrawing my services be punished by damages, costs, and imprisonment and be arbitrarily and maliciously denied all right to recover reasonable charges for services actually rendered?'

"This is a question in the answer to which we venture to submit that the General Medical Council as a body, and each member of it individually, is so far concerned in honour as that no legal technicality or equivocation can relieve him.

"I have the honour to be, Sir, your obedient servant,

"TIMOTHY HOLMES,

"Chairman of the Select Committee on Medical Defence."

There can be no doubt that Mr. Holmes makes out an excellent case why the Executive Committee of the General Medical Council should receive a deputation from the Civil Rights Defence Committee, and we hope that this letter will receive a favourable answer.

THE HOLIDAY SEASON.

(*Continued from p. 1743.*)

THE tours arranged by Messrs. Thomas Cook and Son and by Messrs. Henry Gaze and Sons, "conducted" and "independent," offer many advantages to the traveller both at home and abroad. The total cost of any particular journey can be accurately estimated, or given a certain sum of money the best possible tour that can be taken for that amount can be readily supplied. In addition to these advantages the tourist has the benefit of interpreters where necessary, and none but the best hotels are recommended; the best routes only are selected and the tours are mapped out in such a way that all the chief points of interest in a given itinerary can be seen in the smallest possible space of time by those whose period of holiday-making is limited. There are many other advantages to which we have not space to refer, but a letter to either of the agents will be promptly attended to and bring forth any information relative to travel the applicant may desire. So "prodigious," as Dominie Sampson would have said, is the amount of printed matter issued by these two firms that we are unable to give even an abridged list of all the tours or combination of tours by either firm, but we may mention a few among the many booklets which can be obtained on application.

THOMAS COOK AND SON.—The Programme of Summer Tours to Various Places of Interest in Great Britain and the Continent at moderate and inclusive charges, combining railway ticket and hotel and other accommodation, contains some capital tours for those whose time is very limited, including Saturday to Monday trips to the seaside and other summer resorts. "Tours in the Emerald Isle" and "Tours in Scotland," both illustrated and containing brief descriptive notes, should prove useful to those who have decided to spend their holidays in either of these portions of the British Isles. Italian Tours, with maps, embrace the chief cities of Italy, with extensions to the Italian lakes, the Island of Sicily, &c., with breaks of journey. Independent Tours in Normandy and Brittany, in Norway, Sweden, and Denmark, Conducted Tours in Norway, Sweden, and Denmark, in Holland and the Dead Cities of the Zuyder Zee, in the Ardennes, in Iceland and the Land of the Midnight Sun, Paris, Switzerland, Normandy and Brittany, Holland, Belgium, the Rhine, and The Black Forest, are the titles of some of the gratuitous pamphlets. Intending visitors to the National and International Exhibitions in Berlin, Geneva, Budapest, Innsbruck, and Kiel should obtain the small books giving the tours arranged in connexion with these places. Those interested in the forthcoming solar eclipse should obtain the special programme of steamer cruises to the Norwegian Fjords, the Mediterranean, West Indies, Canary Islands, Azores, &c. Cook's Excursionist and Home and Foreign Tourist Advertiser is too well known to travellers to need any description from us.

HENRY GAZE AND SONS.—Gaze's Indian Tours, comprising the principal points of interest to tourists in India, Burmah, and Ceylon, should be consulted by those about to visit these parts. Cheap Italian tours are detailed in Gaze's Cheap Italy, and Switzerland, the Rhine, Paris, Brussels, Amsterdam, the Ardennes, &c., are countries and places to which special conducted tours may be made. Of special note are the ten-guinea Swiss tours to Grindelwald and the Bernese Oberland or Davos Platz and the Engadine. A special cruise for the total eclipse of the sun on Aug. 9th, by the ss. *Norse King*, leaving London on July 25th, is announced, and also a special pleasure cruise with the same object by the ss. *Kong Harald*, leaving Newcastle on July 30th. Gaze's Shipping Programme gives lists of sailings by all principal lines of passenger steamers to all parts of the world, pleasure cruises, through overland fares, and advice and rates for emigrants; and the well-known *Tourist Gazette* contains particulars of many cheap and interesting tours, including some cheap week-end excursions.

SHIPPING COMPANIES.

SHAW, SAVILL, AND ALBION COMPANY, 34, Leadenhall-street, E.C.; Glasgow agents: 15, St. Vincent-place, Glasgow.—This Royal Mail Steamship line between London and New Zealand, Tasmania, and Australia issues a handbook of information for passengers with brief notices on the places touched on the outward and homeward journey, which is made in from forty to forty-five days. The book contains all the information the traveller is likely to need. Fares to or from New Zealand range from £68 to £15 15*s*., Australia £72 to £16 16*s*., South Africa from £28 to £8 8*s*., and Teneriffe from £15 to £7. The return fares are as follows:—

Class.	To and from New Zealand or Tasmania.	To and from Australia.	To and from Teneriffe.
	Per adult.	Per adult.	Per adult.
First saloon	£100	£110	£25
Second saloon	65	70	20
Third-class, 2 berth cabin	36	38	16
Third-class, 4 berth cabin	32	34	14
Third-class, open steerage	28	30	12

Digitized by Google

ROYAL MAIL STEAM PACKET COMPANY, 18, Moorgate-street, E.C. — "Tours in the West Indies," issued by this company, is a tastefully printed and illustrated booklet giving details of the various first-class tours arranged by the company. Full information for passengers by the Brazil and River Plate route is given in a small pamphlet. During June, July, and August very pleasant voyages can be made to Brazil and the River Plate, as during that season the weather is comparatively cool. The cost of return tickets to Buenos Ayres is £52 10*s.* and £60, the voyage taking seven weeks, or to Brazil and back £45 or £52 10*s.*, the time occupied on the voyage being five weeks. The vessels on this route are of about 6000 tons, with all the latest improvements of modern ships. During the winter the company organise special trips to the West Indies at the very moderate charge of £65 for sixty-five days.

THE ORIENT STEAM NAVIGATION COMPANY.—The cruises arranged by this company embrace Norway and the North Cape for the Midnight Sun, Lapland for the solar eclipse in August next, Spitzbergen, Copenhagen, Stockholm, St. Petersburg, Moscow, Kiel, the Baltic Canal, and Heligoland. The last-named cruise provides an opportunity of visiting the fair at Nijni Novgorod. In addition to these short trips may be made by the mail steamers of the Orient line to Gibraltar, Naples, and Egypt. Pamphlets giving full particulars can be obtained on application. A pamphlet entitled "Pleasure Cruises to the Land of the Midnight Sun" is compiled in the manner of that excellent book for ocean travellers, "The Orient Line Guide." The following quotation heads one of the chapters in the pamphlet:—"To know what to observe, when and how to look for it, and to be able to recognise it when seen, is one of the most important qualifications of the traveller, and is that wherein intelligent guidance may be of the greatest service." This is the keynote of both the Orient Line Guide and the pamphlet referred to.

ALBION S.S. CO., LIMITED, 4, Lombard-street, Newcastle-upon-Tyne.—"Yachting Cruises in Norway by the Yachting Steamer *Midnight Sun*" is the title of this company's handbook giving the itinerary of the cruises, together with plan of her cabins, showing the prices of the berths from 12 to 25 guineas. Although the cabins differ in prices, chiefly in accordance with their more or less favourable position in the steamer, all passengers (first-class passengers alone are carried) share alike the other privileges of the steamer.

THE PENINSULAR AND ORIENTAL COMPANY.—For India, China, Japan, Australia, Tasmania, and New Zealand the handbooks issued by this company give all necessary information.

MISCELLANEOUS.

The Tourist Guide to the Continent (price 6*d.*), edited by PERCY LINDLEY, is a well-known guide issued by the Great Eastern Railway Company. The cycling routes in Holland, Belgium, and Germany should prove useful to knights of the wheel. Among the new features of the seventeenth annual issue of the Guide is a series of Continental maps and a chapter giving particulars as to the cost of Continental travel.

Summer Tours in Scotland. Price 6*d.* Published at 119, Hope-street, Glasgow.—Those who prefer to spend the best part of their holiday on the water will find ample opportunity for doing so by taking advantage of the excursions arranged by David MacBrayne's Royal Mail steamers *Columba*, *Iona*, &c. Where these steamers go and what is to be seen there the illustrated handbook before us well describes.

On Sea and Shore.—This little book describes a summer holiday ocean trip to the Highlands by the Aberdeen Steam Navigation Company, of Aberdeen Wharf, Limehouse, and 102, Queen Victoria-street. The voyage and the tours through Scotland are chattily described and well illustrated. A useful map accompanies the book.

A Summer Holiday in Holland. By CHANTREY CHURCHILL. Price 6*d.* (H. Grube, 12A, Paternoster-row, and G. Vickers, 1, Angel-court, Strand.)—This is really a guide to Scheveningen, the Dutch Brighton, but it also describes the towns and places of interest which can be easily reached from that popular holiday resort. For the tourist who visits Holland for the first time no more interesting and instructive guide-book could be desired.

The Little Man Island. By HALL CAINE. This charming guide to the Isle of Man can be obtained upon application to the Isle of Man Board of Advertising Office, 27, Imperial buildings, Ludgate-circus, E.C. With the aid of this little book and the *Sailing Arrangements* of the ISLE OF MAN STEAM PACKET COMPANY those in search of a novel and pleasant holiday field should be able to find what they require.

In bringing to a close our notice of the facilities afforded to travellers by the various railway and steamship companies we would point out that the space we have allotted to each individual company is not necessarily a measure of its importance. In some cases we have been supplied with quite a large quantity of holiday literature, while in others we have received only a few handbills.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Enteric Fever at Helmsley, by Dr. BRUCE LOW.[1]—The inquiry as to a prevalence of enteric fever in this small market town, with a population of 1350, at the end of the Vale of Pickering, was made on the request of the local medical officer of health in view of the difficulty experienced in arriving at a cause of the outbreak. There had been no enteric fever in Helmsley for some years, but in August, 1895, no less than 34 attacks took place, and before the end of September there had been 43 cases and 8 deaths. A few other cases occurred in two neighbouring districts, raising the total attacks to 60. The three conditions that had to be thought of in connexion with the origin of this outbreak may be considered separately. One was the influence of insanitary conditions, including deficient sewerage. This is discussed at great length, and it is clear there was much to be found fault with as regards sewerage, house drainage, and privy-middens; but though these may somewhat have favoured the spread of the disease, the unwholesome conditions referred to do not appear to have affected the diffusion in any marked degree, and the only defect that could be looked upon as having had any general or substantial influence on the health of the place was the state of the beck with its accumulation of filth in dry weather. Notably was this the case when after such accumulations a sudden flood spread this filth over the sides of the stream, and the stuff mingled with sand and gravel was used to repair a certain footpath near houses. The water-supply and its alleged pollution had next to be considered. The water comes from a spring about a mile outside the little town, the supply being piped, and supplemented on occasion by other springs. After a connexion had been made with an additional spring some flags had been disturbed, and pollution by human excreta must almost necessarily have occurred. Indeed, there was much in the ultimate distribution of the fever to implicate the water-supply; but by this time a more definite explanation, and one that sufficed better to meet the difficulties involved, had been made out. This third point was the specific contamination of a particular milk-service. Enteric fever in an obscure form was imported into one of the milk-seller's households, and it spread under circumstances that made its diagnosis very uncertain at the time; but there is little doubt that there was community of tending the sick and of milking cows and other dairy operations which can hardly have failed to lead to contamination of the milk. That the milk-supply did become infected must be accepted as proved, and that as a consequence enteric fever was spread amongst the consumers of the milk cannot be open to doubt. Exceptional incidence of the disease was also noticed in the neighbourhood of the dairy whence it is known that a considerable number of persons took their milk-supply. Dr. Porter, the medical officer of health, had already suspected this milk-service, and he arranged that the duties of supplying milk should be forthwith transferred to other hands. Within a fortnight of this the disease came to an end. We have only glanced at a report which, with its plates, &c.,

[1] Eyre and Spottiswoode, East Harding-street, E.C.; John Menzies and Co., Edinburgh and Glasgow; Hodges, Figgis, and Co., Limited, Dublin. 1896. Price 9*d.*

Digitized by Google

covers nearly twenty pages, and which embodies the story of a very careful piece of etiological research; a study of the complete document will be of interest especially to those engaged in the public health service.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Cheltenham Urban Sanitary District.—Dr. J. H. Garrett has had the common lodging-houses of Cheltenham re-measured and re-ticketed during 1895, but he relates that on a night visit of one of the inspectors the by-laws were found in several instances to be flagrantly contravened and that four lodging-house keepers were prosecuted. In commenting upon the need for improved supervision of dairies, cowsheds, and milkshops, Dr. Garrett expresses the opinion that the frequent inspection of the houses and of testing for tuberculosis of the milch cows by a veterinary surgeon is the only procedure likely to materially guard against the sale of tuberculous milk. The corporation have installed electric light in Cheltenham, and this fact, Dr. Garrett observes, affords to owners and occupiers of factories and workshops the opportunity of avoiding the pollution of air by the consumption of gas. The corporation has also, with a view to abolishing private slaughter-houses, applied for a provisional order for the compulsory closure of these places, there being in Cheltenham a good public abattoir. Dr. Garrett, in speaking of the Gloucester small-pox disaster, remarks that this town, by its "anti-vaccination craze," has become a standing danger to every other town around with which it has communication. Considerable additions have been made to the Delancey Fever Hospital during the year under review, and we learn from the annual report of that institution that a new wing for the accommodation of scarlet fever and enteric fever cases was opened in July. Diphtheria is not yet provided for, but it seems that next year the isolation of this disease in the hospital is to be arranged for by the erection of a diphtheria block.

Maidstone Urban Sanitary District.—Mr. M. A. Adams reports that in his district the mean age at death for the year 1895 was 36·95, a rate which exceeds the average of the previous seventeen years by 3·73. The main causes of this excess were, Mr. Adams points out, the relatively few deaths among young children, especially during the second quarter of the year, and the excessive mortality among the very aged during the extremely low temperature of the first quarter. Mr. Adams draws attention to the fact that the cold had apparently no commensurate fatal effect upon infant life, and that, probably owing to the care taken by mothers, infants get through the severe weather well. In dealing with the interesting subject of measles Mr. Adams observes that there would appear to be an increased rather than a diminished tendency towards the prevalence of that disease, a fact which he regards as in all probability due to facilities for infection as afforded by the elementary schools. Certainly there has not gone hand-in-hand with compulsory education a sufficient regard for the control of this dangerous disease. Mr. Adams is apparently not in favour of the notification of measles unless it can be accompanied with *compulsory* hospital isolation, and even in regard to isolation he doubts whether it would be practicable to deal with such young children apart from their parents. We must confess we are not entirely in accord with Mr. Adams on either of these points, and, while fully recognising the difficulty and perhaps impossibility of controlling measles in such a satisfactory fashion as is possible with some other infectious diseases, we think much good might be done by notification even as apart from hospital isolation, more especially in the way of excluding from school the children from infected houses and of thus preventing the necessity for school closure. Mr. Adams reports that 18 cases of enteric fever were notified to him during 1895, and in one of the cases the evidence tends towards incriminating certain oysters eaten at Southend. The facts are these. Five persons went for the day to Southend, and the patient above referred to was the only one who ate oysters and the only one who was subsequently attacked with typhoid fever. Mr. Adams states that he has good reason for believing that this case is not the first instance of typhoid fever occurring at Maidstone which was to be traced to the consumption of infected oysters at Southend. We are glad to see that Mr. Adams has continued his very valuable records of the movements of subsoil water at Maidstone and that he has embodied the figures for 1895 in his report. A considerable portion of the interesting report before us is devoted to a consideration of the death-rate of Maidstone for the past twenty-six years, and a comparison of it with that of England and Wales for the same period. Mr. Adams shows that a large number of lives have been saved in Maidstone through the reduction of the death-rate during the period he deals with, and he demonstrates by an analysis of the figures the important fact that the chief reduction in the death-rate of Maidstone has taken place during the warmer months in each year—i.e., at a time when the effects of wise sanitary measures would be most likely to be apparent. This part of Mr. Adams's report will be read with much interest by those to whom the subject is important in Maidstone.

Southampton Port Sanitary District.—The port of Southampton is, Mr. Wellesley Harris states in his report, rapidly increasing in prosperity, and in a proportionate degree the risks of the importation of infectious disease are also multiplied. The sanitary authority is urged to draw up and adopt regulations under Section 125 of the Public Health Act similar to those in force at Liverpool and other large ports. During 1895 four cases of small-pox were imported by ships, but in each case the patient was removed from the vessel off Netley and conveyed to the Port Sanitary Hospital. Before the hospital was in use small-pox had to be isolated in the worst portion of Southampton, and the infection, Mr. Harris reports, rapidly spread from the hospital to the inhabitants living in the immediate vicinity. It is interesting to note that several cases of Beri-beri were brought by ships into Southampton Docks, and Mr. Harris was able to arrange for their admission into Netley Hospital. The small area of cubic space for seamen, as fixed by the Merchants Shipping Act, 1867, is made the subject of comment by Mr. Harris, who urges the desirability of increasing it. He points out that it is a difficult matter for the port sanitary officials to insist on improvement in structural details when they have already been passed by the Board of Trade. Doubtless the plan proposed by Dr. Collingridge in the report which we recently noticed in these columns would very materially assist in bringing about a better state of affairs. Arrangements are made at Southampton with the shipping companies frequenting the port for removal of small-pox cases prior to the arrival of the infected ship in port and for disinfecting infected articles and cabins. Mr. Harris refers to the prospect of the Quarantine Acts being repealed, and he not unnaturally suggests that part of the money saved by the disestablishment of the machinery of quarantine should be devoted to assisting port sanitary authorities in their work.

Bacup Urban Sanitary District.—Dr. John Brown reports that during September, October, and November, 1895, there were several cases of lead poisoning of a mild type in his district. Colic and anæmia, he states, were the chief symptoms. The cases were, it seems, associated with the public water-supply, and Dr. Brown suggests that the water committee should make experiments with lead piping lined with a non-metallic substance with a view to adopting it if it appears satisfactory. Most of these devices are somewhat costly and difficult to manage when bending is necessary.

Warrington Urban Sanitary District.—Mr. John Gornall, in referring to the necessity for providing a separate small-pox hospital as remote as practicable from the population, warns the Warrington sanitary authority in these words: "I would call to your remembrance the importance of the separation of a small-pox hospital from centres of population and remind you of the painful lesson that followed the contravention of this principle in our own case in 1892." Mr. Gornall quotes from the recent Memorandum on Isolation Hospitals issued by the Local Government Board, in which suggestions are made in reference to the conditions which should be observed in selecting a site for a small-pox hospital, with a view of diminishing as far as seems practicable at present the dangers which must necessarily attach to the establishment of such hospitals in the vicinity of towns. Mr. Gornall and the borough surveyor have, it appears, provisionally chosen a site which conforms to these conditions, and a map is supplied in the report showing the houses in the several zones around the site. It is surely unnecessary to insist that the Warrington sanitary authority should act without delay on the advice of their medical officer of health and not again expose their district to avoidable risks. Mr. Gornall reports that during last summer the river Mersey near Warrington gave off "most filthy emanations," which were a source of discomfort to the occupiers of the adjoining houses. The condition of the Manchester Ship Canal, owing to its proximity to Warrington, is a matter of much concern to the inhabitants of that borough, more especially as the

Digitized by Google

town is developing southward towards the canal. Up to the present there has been, Mr. Gornall states, but little to complain of in the condition of the Canal.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6261 births and 3598 deaths were registered during the week ending June 20th. The annual rate of mortality in these towns, which had been 17·8 and 16·7 per 1000 in the two preceding weeks, rose again last week to 17·3. In London the rate was 16·2 per 1000, while it averaged 18·1 in the thirty-two provincial towns. The lowest rates in these towns were 10·2 in Derby, 11·0 in Croydon, 13·2 in Swansea, and 13·7 in Bradford; the highest rates were 21·0 in Portsmouth, 21·6 in Birmingham, 21·9 in Sunderland, 22·4 in Manchester, and 23·0 in Salford. The 3598 deaths included 591 which were referred to the principal zymotic diseases, against 559 and 541 in the two preceding weeks; of these, 210 resulted from measles, 114 from diarrhœa, 111 from whooping-cough, 71 from diphtheria, 46 from scarlet fever, 39 from "fever" (principally enteric), and not one from small-pox. The lowest death-rates from these diseases were recorded in Blackburn, Swansea, Plymouth, and Brighton; and the highest rates in Leicester, Manchester, Salford, Oldham, and Hull. The greatest mortality from measles occurred in West Ham, Nottingham, Sheffield, Manchester, Oldham, Gateshead, and Hull; from scarlet fever in Salford; from whooping-cough in Sunderland, Cardiff, and Huddersfield; from "fever" in Birkenhead; and from diarrhœa in Salford and Leicester. The 71 deaths from diphtheria included 40 in London and 13 in Manchester. No fatal case of small-pox was registered during last week in any of the thirty-three large towns. There were 41 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 20th inst., against 19, 25, and 27 at the end of the three preceding weeks; 18 new cases were admitted during the week, against 3, 8, and 9 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2811, against 2679, 2717, and 2781 on the three preceding Saturdays; 309 new cases were admitted during the week, against 297, 318, and 352 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 230 to 183 in the three preceding weeks, further fell to 162 last week, and were 56 below the corrected average. The causes of 59, or 1·6 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Bradford, Newcastle-upon-Tyne, and in fourteen other smaller towns; the largest proportions of uncertified deaths were registered in Bristol, Swansea, Birmingham, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·2 and 18·5 per 1000 in the two preceding weeks, rose again to 18·9 during the week ending June 20th, and exceeded by 1·6 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·6 in Edinburgh and 15·7 in Paisley to 23·9 in Perth and 24·4 in Greenock. The 553 deaths in these towns included 33 which were referred to measles, 18 to diarrhœa, 16 to whooping-cough, 5 to scarlet fever, 5 to diphtheria, and 5 to "fever." In all, 80 deaths resulted from these principal zymotic diseases, against 81 and 69 in the two preceding weeks. These 80 deaths were equal to an annual rate of 2·7 per 1000, which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 25 and 21 in the two preceding weeks, rose again to 33 last week, of which 26 occurred in Glasgow and 5 in Dundee. The 18 deaths from diarrhœa showed a slight further increase upon recent weekly numbers, and included 5 in Glasgow and 4 in Edinburgh. The fatal cases of whooping-cough, which had declined in the five preceding weeks from 38 to 23, further fell to 16 last week, of which 13 occurred in Glasgow. The deaths referred to scarlet fever, which had been 8 and 4 in the two preceding weeks, were 5 last week, and included 2 in Leith. Of the 5 fatal cases of diphtheria, 2 were recorded in Glasgow and 2 in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 93 and 82 in the two preceding weeks, rose again to 87 last week, and were within 10 of the number in the corresponding period of last year. The causes of 34, or 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·8 and 23·7 per 1000 in the two preceding weeks, declined again to 22·5 during the week ending June 20th. During the past twelve weeks of the current quarter the death-rate in the city has averaged 23·1 per 1000, the rate during the same period being 3·2 in London and 1·9 in Edinburgh. The 151 deaths registered in Dublin during the week under notice showed a decline of 8 from the number in the preceding week, and included 18 which were referred to the principal zymotic diseases, against 8 and 10 in the two preceding weeks; of these, 6 resulted from diarrhœa, 5 from whooping-cough, 4 from scarlet fever, and 3 from "fever." These 18 deaths were equal to an annual rate of 3·7 per 1000, the zymotic death-rate during the same period being 3·2 in London and 1·9 in Edinburgh. The 6 fatal cases of diarrhœa exceeded the number recorded in any recent week. The deaths from whooping-cough, which had been 1 and 4 in the two preceding weeks, further rose to 5 last week. The 4 fatal cases of scarlet fever also showed a further increase upon recent weekly numbers. The deaths referred to different forms of "fever," which had declined from 5 to 2 in the three preceding weeks, were 3 last week. The 151 deaths in Dublin last week included 25 of infants under one year of age, and 38 of persons aged upwards of sixty years; the deaths of infants showed a decline, while those of elderly persons slightly exceeded the number in the preceding week. Three inquest cases and 5 deaths from violence were registered; and 49, or nearly a third, of the deaths occurred in public institutions. The causes of 8, or more than 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE ARMY MEDICAL STAFF.

BRIGADE-SURGEON-LIEUTENANT-COLONEL BARRY, M.D., Senior Medical Officer at Curragh, will retire from the service next month on his reaching the age of fifty-five.

ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel Henry Stannard retires on retired pay.

INDIA AND THE INDIAN MEDICAL SERVICES.

The following appointments have been made:—Surgeon-Major Addison, A.M.S., to Medical Charge of the Station Hospital at Kirkee. Surgeon-Captain C. E. Sunder, Resident Surgeon, Eden Hospital, Calcutta, to act as Civil Surgeon of Rangpur, during the absence on deputation of Surgeon-Major J. H. T. Walsh. Surgeon-Lieutenant C. R. Stevens, on supernumerary duty in connexion with anti-choleraic inoculation, to be Resident Medical Officer of the Medical College Hospital, Calcutta, vice Surgeon-Captain C. E. Sunder, transferred. Surgeon-Lieutenant Kukdy is transferred from the Poona to the Deesa District.

MILITIA MEDICAL STAFF.

Surgeon-Lieutenant-Colonel J. H. Wright, 3rd Battalion the Duke of Wellington's (West Riding Regiment): resigns his commission, also is permitted to retain his rank and to wear the prescribed uniform on his retirement.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Walter A. Atkinson, M.B., to be Surgeon-Captain. Surgeon-Lieutenant Henry George Outram Collett, 1st North Riding of Yorkshire Volunteer Artillery, to be Surgeon-Lieutenant. Surgeon-Lieutenant Samuel John James Kirby, 2nd Volunteer Battalion the Suffolk Regiment, to be Surgeon-Lieutenant.

Digitized by Google

VOLUNTEER CORPS.

Artillery: 7th Lancashire (the Manchester Artillery): Surgeon-Captain R. A. S. Daly to be Surgeon-Major. 8th Lancashire: Joseph David Wright, M.B., to be Surgeon-Lieutenant. *Rifle:* 13th Middlesex (Queen's Westminster): Bertram H. Lyne Stivens, M.D., to be Surgeon-Lieutenant. 1st Volunteer Battalion the Manchester Regiment: Surgeon-Lieutenant W. F. O'Grady to be Surgeon-Captain. 5th (Deeside Highland) Volunteer Battalion the Gordon Highlanders: Surgeon-Major G. Cran, M.D., to be Surgeon-Lieutenant-Colonel.

VOLUNTEER MEDICAL STAFF CORPS.

The Maidstone Company: Surgeon-Captain H. F. H. Barham resigns his commission.

THE RISING IN MASHONALAND.

There has been a good deal of hard fighting in Mashonaland, and the news generally is far from satisfactory, for it shows that the native rising has greatly extended. From the present aspect of affairs it looks very much as if reinforcements from this country for South Africa would be required. It is curious how little we know of the hospital arrangements and of the condition of the wounded in connexion with what is taking place. It seems that the experience obtained in Matabele in regard to the Lee-Metford bullet is very similar to that which was found to have been the case in Chitral—viz., that the bullet is defective in "stopping" power. The natives assert that unless the bullet struck a vital part it did not prevent the Matabeles from continuing the fight, although numbers of them died subsequently from the effects of the wounds inflicted by the Lee-Metford rifles. Experiments conducted in India and this country have led to some alterations by which this defect has been satisfactorily overcome. The alteration proposed in India will not, it is alleged, interfere with the present sighting of the rifle.

THE SOUDAN CAMPAIGN.

Since our capture and occupation of Firket and Suarda there has been little or no fighting in the Soudan. All who have had an opportunity of seeing the country around these places seem to be agreed as to the correctness of the information obtained by the Intelligence Department of the Egyptian Army. The rule of the Dervishes has been one of terrible cruelty; the country, once so fertile and cultivated, has been quite laid waste; all trade has been destroyed, and the native population generally are only too glad to welcome an expedition which will rid them of the oppressive rule under which they have been living. The government of the Egyptians when they held the country was no doubt also very bad, but we may confidently believe that under English guidance it will soon be very different and that the unfortunate people will be allowed to follow their agricultural pursuits in peace. The Anglo-Egyptian expedition is healthy, and the hospital and sick transport services are working satisfactorily.

RETIREMENT OF SURGEON-LIEUTENANT-COLONEL CARLESS OF DEVIZES.

Surgeon-Lieutenant-Colonel E. N. Carless, M.B., C.M. Aberd., the medical officer of health for Devizes, who has been associated with the 2nd V.B. Wilts Regiment as medical officer for nearly a quarter of a century, has just resigned his commission, and has been granted permission to retain his rank and continue to wear the uniform of the regiment on retirement. He has the volunteer officer's decoration, and has rendered much useful service at regimental and brigade camps and he inaugurated the ambulance movement in the battalion, which has since led to the establishment of a properly equipped bearer company for the brigade. His retirement is much regretted.

FEMALE DEVOTION REWARDED.

The French War Minister has awarded medals of honour to two ladies in connexion with the Madagascar Expedition. The recipients are Madame Jay (in religion Sister Zénaïde), Superior of the Saint Joseph de Cluny Mission, who throughout the operations exhibited the utmost devotion in the hospital at Majunga, and who, moreover, reckons upwards of fifteen years' service in the island; and Miss Christina Byam, for thirteen years the directress of the English hospital at Soavinandriana. The latter establishment served as an annex to the military hospital at Antananarivo, being utilised chiefly for sick officers and wounded soldiers.

SURGEON-MAJOR-GENERAL TAYLOR.

We are glad to learn that Surgeon-Major-General W. Taylor, M.D., is to remain supernumerary pending his absorption in due course when the officer who stands next senior to him as Surgeon-General is promoted. It is only a fair and just arrangement to the medical service generally that the State should not reward an officer at the expense of other officers by retarding their promotion. It is quite right that an officer should be rewarded for services rendered, and Surgeon-Major-General Taylor's work in the late campaign in Ashanti was fully entitled to recognition. We have only to add our congratulations on his promotion.

Correspondence.

"Audi alteram partem."

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—In formulating any scheme for the improvement of the constitution of the Council it is clearly evident that one must have regard, in the very first instance, to the *raison d'être* of the College itself. This has been set forth, first in the Charter of 1800, and repeated in many subsequent Charters, as being for "the promotion and encouragement of the study and practice of the art and science of surgery." This duty was entrusted to a body which has had various names and is now known as the Council of the College. It was given the privilege of admitting men under certain conditions to the Membership of the College, and thereby of licensing them to earn a living by becoming practitioners of surgery. Until the year 1844 the members of the Council (twenty-one in number) were self-elective—i.e., when a vacancy occurred it was filled up by the votes of the remaining members from the general body of Members. A council so constituted could, of course, have no claim to the confidence of the general body of Members, and, as might have been expected, abuses of many kinds were rampant in the management of the College. By the Charter 7th Victoria, 1843, however, a master hand in diplomacy altered this state of affairs. By this charter a new class of Members was created, who were to be known as "Fellows."

The Council was given power to elect before the expiry of one year from the date of the charter such Members of the College as seemed to them fit and proper persons to be created "Fellows"; and after this period no person was to obtain the Fellowship unless he had attained the age of twenty-five and complied with the regulations of the Council, nor unless he had passed such special examination as the Council might from time to time think fit. Among these regulations one of the most important was that of the extension of the usual period of study. It was further declared by this Charter that, while the already existing twenty-one members of Council were to hold office, as heretofore, for life, in July of the following year three new members were to be added to the Council, and that as vacancies occurred by the death of original or life members these were to be filled up in the same manner as the additional three of 1844. Now herein comes the master stroke of far-sighted diplomacy. These new members of Council were to be elected by the general body of Fellows, and, further, from their number only. In this way perhaps the greatest impetus to the "promotion and encouragement of the study and practice of the science and art of surgery" was given which the annals of the College can boast of. Men of good parts were directly encouraged to spend a longer time at their studies and to aim at a higher diploma. As inducements to this they were made eligible for membership of the Council, and they alone were empowered to vote for members of this body. While this encouragement to the pursuit of higher surgery was given, the old-time, close, and utterly objectionable constitution of the council was abrogated, and not only so, but security was given that future members of it should be chosen only (as far as could be done) from those who, broadly speaking, were the best educated Members of the College, who had shown themselves to be the most enterprising and energetic, and who perhaps took the greatest interest in the affairs of the College. I need hardly pause here to say that most undoubtedly there are many men among the ranks of "Members" simply who are in every respect as worthy of the rank of Fellow as if they possessed it, but who through

Digitized by Google

force of circumstances have chosen to remain Members only. I speak in a broad sense.

It is proposed now that "Members" of the College, as such, should also elect representatives on the Council. For what object? And what will be the result if the proposal be carried out? The use of the word "representative" in connexion with Members of the Council is very singular. An examination of the Charters gives no warrant for it whatever. The Council is a body created or chosen to carry on the work of the College. No Member of it has any warrant for saying that he is such as representing the interests of any portion of the body corporate. He represents the entire body—the College itself. There are no interests of the Fellows apart from those of the Members, nor have the latter any apart from those of the former. The Council is an academic body with objects and functions apart from those of the profession generally. They have to admit candidates into the ranks of the profession, to maintain the library, museum, &c., and to uphold the interests of those who hold their diploma. Can it be truly said that they fail to fulfil those duties? As has been said by Sir Wm. Erichsen, "The only way to establish the claims of the Members would be to rest their case on the only ground that would be unassailable—namely, that the Council has been negligent of, or indifferent to, the conduct of its affairs, and that its interests, material, educational, and scientific, have consequently suffered in its hands."[1] Can this be truly said of the Council at the present day? I confess that when I first took my seat as a Member, I was somewhat prejudiced against it as a body, partly by reading *ex-parte* articles in the medical journals, but above all by the gratuitous difficulty which was thrown in one's way in voting for members of the Council. For eleven months in the year one was left in peaceful happiness. Then came the time of an election, with a most roundabout, troublesome system of voting, which was agonising and blood-boiling, and led one to think that the articles one had read must be true, and that the Council was a conservative, out-of-date body of men. Happily, this is now all changed, and the manner of voting is simplicity itself. Having uttered this growl I am happy in making the *amende honorable*, and declaring that I have found the Council most anxiously solicitous to carry out its duties in a business-like manner. Indeed, the very opposite of my previous ideas now possesses me, inasmuch as it appears sometimes over anxious to appease its critics, and to "wear its heart upon its sleeve for daws to peck at." I hold that a member of Council should be free to act as his best judgment advises him, and not to feel hampered as the nominee or representative of some party which has "carried him in" to support some line of policy. But if in the future "representatives" of the Members be sent to the Council, what then? After a little while some of those gentlemen would begin to ask themselves, Why are we here? The result would be the introduction of topics for discussion wholly apart from those pertaining to an academic body, but which rightly belong to the whole republic of the medical profession, wheresoever its Members may have gained admittance to it. These are subjects for the consideration of voluntary societies, such as the British Medical Association, the Medical Defence Union, and so on, and are concerned with the furtherance and protection of the interests of their members, individually or as a whole. To introduce such subjects—most legitimate in their proper place—would inevitably tend to lower the position of the Council.

An argument for the representation of Members has been used which appears to me to be the veriest clap-trap. It is said that taxation means representation. But when a man prepares to enter the medical profession and makes up his mind as to which portal he will pass through he knows what the costs are. He pays his fees and he receives his *quid pro quo:* he receives a Licence to practise and to earn his livelihood by the practice of surgery. The expenses of the institution which gives him his Licence must be provided for, and if not by these Licentiates, then by whom? Notwithstanding all the able articles which have appeared in the columns of THE LANCET to the contrary, I cannot believe that there is any widespread desire on the part of Members of the College to be represented on its Council. It appears to me that the agitation is kept up by a mere handful of men in and around London, who meet over and over again. Nor is there any extensive knowledge of "College politics" either among the Members or Fellows. Most of them to whom one speaks on the subject say, "What is all the row about?" or something equivalent.

Finally, I feel very strongly that if this movement be successful it will be a distinctly retrograde step. Men will think twice before undergoing the severe ordeal for the Fellowship, with its barren honours. They will think, Why all this when I can get as much by being a Member? And hence the promotion of the science and art of surgery will suffer. I appeal strongly to my colleagues in the Fellowship to do all they can to resist this movement.

I am, Sirs, yours faithfully,

Manchester, June 20th, 1896. JAMES HARDIE.

*** Our own views are, as is well known, diametrically opposed to those set forth above by our correspondent. But we are always desirous to give fair hearing to both sides, and willingly publish the letter of a distinguished provincial surgeon, who is himself a member of the Council of the College.—ED. L.

[1] Rivington: The Medical Profession. 1887.

DIRECT REPRESENTATION ON THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—As my esteemed colleagues in the representation of England and Wales have thought that the time has come for announcing their resignation, it is but respectful to my fellow practitioners that I should take this early opportunity—by your favour—of saying that it is my intention to solicit again the honour of re-election at their hands. Though a bad judge, I am not conscious of having done anything in the Council to discredit the principle of direct representation, or to forfeit the kindness and confidence of the profession which have twice placed me there as one of its elected representatives. Other opportunities will soon occur of stating my views to the registered practitioners of England and Wales; but I shall ask you meanwhile to kindly publish the following correspondence, which will explain my opinions on some questions of importance. I may be allowed in one sentence to say that, whatever the choice of the profession at the next election, I consider the loss of Mr. Wheelhouse and Sir Walter Foster a very real one to the Council and to the profession.

I am, Sirs, your obedient servant,

Highbury, N., June 23rd, 1896. JAMES GREY GLOVER.

Incorporated Medical Practitioners' Association,
Registered Office, 11, Adam-street, Strand, June 15th, 1896.

DEAR SIR,—I am directed by the Central Council of this association to say that as it is reported that you may probably present yourself as a candidate for election as a direct representative on the General Medical Council at the forthcoming election, my council would be glad to know your views on questions of importance to the medical profession. The council would therefore feel obliged if you would favour me with an answer to the following questions at your earliest convenience. Thanking you in advance.

I am, dear Sir, yours faithfully,

Dr. J. G. Glover. FRANK GREAVES, Hon. Sec.

1. Would you, if elected, support a motion in the General Medical Council advocating a complete reform of the Medical Acts?
2. What action would you take in the Council concerning a proposal to register midwives as independent practitioners?
3. Would you support any motion in the Council condemning the holding of appointments under medical aid associations which make a profit out of their medical officers, and which canvass from door to door for patients?
4. Would you support a motion in the Council asking for the appointment of further direct representatives upon the Council, as provided for in the Medical Act of 1886?

25, Highbury-place, June 19th, 1896.

DEAR MR. GREAVES,—As it is my intention to offer myself again as a candidate for the office of direct representative of the profession—to which the profession has twice done me the great honour to elect me—I gladly respond to your letter as the Hon. Sec. of the Incorporated Medical Practitioners' Association inquiring my views on four specific questions. Yours very truly, J. G. GLOVER.

1. Would you, if elected, support a motion in the General Medical Council advocating a complete reform of the Medical Acts?

I should support an amendment of the Acts in the way of strengthening and making more clear and effective the clauses against all false, fraudulent, and unqualified forms of practice as well as against the misleading use of titles, and of increasing the proportion of direct representatives of the profession.

2. What action would you take in the Council concerning a proposal to register midwives as independent practitioners?

While impressed with the necessity of saving poor lying-in women from death and disease at the hands of midwives ignorant of the first principles of puerperal hygiene, I should be strongly opposed to any Bill which did not make clear the non-medical function of the midwife and the need for her being supervised by a medical practitioner in all unusual cases.

3. Would you support any motion in the Council condemning the holding of appointments under medical aid associations which make a profit out of their medical officers and which canvass from door to door for patients?

Such methods of practice are inconsistent with justice to private practitioners, with the best traditions of the profession, and with the

Digitized by Google

real interests of the public. Primarily the condemnation of them is the duty of the qualifying bodies of the profession. (I have taken some pains in the Council—not without some success—to quicken in all the qualifying bodies the sense of responsibility for the use of their disciplinary powers.) But I have already proposed or supported their condemnation in the Council, and should do so again if necessary.

4. Would you support a motion on the Council asking for the appointment of further Direct Representatives upon the Council as provided for in the Medical Act of 1886?

I should support such a motion with pleasure.

To the Editors of THE LANCET.

SIRS,—At the annual meeting of the Lancashire and Cheshire Branch of the British Medical Association held to-day it was resolved to recommend and support the candidature of Dr. Samuel Woodcock, Dr. Glover, and Dr. Lovell Drage as Direct Representatives of the medical profession in the General Medical Council.

I am, Sirs, yours faithfully,

Southport, June 24th, 1896. JAMES BARR, Hon. Sec.

To the Editors of THE LANCET.

SIRS,—I read in THE LANCET of to-day that Sir Walter Foster and Mr. Wheelhouse will not seek re-election on the General Medical Council. I regret this step on the part of Sir Walter, as I have thought it useful to have a member in Parliament on the Council. Sir Walter, in conjunction with his colleagues, Mr. Wheelhouse and Dr. Glover, have done much useful work in the interest of the profession and in the cause of the general practitioner, but I think with the voice of the great majority of the profession, as they evidently do think, that the three direct members of the General Medical Council should all be general practitioners. As a probable candidate I have enclosed you my answers to the questions submitted to me by the honorary secretary of the Incorporated Medical Practitioners' Association. At the last election I obtained 4818 votes; should I again seek the honour this encouragement with many promises of support that I have received from my friends must be my apology.

I am, Sirs, yours very truly,

FREDERICK H. ALDERSON, M.D.,

Vice-President of the Incorporated Medical Practitioners' Association, Hon. Vice-President of the West London Medico-Chirurgical Society.

June 20th, 1896.

Dr. Alderson's Reply to Questions submitted by the Hon. Sec. of the Incorporated Medical Practitioners' Association.

[COPY]

1. Yes, the amendments proposed by the British Medical Association meet with my approval and with a few additions might be desirable to accept and all perhaps that would be attainable.

2. I should oppose any Bill that would create a new order of partly qualified practitioners, and thus violate the principle of the Bill of 1886. At the same time I am not opposed, and believe some legislation is necessary to control and prevent the present unlicensed (and in many cases lamentably ignorant) practice of midwives in poor neighbourhoods. The midwife should be known and legally described as an obstetric nurse and the term midwife should never be used officially; and in my opinion it is desirable that the practice of the obstetric nurse should be under the supervision of the general practitioner, and in the present crowded state of the profession is quite feasible. I am in favour of the suggestion of Dr. Fraser as mentioned in THE LANCET of Feb. 29th, and especially as to the need for the registration of still births.

3. Yes, I am strongly opposed to medical aid associations that make a profit of the skill and labour of their medical officers and which canvass from door to door. It is this practice that has proved so inimical to the interests of the general practitioner, but in my opinion the only effectual remedy is to render the practice illegal by the General Medical Council.

4. Yes, I have advocated in my speeches and by writing for many years for an increase to the number of the direct Members to the General Medical Council, and this effort shall have my strong support.

June 16th, 1896. FREDERICK H. ALDERSON, M.D.

To the Editors of THE LANCET.

SIRS,—Since the announcement in your issue of Saturday last that Sir Walter Foster and Mr. Wheelhouse do not propose to offer themselves for re-election as direct representatives on the General Medical Council I have received numerous inquiries as to whether I purpose to again come forward as a candidate. I shall feel obliged if you will allow me to state through your columns that when the proper time arrives I intend to issue an address to my brother practitioners soliciting their support at the forthcoming election.—I remain, Sirs, yours faithfully,

GEORGE BROWN,

Ex-President of the Incorporated Medical Practitioners' Association.

Charing-cross-road, W.C., June 24th, 1896.

To the Editors of THE LANCET.

SIRS,—The announcement in THE LANCET of June 20th that Mr. Wheelhouse and Sir Walter Foster will not seek re election on the General Medical Council is hardly a surprise. That they should have been willing to fight for ten years the battle of the profession on a Council in which the direct representatives are outnumbered as five to one proves two things: (1) their *patience*, and (2) their *fighting capacity*. But it must have been a weary warfare in a hopeless minority, "supported" by that disorganised rabble called "the profession." And I wonder how much encouragement, how many "votes of thanks" they have received? ("Thanks" cost little and should be plentiful.) I noticed lately in the pages of the *British Medical Journal* that Dr. Lovell Drage had been invited to become a candidate in opposition either to Mr. Wheelhouse or Sir Walter Foster, on the ground that a "general practitioner" was required. Now, I have the highest regard for Dr. Drage, but to those who invited him to oppose—if they be general practitioners—I would say they are guilty of base ingratitude. No two men could have more honourably and faithfully carried out the duties entrusted to them by the vote of general practitioners than Mr. Wheelhouse and Sir Walter Foster. But, Sirs, the purpose of this letter is not to praise those who are beyond praise, but to ask, Is it really worth while filling up the vacancies on the General Medical Council which will occur next November?

I suggest the negative for the following general reasons: (1) That the Government of the profession by the General Medical Council is virtually "government by schoolmasters"; (2) that the work done by it fails to justify its existence; (3) that if the profession at large elect members (direct representatives) they by so doing recognise an effete body.

Better let it severely alone—"let it stew in its own gravy"—and I only hope that Dr. Glover and Dr. Bruce will follow the lead of Mr. Wheelhouse and Sir Walter Foster.

I am, Sirs, yours faithfully,

June 22nd, 1896. COLIN CAMPBELL.

THE ROYAL MEDICAL BENEVOLENT COLLEGE.

To the Editors of THE LANCET.

SIRS,—May I ask for space in your columns to acknowledge the receipt of 500 guineas collected from his patients by Mr. Hames in aid of the funds of the Royal Medical Benevolent College. I venture to hope that such success achieved by one medical practitioner may incite others to aid by enlisting the active practical sympathy of their patients in their several districts. I would take this opportunity of thanking the members of many of the branches of the British Medical Association for the grants voted in aid of the College. Last week the South-Eastern Branch, with which I have been associated all my professional life, voted £21 to the College and £21 to the British Medical Benevolent Fund. Such aid and such sympathy are simply invaluable to the governing bodies of both charities.

I am, Sirs, yours truly,

C. HOLMAN, M.D.,

Treasurer, Royal Medical Benevolent College.

Soho-square, W., June 23rd, 1896.

"THE CAUSE OF MALARIA."

To the Editors of THE LANCET.

SIRS,—The personal equation has to be discounted in assessing the value of all observations, particularly all microscopical observations. When a statement is made which is in complete opposition to general experience, cautious men, before accepting the statement, require to know something about the capacity and character of the person who makes it. In a matter so special and difficult as blood microscopy the observations of the amateur have a very different value from those of the practised and proved expert. The statements of the former, before they can be accepted, must be carefully substantiated by detailed evidence and, if possible, confirmed by men of recognised capacity, and this more especially if it be sought to overthrow on the strength of such statements so well established a theory and one so pregnant with vast practical consequences to mankind as that which recognises the causal relationship of the phenomena of malaria to Laveran's bodies. The responsibility of leading or misleading

Digitized by Google

opinion on so momentous a subject is very grave indeed, and it is the duty of any one who assumes this *rôle* to exercise every precaution in guarding against error and to produce his vouchers when called on.

These remarks are intended to be *apropos* of some of the statements made by Surgeon-Lieutenant-Colonel Lawrie in his paper in THE LANCET of June 20th. Therein he says of a certain patient who had fever for the first time last September that "crescents were discovered in his blood the day after the first attack commenced." He does not mention the name of the observer, and he gives no particulars which would enable a reader to form an opinion on the value of the observation. In common with many others I have always believed that the crescent form of the malaria parasite does not appear in the blood until the end of the first week or during the second or third weeks from the commencement of certain types of malarial fever. This has hitherto been the experience of all careful and practised observers who have given special attention to the point. Not to mention continental names, Thayer and Hewetson remark: "These forms are not seen during the first days, but appear generally during the second or third week." Until we have further details, therefore, Surgeon-Lieutenant-Colonel Lawrie must not expect pathologists to accept this statement so contrary to general experience. Further, if this observation was made by any or all of the "three competent observers" who afterwards failed to find the malarial parasite in the same patient on the first day of a subsequent attack of ague pathologists will be inclined to doubt the capacity of these observers, and therefore the value of the later observation and, of course, the validity of the conclusions Surgeon-Lieutenant-Colonel Lawrie draws from it. Assuming, however, that this last observation was correct (as it very well may be), it by no means follows that the organism which was subsequently found in the blood was the consequence and not the cause of the fever, as Surgeon-Lieutenant Colonel Lawrie has argued on *post hoc* principles. Spleen and liver and other organs, and not the peripheral blood, are well known to be the principal habitats of most varieties of the malarial parasite. If this be the case, for all Surgeon-Lieutenant-Colonel Lawrie knew and for all he has advanced, or, rather, not advanced, Laveran's bodies may have existed in the spleen or liver at the very time when his "three competent observers" searched in vain for them in finger blood. Why should an organism confined to the spleen not cause fever? A streptococcus in the skin gives rise to the fever of erysipelas. Local infections are constantly associated with fever. Why not plasmoidal infection of the spleen?

I would ask Surgeon-Lieutenant-Colonel Lawrie to explain what he means by "swarming movements" The malarial parasite exhibits three or four forms of movement which Surgeon-Lieutenant-Colonel Lawrie seems to have confounded together: (*a*) amœboid movement; (*b*) slow translation of pigment particles while the parasite is alive and within the red blood corpuscle; (*c*) more violent translation of pigment in the crescent-derived sphere and flagellated organism; and (*d*) Brownian movement of fragmented pigment in those intra-corpuscular bodies which from compression by the cover-glass have been forced from the corpuscles and are lying free and probably crushed and dead in the liquor sanguinis. Intra- and extra-corpuscular "swarming" are, therefore, not always the same thing. One is a vital movement, the other—unless in the case of the crescent-derived spheres and flagellated bodies—is simply a Brownian movement of dead, disorganised matter. The "swarming" of leucocytes is, I presume, merely the ordinary vital amœboid movement of these bodies—a movement in no way analogous to the different kinds of movement of pigment in the malarial parasite. What Surgeon-Lieutenant-Colonel Lawrie describes as the evolution of a rosette body is easily explained. When the preparation in question was first put up, doubtless the film of blood was still rather thick, and, in consequence, the only part of the rosette readily seen was the more conspicuous central block of black pigment. After a time the attraction of cohesion between the slip and the cover-glass gradually compressed the corpuscle, spreading it out and rendering its contents more visible, so that the spores of the rosette came gradually and distinctly into view. This is a common occurrence and familiar to all who work with malarial blood. But even assuming, with Surgeon-Lieutenant-Colonel Lawrie, that Laveran's bodies are merely leucocytes inside or outside red blood corpusles, how explain, unless on the ground of imperfect visibility or observation, the fact that this particular leucocyte was not seen from the first? Does Surgeon-Lieutenant-Colonel Lawrie wish his readers to infer that a white blood corpuscle was created under his eyes? The reappearance of what Surgeon-Lieutenant-Colonel Lawrie calls "the original cell wall" I cannot pretend to explain, unless on the supposition that it had never disappeared, only, in consequence of imperfect focussing, seeming to do so. I cannot understand what Surgeon-Lieutenant-Colonel Lawrie means by the disappearance and reappearance of the cell wall of the leucocyte. Has the leucocyte a cell wall?

Those interested in this subject would, I feel sure, be glad if Surgeon-Lieutenant-Colonel Lawrie would re-state more explicitly and in greater detail the facts he argues from, and, above all, if he would give his authorities as well as careful drawings bearing on what he calls "signs of the well-marked relation of Laveran's bodies to the white blood cells." I confess, although I read it very carefully, I was not convinced by his first paper that any such relationship existed.

I am, Sirs, yours truly,

June 22nd, 1896. PATRICK MANSON.

PREVENTION OF DISASTER AT SEA.

To the Editors of THE LANCET.

SIRS,—The time is opportune once again to attempt to open the eyes of the authorities at the Board of Trade to the necessity of securing prompt and effective legislation as regards the prevention of disaster at sea as far as it depends on "colour- and night-blindness in look-out men" on board steamers. This is a special factor in collisions. The recent awful calamity will no doubt stir up engineering art to devise some means of greater precision and security in bulk-head appliances, so that under no circumstances could such an immediate and wholesale disaster occur. Our art is also concerned with prevention. Should two steamers crossing the Atlantic meet in swift opposing contact—which may God avert—there would be such loss of life as to make the nation tremble, and it might be found after the disaster that due attention had not been paid to the "eyes of the ship." Where, then, would this responsibility rest? The chilly reception accorded to the notable deputation of experts by the late President of the Board of Trade no doubt many of your readers remember. *Cui bono?* Unless the present Government is benumbed by the exuberance of legislative work or overplus of majority, it is to be hoped that a beneficent measure aiming at the saving of life from preventable disaster at sea might receive attention if properly brought to Mr. Ritchie's notice. I need only say I turn to THE LANCET as the sentinel of the profession to urge that this most pressing and ever imminent danger be averted which, if pooh-poohed, will some day bring wide-spread destruction and grief. Twenty-five years ago this was foreseen by me, and I make no doubt that hundreds of unrecorded deaths have ensued through neglect of the measures of precaution and prevention then urged, and many unexplained collisions due to similar causes have never been satisfactorily accounted for.

I am, Sirs, yours obediently,

R. A. CALDWELL.

Henrietta-street, Cavendish-square, W., June 22nd, 1896.

"LITHOTRITY: COMPLICATED AND SIMPLE."

To the Editors of THE LANCET.

SIRS,—I have read with much interest the lengthy paper on the above subject recently published in THE LANCET by Mr. Milton of Cairo, and as litholapaxy is an operation I am called upon to perform about forty times every month I should like to offer some remarks thereon. First, Mr. Milton is to be congratulated upon having successfully crushed what is almost certainly the heaviest stone ever thus treated—one of twelve ounces—the largest ever removed in this manner at the Civil Hospital here having been eight ounces, crushed by my predecessor, Surgeon-Lieutenant-Colonel Henderson, I.M.S., and I do not know of any other heavier calculus having been crushed in India. Mr. Milton gives rather faint praise to his own modification of the lithotrite and evacuator combined, and I would add to the objections he already sees to the use of the instrument

Digitized by Google

the great danger of presenting the unprotected serrated surface of the projected male blade to the bladder-wall during evacuation; thus the instrument is not only comparatively inefficient, but, what is worse, positively dangerous. The definition given of perineal lithotrity is generous, and the form of the operation effected by Mr. Milton is very slightly removed from that by the old stone crusher, as it is done through what is practically a lithotomy wound and entails as long a stay in hospital as the old lithotomy.

Mr. Milton fails to see what is gained by Keith's primal litholapaxy (the only operation, in my opinion, properly so-called), and then adds that he would "limit its application to cases in which it is impossible to pass the lithotrite down the penile portion of the urethra." If we interpolate the words "of sufficient power" after the word "lithotrite" in the above sentence we indicate precisely the cases for which Keith devised, performed, and recommended the operation, and the experience at Cairo, though small as compared with that at some Indian stations, must supply many such instances both among children and adults. I append the last five years' results of (1) urethral litholapaxy and (2) Keith's operation at the Civil Hospital, Hyderabad, Sind.

Urethral litholapaxy.		Cases.	Deaths.	Perineal litholapaxy.		Cases.	Deaths.
Mortality per cent., 1·31.	1891 ...	221	8	Mortality per cent., 1·97.	1891 ...	79	2
	1892 ...	328	5		1892 ...	45	1
	1893 ...	556	4		1893 ...	46	0
	1894 ...	313	3		1894 ...	56	2
	1895 ...	337	3		1895 ...	26	0
		1754	23			253	5

This represents the work of Keith up to May, 1894, and of Henderson for the rest of the period, and gives results which have probably never been surpassed, and which almost disarm criticism as to the methods pursued, while the figures for single years—e.g., 1893, the last year of Keith's service—are almost phenomenal. My own results since I took charge here on Feb. 1st last are—urethral litholapaxy, 151 cases and 1 death; perineal litholapaxy, 10 cases and 1 death; in all, 161 cases and 2 deaths; but the figures are too small to draw conclusions from.

I am, Sirs, yours faithfully,

RICHARD BAKER, M.A., M.D. DUB.,
Surgeon-Major, I.M.S.; Acting Civil Surgeon,
Hyderabad, Sind.

June 2nd, 1896.

"TOXICOLOGICAL EFFECTS OF CREOLIN."

To the Editors of THE LANCET.

SIRS,—We note in your current issue that you have commented on an article of Professor Hobday's on "Toxicological Effects of Creolin." We need not point out to you the advantages contained in our preparations, as they are too well known to you, and we feel sure also that you are convinced that if our preparations and "creolin" are used in a properly diluted form, as indicated by us in medical literature—viz., in 1 per cent. to 3 per cent. solutions as directed—absolutely no harm can be done. The experiments by Professor Hobday are carried on with "creolin" in practically undiluted form, and of course no one can expect good results; just as much nobody would expect a tenfold dose of any potent drug if taken would pass off harmless; but what we say, plainly, and which we feel sure is correct, is that if our preparations and "creolin" are used in a properly diluted form no harm whatever can arise, and therefore we believe that we are perfectly entitled to quote our preparations "innocuous."—We are, Sirs, yours faithfully,

For Jeyes' Sanitary Compounds Co., Limited,
WM. PLANNER, Secretary.

June 24th, 1896.

MEDICAL CERTIFICATES AND BOARD SCHOOLS.

To the Editors of THE LANCET.

SIRS,—At a meeting of the Council of the London and Counties Medical Protection Society, Limited, held on the 2nd inst. they had before them a complaint of Mr. R. B. Hunt to the effect that the parents of a child attended by him had been prosecuted for the non-attendance of their child at school, notwithstanding that Mr. Hunt had given a certificate of the child's unfitness to attend which the school attendance officer declined to accept as it did not state the exact nature of the child's disease. After discussion the following resolutions were unanimously passed:—

"The Council is strongly of opinion that a medical certificate concerning absence from school without stating the condition of the absentee's disease should be considered satisfactory by the School Board. The Council is also strongly of opinion that in no circumstances should a medical man in his certificate name the disease from which the absentee is suffering unless he *shall* have been requested to do so by the parents or responsible guardian of the scholar."

At a meeting of the West Ham School Board on June 9th the chairman called attention to the above prosecution, and said the school attendance officer exceeded his duty in taking proceedings without consulting the school attendance committee. The chairman also said he would be quite satisfied with a medical man's certificate that a child was unfit to attend school, even though the nature of the illness was not stated—in fact, he did not believe the board had any legal right to demand a certificate as to the nature of the illness and that it might be a breach of medical etiquette to state what the illness was.—I am, Sirs, your obedient servant,

HUGH WOODS,
Hon. Secretary London and Counties Medical Protection Society, Limited.

New-court, Lincoln's-inn, W.C., June 22nd, 1896.

"THE REMUNERATION OF MEDICAL MEN."

To the Editors of THE LANCET.

SIRS,—I read with great interest "M.D.'s" letter on the above subject in THE LANCET of June 20th. There is undoubtedly much discontent and dissatisfaction amongst medical men, and I have heard many medical men say that they were extremely sorry they had ever qualified, not because they were not fond of their work or profession, but because they found themselves after years of hard work unable to pay expenses. It is all very well for hospital lecturers and consultants to din into the student's ears what a noble and glorious profession he has adopted, &c., but they do not consider what those students are to do when they are fully fledged medical men. The consultant, as a rule, has very little notion of what general practice is. I remember some years ago listening to an opening address delivered by a physician to one of our London hospitals in which he made the following statement: "If the practitioner is in any doubt about the diagnosis or is unable to diagnose a case he should never prescribe." This was told to an assembly of students, of whom some 95 per cent. or more would become general practitioners. I fear the gentlemen who acted on this advice would not have many patients to look after at the end of a few months. I think parents and their sons who wish to enter our medical schools should be told before joining of the struggle for existence and the overcrowded condition of the profession which now exists. The leading members of our profession should consider that we are not all in their position, and, to put it plainly, the general practitioner has his living to make. This, I fear, the hospital surgeon or physician ignores, and the great aim and object of our medical schools is to get as many students as they can and not to bother themselves in the least what is to become of them afterwards. The General Medical Council should be increased considerably by members of the profession in general practice; they are far better able to judge of the wants of the general practitioner and also know more about the competition, poor remuneration, and struggle for existence than the medical man in a large consulting practice. I feel certain that many reforms must take place before many years. What is the outlook for the general practitioner at present? The profession already much overcrowded, fees small, the number of men qualifying increasing every year, the club or provident dispensary system, members paying 2*s.* 6*d.* per annum for medicine and advice, &c. The numbers can, and I think will, be reduced, and this can be done by raising the standard of the entrance examination and making it competitive, so that only a fixed number of new men are admitted. I am extremely pleased, Sirs, to see you taking this matter up, and I am sure you will by so doing receive the support and thanks of the whole profession.

I am, Sirs, yours faithfully,

M.R.C.S., L.R.C.P.

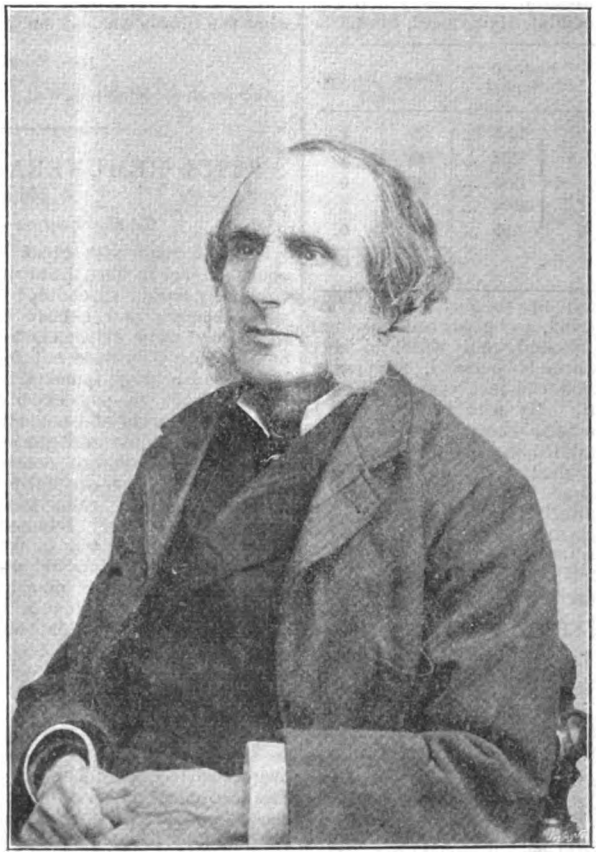
Obituary.

WILLIAM CHOLMELEY, M.D. ST. AND., F.R.C.P. LOND.

ON June 18th the consulting physician of the Great Northern Central Hospital entered into well-earned rest. Dr. Cholmeley was so intimately connected with the Great Northern Hospital from practically its foundation that it seems only right in this notice of his career to make this the most prominent feature.

Dr. Cholmeley was born in 1823 at Waynfleet, Lincolnshire, of which place his father was rector. He received his medical education first of all from a local practitioner, to whom he was apprenticed, and afterwards at St. Bartholomew's Hospital. In 1844 he went to Paris, and after studying there for about a year returned to London and set up as a consulting physician in Russell-square, whence in 1871 he removed to 63, Grosvenor-street. In this year too he married Louisa, the eldest daughter of the late Lieutenant-Colonel H. Ross Gore, C.B., who survives him. From 1873 to 1883 he was editor of the now extinct *Medical Times and Gazette* and was also medical officer of the Eagle Insurance Office from 1871 to 1894. About this latter date his memory began to fail and he had to give up all active work. In this state he remained, with occasional fluctuations for better or worse, until the beginning of 1896, when he began to show signs of a restlessness quite foreign to his nature; and so gradually his strength wore out and he passed quietly away after three days' unconsciousness on June 18th. Of his work at the Great Northern Central Hospital, an institution which for nearly forty years he helped to grow from very humble beginnings to the present magnificently appointed block of buildings, the following extract from an appeal published by the hospital will speak better than any words of ours can do:—



WILLIAM CHOLMELEY, M.D. ST. AND., F.R.C.P. LOND.

(From a photograph by Fradelle and Young.)

"On June 28th, 1856—the eighteenth anniversary of the Queen's Coronation—Dr. Croft and two surgeons (Mr. Statham and Mr. J. L. Statham) held a preliminary meeting, at which it was resolved to establish an institution to be called 'The Great Northern Hospital.' Four weeks later premises were secured at King's Cross and an honorary secretary was appointed. In September it was decided that a Council should be formed, consisting of medical and lay members, and its first meeting for business was held on Dec. 18th, ten members being present. So widely appreciated were the services rendered, even at this early period, that it was found necessary, in February, 1857, to enlarge the building, and on May 18th following the first medical staff, consisting of two consulting physicians, two physicians, three surgeons, four junior surgeons, one obstetric physician, one ophthalmic and one aural surgeon, and two dentists, was appointed. Up to this time there were no in-patients, but on July 29th two wards were opened, containing ten beds for men and six for women. On June 25th, 1858, Dr. Cholmeley was appointed junior physician and Mr. W. Adams surgeon, and in the following year the former was unanimously elected a member of the Council, an event which had a most important influence in the subsequent history of the hospital. Towards the close of the year 1860 external disturbing influences began to manifest themselves. A notification was received from the Metropolitan Railway Company that it was their intention to apply for an Act of Parliament to enable them to acquire the hospital building for the purpose of railway extension. The negotiations with the railway company occupied more than a year, and at length on Jan. 30th, 1862, the Council was informed that the premises must be given up in twenty-eight days. The enforced search for new premises finally led to a temporary amalgamation, on July 30th, of the Spinal Hospital with the Great Northern, and on Oct. 9th the in-patients were removed to the wards of the Spinal Hospital at 84, Portland-road, the out-patients being at the same time provided with temporary accommodation at 286, Pentonville-road, from which place they were again removed, in February, 1863, to 294, Pentonville-road. This arrangement was found unsuitable and unsatisfactory for the permanent requirements of the hospital, and after a long search and lengthy preliminary negotiations it was decided to purchase Pembroke Villa, Caledonian-road, the in-patients being removed there on Jan. 6th, 1864. In order to secure additional accommodation the adjoining premises were from time to time purchased, and during the next twenty years the work was carried on here under great difficulties. With this history is intimately associated the name of Dr. Cholmeley, who has justly been called the 'Father' of the hospital, and who, during thirty-eight years, unostentatiously but freely gave his services and his means at crises when the committee were face to face with threatening failure. His was the hand ever ready to help when help was most wanted. His *foundling* was often *ailing*, but he relieved its infirmities and restored its vigour. It would be the basest ingratitude to allow these valuable and long-continued services to pass unnoticed among the host of good deeds done in silence which are too soon lost to view in the mists of a fast-retreating past.

"In the year 1882 a movement was started to provide additional hospital accommodation in North London, there being then but one hospital bed for each 25,000 of the population. It was at first proposed to erect a new building to be called the 'Central Hospital for North London,' but after various public meetings had been held this scheme was abandoned in favour of one for amalgamating the proposed new hospital with the already existing Great Northern, and thus by one institution to be named the 'Great Northern Central Hospital' to endeavour to meet the lamentable lack of hospital accommodation for the poor of the district. A suitable site was obtained in the Holloway-road and a portion of the hospital erected, consisting of three wards capable of accommodating in all seventy-two in-patients. An out-patient department, by no means the least useful part of a hospital, has also been built."

The following is from the pen of Mr. C. B. Lockwood, one of his colleagues, and well expresses the esteem in which he

Digitized by Google

was held by those with whom he worked: "Dr. Cholmeley was a senior member of his profession and the senior physician to the Great Northern Central Hospital, when, fifteen years ago, the writer became one of his colleagues. Although so many years have passed, the simple, unaffected kindness and the gentle courtesy of his reception by Dr. Cholmeley have never faded from his memory. A deeper knowledge of Dr. Cholmeley's character increased the respect and regard which were his due. Very patient and forbearing, he either spoke well of others or was silent. The affection of his colleagues was deep and sincere and was the highest tribute to his upright and blameless life. He was the courteous advocate of patience and forbearance and the never-failing peacemaker. In council such qualities as these, being combined with steadfastness and judgment, made his opinion prevail where others would have failed. In his absence many a proposal was deferred or altered lest it should cause him a moment's pain or regret. Goodness and amiability are at times synonymous with weakness, but this was not so with Dr. Cholmeley. He was accustomed when he disagreed to form an independent opinion supported by well-chosen and temperate arguments and with knowledge and experience gathered in the course of a long and laborious lifetime. Moreover, any argument he advanced carried additional weight because none ever dreamt of questioning his absolute sincerity and truthfulness. It was fully recognised that all he did or thought was prompted by devotion to the hospital which he loved so well, and for which he had done so much, and by the most honourable and loyal feeling towards his colleagues. He possessed, too, a quiet dignity of manner which at once commanded respect. But this carried with it no feeling of constraint, for his eyes shone with a most kindly light, and a very pleasant smile flickered around his lips to tell the least observant that he was humane and sympathetic. His memory will long dwell in the minds of his colleagues and be for them a standard of upright and honourable conduct, and an example of all the virtues which made a good colleague and a sincere friend."

These words are a heartfelt and eloquent estimate of one who was always in the old and fullest sense of the word a gentleman. One other point we may mention and that is the endowment of a bed upon July 15th, 1895, in Dr. Cholmeley's honour by the Ladies' Association of the hospital. Over the bed was placed the following inscription: "The Cholmeley Bed, endowed, through the Ladies' Association, in loving appreciation of many years' devoted and unselfish labour rendered by Dr. Cholmeley to the sick and suffering both as physician to the hospital (of which he was one of the founders) and as honorary treasurer to the Ladies' Association."

The funeral took place upon June 23rd, at St. John's, Ladbroke Grove, and besides various members of the family there were present: Dr. Beevor, Dr. Clifford Beale, Dr. Blandford, Dr. Burnett, Dr. Cook, Dr. Maurice Davies, Dr. Morison, Dr. Ogle, Dr. Symes Thompson, Mr. Peyton Beale, Mr. John Gay, Mr. J. H. Macready, Mr. E. C. Hulme, Mr. W. R. Stewart, Mr. Glenton Kerr, secretary of the Great Northern Hospital, and a large number of patients both well-to-do and poor. So passes one who was gentle, honourable and upright, who spared neither time, money, nor labour in the service of his fellow men. Unobtrusive and modest in all that he did, his memory will ever be kept green by the abiding presence of that house established for the relief of pain and sickness, the Great Northern Hospital.

SAMUEL HOLDSWORTH, M.D. PISA, M.R.C.P. LOND., M.R.C.S. ENG., L.S.A., J.P.

DR. HOLDSWORTH of Wakefield, who died on June 13th at his residence in that city, occupied a prominent position in the West Riding of Yorkshire as a philanthropist and public man. His medical career commenced more than sixty years ago, when he became pupil to the late Dr. Bennett of Wakefield, and he subsequently studied at Guy's and St. Thomas's Hospitals and in Edinburgh and Paris. In 1835 he became qualified as M.R.C.S. Eng. and L.S.A., and in 1839 he graduated as M.D. at Pisa; in 1859 he became a Member of the Royal College of Physicians of London. Dr. Holdsworth was engaged in active practice for only about five or six years, but he was for about thirty-eight years honorary physician to the Clayton Hospital at Wakefield, and he devoted himself assiduously to public duties of many kinds. In 1862 he was elected to the Wakefield town council, and he was three times mayor—in 1862, 1863, and 1868. He was also a Justice of the Peace for Wakefield and for the West Riding, a member of the West Riding county council, and steward of the West Riding Medical Charitable Society. Dr. Holdsworth was an enthusiastic advocate of temperance principles; he was eighty-two years of age, and leaves a widow and family, by whom, as well as by a large circle of friends, he will long be held in affectionate remembrance.

THE BATTLE OF THE CLUBS.—XXXIV.[1]

(FROM OUR SPECIAL COMMISSIONER.)

(*Continued from p. 1756.*)

LEEDS: CLUB PATIENTS AT THE INFIRMARY.—FAILURE OF FORMER EFFORTS TO CONTROL CLUB WORK.—MALINGERING.—METHODS OF COMPETITION.—"SIXPENNY AND SHILLING DOCTORS."—"ONE MARK" VACCINATION.

THE position of affairs at Leeds is scarcely better than at Derby, with this difference, however, that most of the medical men with whom I discussed the matter were more anxious to take action, though none had ventured to move in the matter. The Leeds and West Riding Medico-Chirurgical Society might take the initiative. It is composed of three honorary life members, 104 Leeds members, 191 county members, and eight honorary annual members. There are consequently 306 members in all, and the society has a small balance in hand. This would more than suffice to convoke a general meeting of the whole profession for the purpose of founding a union to deal exclusively with economical and ethical questions. Such an effort is very necessary, for the profession has fallen to a low ebb at Leeds. The medical men undersell each other just as if they were rival tradesmen, losing the sense of professional dignity in the ardour of the struggle. Some will take club patients at almost any price and make it pay by employing unqualified assistants to do the work. Then when they have any really troublesome patient they send him to the hospital. The situation is somewhat complicated by the great popularity and high reputation of the Leeds Infirmary. A number of workmen, though they are members of benefit societies or clubs, prefer going to the infirmary, and thus do not call in their club medical officer. They even ask at the infirmary for medical certificates so that they claim the sick allowance from their clubs. This is evidently an abuse of the hospital, since these men have paid for medical attendance by subscribing to a benefit society or to a medical aid association. But it has been

calculated that the cost of out-patients at the infirmary does not exceed an average of 1*s.* 3½*d.* per patient. It would be more trouble to eliminate these cases than to treat them. The economy on 1000 cases would amount to about £65. As the working classes subscribe liberally to the infirmary it would not be worth while for this institution to render itself unpopular for the sake of effecting so small a saving. Nor would the economy cover the cost in time and trouble of carrying out such a reform. On the other hand, this simply means that a great deal of the club practice has to be supplemented by the better and gratuitous care bestowed on the out-patients at the infirmary. Surely this state of things is sufficient to show how urgent is the necessity of a general reform in the whole system of contract work and club practice.

A great deal was said during my various interviews with medical men doing a large club practice about young medical men newly arrived in the town. The position of the latter is often so desperate that they gladly accept club members for 2*s.* 6*d.* a year, for whom the elder practitioners have been in the habit of receiving 4*s.* Sometimes a father wishes to resign his club practice in favour of a son. The club shows its gratitude to their old medical man by accepting the services of his son, but profits by the opportunity to enforce a very much reduced rate of payment. Twenty-five years ago the clubs only paid 2*s.* 6*d.* The medical men then held several meetings and agreed not to accept less than 4*s.* for new societies or when a new medical man was appointed to an old society. In a word, the resolution was not to have a retrospective action; existing agreements were not to be altered. It was, therefore, but a partial reform. For some years this principle was maintained, but in the course of time new men arrived who knew nothing about it and accepted less. Thus it is evident that something more than a temporary union is required. It is not only necessary to unite and establish a rule, but there must be a permanent executive or vigilant committee to see that the whole of the profession is kept well informed as to the conditions established in the district. The moment a new practitioner appears a deputation should wait upon him, explain what are the conditions established, invite him to conform with these rules and join the union. All new arrivals should also be warned as to the consequences that will ensue if he should elect to set himself in opposition to the decisions of the profession and seek to compete unfairly against his colleagues.

Many complaints were made to me of the manner in which club medical officers were made to appear before their committees to answer trivial and unjustifiable charges. Some committees take a special delight in "badgering" their medical man, and complaints are frequent when a medical officer does not readily lend himself to malingering. One amusing case was described to me where, however, the medical man got the better of the patient. A man was constantly claiming his sick allowance on the ground that he was so crippled by rheumatism that he could not work. The way he entered the surgery was a masterpiece of good acting. It was astonishing how a man in such evident pain had been able to come out at all. Knowing the direction which the patient was likely to take on leaving the surgery, the medical man, seizing his hat, went down some by-streets and came upon him at a little distance. He already seemed to be much better and walked with less difficulty. Concealing himself, the medical man followed till the patient was still further away and in a part of the town where he was not known. Here the patient began to walk along with an easy elastic step, smoking a cigar and thoroughly enjoying himself. A few days later the same man appeared at the surgery complaining that he was no better and could hardly crawl along. The medical man with grave face examined him carefully, said it was very serious, ordered him home and to bed, promising to call upon him shortly. Much to his annoyance the malingerer went to bed and managed to present a pitiable aspect when the medical man called. The officer on his side professed to be much alarmed at the serious aspect of the case and forthwith proceeded to apply the actual cautery. The patient, of course, howled lugubriously. He was caught in his own trap and now really suffered where he had only pretended. He ominously never returned to consult the club medical officer, but at the earliest opportunity joined another club. When questioned as to the cause of this defection the medical officer told the whole story, with the result that the other club was warned as to the character of the new member they had acquired. The malingerer was not a little disconcerted when, on consulting his new club medical officer, the latter smilingly suggested the actual cautery as the most effective remedy. It is needless to add that for this one malingerer who was skilfully detected and punished there are many who succeed in fully deceiving their medical officer and are thus able to defraud their club by obtaining sick pay when they are more idle than ill.

In one district of Leeds there were four medical men who did nearly the whole of the club practice for that neighbourhood. These four medical men met and agreed that under no circumstances would they accept less than 4*s.* per annum, and they adhered to this compact. But one of these four medical men brought his two sons into the district. They opened surgeries, one at one end and the other at the other end of this quarter of the town. They, of course, were not pledged to the 4*s.* minimum and by accepting less obtained a great number of the patients whom the old-established practitioners had been in the habit of attending. Here were four medical men. If they had all belonged to a union then there would have been protests, not from three medical men, but from about 300 medical men and with a well-organised union every medical man in the town and neighbourhood would have known immediately what had occurred.

At Leeds, as elsewhere, there are great complaints about the juveniles. Many societies paying 4*s.* a year for adults form lodges of juveniles at 2*s.* a year. The feeling is that as juveniles give more trouble the sum paid should be at least as much as that given for the adults. While, however, some medical men have resigned their position, giving up the adults at 4*s.* so as not to be encumbered with the juveniles at 2*s.*, other medical men have accepted adults and juveniles together at 2*s.* 6*d.* each. Here, again, we find an illustration of the evil effects of competition unrestrained by such professional regulations that a union could establish. There is also a grievance against the London and Manchester Assurance Company. It is said to place its subscribers on the lists of its medical officers without any medical examination; thus many unhealthy persons are insured and have to be attended constantly, though they only pay 4*s.* a year. If a child is assured it is generally an ailing child. One medical officer related to me that when he first came to Leeds he joined the London and Manchester Assurance Company thinking that it was a charity, but he soon found that the canvassers of this company called on his patients and persuaded them to insure their lives, by which means they would secure the services of the same medical man and have to pay only 1*d.* a week. Then he discovered that a number of well-to-do people belonged to the company and expected to receive medical attendance for 4*s.* a year. Some of these wealthy people had sufficient sense of shame to assume false names. On other occasions persons who were subscribers to the assurance company came from another district. The medical officer is apt to mistake these new arrivals for private patients. My informant had attended one such patient for a year. He seemed to be in affluent circumstances, so the medical officer sent in a bill for £22; he received just 4s. The affluent patient was a subscriber to the London and Manchester Assurance Company, but had forgotten to mention the circumstance when sending for the medical officer of the company. Many publicans and other tradesmen who enjoy incomes of from £300 to £400 a year were on the list of this medical officer's club or insurance company patients, and only paid him 4*s.* a year for medical attendance and medicine. Some of these club patients are more difficult to please and more exacting than private patients who pay full fees. But it is not only club practice that reduces the earnings of medical men; there are a great number of "sixpenny doctors" and "shilling doctors" at Leeds, some of whom even offer to vaccinate for 6*d.* and 1*s.*, but many of whom are said to make only one mark. This has the double advantage of economising the calf lymph and reducing the trouble which the child gives to the parents. The parents thus economise in money and in the worry that a child suffering with several pustules occasions. People do not realise the risk that they run. In this respect it is only necessary, for instance, to recall the statistical evidence given by Mr. Marson on 6000 post-vaccinated small-pox cases. He found that among the cases in which one cicatrix was well marked the death-rate was equal to 4·5 per cent., and among the badly marked 12 per cent. On the other hand,

Digitized by Google

among those who had four or more vaccine cicatrices the death-rate was less than 1 per cent.; the death-rate among the unvaccinated was 35·5 per cent. Leeds used to be a well-vaccinated town; now it will soon become a badly vaccinated town. Yet what can be done? So long as the medical man says he has vaccinated the child the law is satisfied, and the less effective the vaccination the greater the satisfaction of ignorant parents. This is a serious question and may bring about a recrudescence of small-pox. Yet who is to act in the matter? The consulting physicians do not suffer from this state of affairs; on the contrary, they are constantly employed by the "sixpenny doctors" and "shilling doctors." A strong consensus of opinion must be brought to bear on both extremes of the social scale. There is the struggling practitioner very low down in the scale who, in the ardour of the competition for existence, loses the sense of professional dignity; and there is the very successful consulting physician, who is so prosperous that he is not affected by, and ignores the troubles of, his less fortunate colleagues. Both the one and the other, those who are at the very top of the ladder and those who are at the bottom of the ladder, have to be exhorted to a better sense of the duty they owe to the profession as a whole.

WEST WILTSHIRE AND SURROUNDING DISTRICTS.

We are pleased to see that organisation and a determination to stand together for their rights are spreading among medical men, as the following instances show, although we regret that in the latter of the two cases the medical men were not perfectly unanimous.

In November last one of the principal benefit societies in the neighbourhood of Freshford proposed a change in its rules under which the medical officers would have been called upon to attend children from one year of age upwards and old people after they had been forced to leave the society for all other purposes but medical aid. In consequence all the medical officers met together and decided to object to these alterations, and the result was that the society withdrew the proposals. In February, 1896, a meeting was called of all the medical men in West Wiltshire and adjoining places, sixty in all, to arrange a conference with the various societies in the district, with a view to obtaining a wage or rental limit. The action of the profession was very much hampered by the refusal of two old-established practitioners to act with their colleagues, as their abstention was well known to those delegates attending the meeting. The conference was held upon May 2nd at Trowbridge. Mr. Charles Flemming said (we take the report of his speech from the *Wiltshire Times*): "The abuse of which they complained was this, that certain persons obtained medical benefits of the friendly societies who did not need them, such persons including tradesmen, retired tradesmen, persons of independent means, and others whose incomes were such that they could well afford to pay a medical man his ordinary charges for attendance. They were thus abusing societies which were originated and had been maintained for the use and benefit of *bonâ-fide* working men and poor persons. The abuse was not so extensive in this part of the country as it was in some parts, but they were going on the principle that a stitch in time saved nine. In addition to being an injury to their societies it was also an injury to the profession, because a medical man could not possibly live by club practice alone; he must have a certain amount of private practice. Then if he depended on private patients as well as club practice, and if his private patients became club patients, he could not continue to practise his profession properly. When a medical man found that his private patients were becoming club patients it was only natural that he should complain, but no medical man had any objection to attend a *bonâ-fide* working man as a club patient. Medical men had to live, and if they were forced to enter into contracts with clubs they might be sure they would endeavour to make those contracts pay if they possibly could. If they had nothing but clubs they must have a very large number to make them pay, and they would thus have to see an enormous number of patients in a day. He did not care whether a man was paid four shillings a year by his patients or whether he was paid a guinea a visit, if he had to attend beyond a certain number of patients in a certain time he could not do it properly; he could not give that careful consideration and that quiet, deliberate examination which were absolutely essential for the proper conduct of medical practice. In medicine, as in other things, if made a business, to put it plainly, especially in practice such as clubs, they might be sure they would get only what they paid for; the value of what they got in the long run would be only the equivalent of the price. They might sweat medical men—as they were sweated in some towns—and they might work them until they became mere machines—machines in which they put a penny in the slot and drew out a bottle of medicine, but they would not get skilled medical attendance and advice. If the abuse which now existed was allowed to go on it would become so extensive that it would disaffect the whole medical profession, and they would lose the men they most wanted and undermine those beneficent institutions which were supported and had been maintained and were maintained for the benefit of the poor working man, and all alike would suffer, whether they were innocent or guilty." Other medical men and a number of representatives of societies spoke, nearly all of whom agreed that the medical men had a grievance which ought to be remedied, only they did not quite see how it was going to be done. Finally the following resolution was unanimously agreed to: "That this meeting takes note of the resolution which has been made by the medical men present at this meeting, that £2 a week wages and £15 a year ratable value be adopted as a limit to prevent persons obtaining medical aid by their friendly societies, who by their position do not require it, and that it be recommended by this meeting to the various friendly societies to consider whether any, and if so what, limit can in future be imposed on the membership of friendly societies so as to accomplish this object." We are glad to see that the tone and temper of the meeting were apparently excellent, and we congratulate Mr. Flemming, who called the meeting together, on the measure of the success he has attained.

LINCOLN MEDICAL PROTECTION FUND.

The following is a list of subscriptions to this fund which have been received in addition to those already announced. We notice the growth of the fund with pleasure:—

THE ASHANTI EXPEDITION.

(BY OUR SPECIAL WAR CORRESPONDENT.)

VI.[1]

AFRICAN REMITTENT FEVER AND ITS SEQUELÆ.

[THE delay in the publication of this last article has been due to the fact that our correspondent has been suffering from the effects of the malaria of which he gives so graphic an account.]

Having already given a history of the African remittent fever, before leaving that subject perhaps it would be as well if I said a few words respecting its sequelæ—as experienced by a great number of those who have apparently

[1] Nos. I., II., III., IV., and V. were published in THE LANCET of April 4th, 11th, and 25th, and May 2nd and 16th, 1896, respectively.

Digitized by Google

recovered from the fever proper to be only again laid low by another complaint that usually succeeds or follows in its wake. First of all there is colic. This complaint is very common amongst those who have suffered from fever, and I question very much if any convalescents from remittent fever of the African type will escape being attacked by colic afterwards unless the greatest care and caution be used. The slightest indiscretion in diet will at once produce it. A change of temperature often, too, brings on colicky symptoms, and so sensible are these patients' bowels of impressions made on the skin that the tenderness would indicate the presence of chronic inflammation or even ulceration of membrane. Diarrhœa is often experienced after fever has entirely passed off; but of all complaints dysentery is the one that has carried off most patients. Dysentery may be an immediate sequence of the fever or it may come on months after the fever has passed away. Hepatic disease not infrequently occurs. Post-mortem examinations have not often been made, but when they have been undertaken have generally shown that the peritoneum and its attachments as well as the intestinal tube exhibited a general yellow tinge, the stomach containing from four to five ounces of a yellowish-green fluid. The mucous coat was invariably softened whether fluid were present or not. Livid patches were also observed distributed over the inner surface of the stomach. These pathological appearances were chiefly in evidence near the pylorus. Lesions were also observed in the duodenum, becoming less evident towards the jejunum. The gall-bladder was in most cases distended with bile of the consistence and colour of tar.

THE HOSPITALS EN ROUTE.

Of these there were several—in fact, one at each rest camp; but the principal or larger erections were at Kwissa, Prahsu, Assin-Yankumasi, Mansu, and Cape Coast Castle. Kwissa hospital was a commodious building constructed of bamboo and thatched with leaves of that plant. It occupied a good, healthy position. There was an excellent supply of wholesome water. The rooms were both lofty and well ventilated, and the latrines, placed at a convenient distance in the rear of the building, were always kept clean and well supplied with disinfectants.

PRAHSU HOSPITAL.

When I first arrived at this place I found a building had already been put up by the colonial authorities, constructed, as they usually are, of cut bamboos. It was about seventy feet by thirty feet and situated at the entrance or south-eastern extremity of the camp, surrounded by dirty, foul-smelling native huts, and not too far removed from some swampy ground. However, this latter could scarcely be avoided considering Prahsu surroundings generally; but the native abominations, with the pigs and fowls and dirty, foul-smelling heaps, might certainly have been done away with before the officials commenced to erect a hospital for the reception of the wounded and the sick. These precautions were not taken, and only on the arrival of our own medical officers, notably Surgeon-Lieutenant-Colonel Blennerhassett and his staff of surgeons and orderlies, were the native huts demolished and the refuse heaps and other pestiferous abominations swept off the surface of the ground. Further than this, the native hospital was soon condemned and a newer and much more suitable one erected in its stead. On my return from the other side of the Prah I was astonished to see what an amount of sanitary improvements had been carried out by Surgeon-Lieutenant-Colonel Blennerhassett, and how painstaking he had been in improving the general surroundings of this swampy place. Not only were the patients well supplied with fresh bread and excellent sweetened and unsweetened milk, but by an admirable arrangement ice manufactured at

Cape Coast Castle was brought up twice a week or oftener to Prahsu.

HOSPITAL AT ASSIN-YANKUMASI.

On my journey up this hospital was in an incomplete state; erected, like that of Prahsu, under the supervision of the colonial authorities, it was intended, I believe, only for the use of native troops, but was afterwards used by our own officers and men. It was a long bamboo erection divided into three compartments; one of these was devoted to a sort of drug store and serving-out room, the central portion was used as an officers' and the remaining part devoted to sick privates' quarters, the separation betwixt these compartments being only effected by split bamboos. The covering overhead was composed of layers of bamboo leaves, but so thinly laid on and so defective in some parts that daylight could easily be seen through the roof, whilst rain and even large drops of dew fell upon the blankets of the sick who were destined to pass a night under such a defective kind of roof. The *locale* chosen for the hospital was, moreover, a very questionable one from a sanitary standpoint—nearly at the bottom of a small hill on the top of which the natives had wisely erected their own huts. All drainage necessarily flowed to this part; the bush having recently been cut lay (by pace measurement) in festering heaps just nine yards from where the sick were supposed to lie. A latrine at the rear of the hospital and abutting closely on the rotting heaps of vegetable material added to the general bad arrangements of this place. To these discomforts must be added the presence of numerous black ants, and on one occasion these creatures in myriads stormed the place and veritably (I am not exaggerating) drove patients and attendants out of it.

Assin-Yankumasi could accommodate 500 troops in barracks, with hospital beds for the same (about twenty cases). They had some ten or twelve stretchers for use, but had no bed-pan or proper commode, an old oil tin being used for that purpose. The elevation of the roof of the building is fairly lofty, but too much slope is given, consequently the sides are very low and there is an insufficiency of windows and ventilating spaces throughout. The officers' apartments were both dark and gloomy, the partitions before referred to preventing a free circulation of air. Patients suffering from diarrhœa had to go outside to the latrines, even at night, there being nothing for their use inside.

HOSPITAL AT MANSU.

This hospital was a very good one. The site was better chosen and its construction was a decided improvement on that I have just referred to. The water collected from the river gave good results with the chemical tests employed, but, of course, was all filtered before being given to the patients. As I spent a day or two in this hospital I can only say, as all the other patients told me, that every attention was paid by those who controlled affairs at this rest station. I believe it is in contemplation to erect a permanent building at this place for the use of officials and Haussas going to and returning from Kumasi. Fruit was procurable and mutton as well; a few fowls were obtained here for the use of the sick at the hospital. An excellent hospital train service was established betwixt this place and Cape Coast Castle. The same admirable transport for sick or wounded was subsequently extended to Prahsu, and latterly to even more remote stations beyond the river, the bearer company, with hospital cots, being in charge of a Medical Staff Corps official up and down. This was a regularly timed service.

CONNOR'S HILL HOSPITAL.

After leaving Mansu, bound for the coast, there was no hospital of importance till that at the base on Connor's Hill, Cape Coast Castle, certainly the best *en route*. Its site was admirably chosen, the wooden houses, hospital tents, wards, and large water-tanks being placed on the summit of Connor's Hill, some half a mile or so to the N.N.E. of the town. (Fig. 2.) The erections have been in existence some years and were formerly built for the accommodation of coloured troops, and when they left the tenements were utilised as a sort of public school, it being considered by the teaching authorities expedient to afford the children a good healthy walk both night and morning before commencing and on ending their various studies. On the breaking out of the recent campaign the colonial authorities, being possessed already of an excellent stone-built native hospital in the town, offered these habitations to the military authorities, who very wisely accepted the offer, and under medical direction have turned these quondam barracks and class-rooms into what they are at present, the wards, dwellings, and offices of a very good military hospital for white troops. The series of wooden-built houses, painted white with glass windows, (vide Fig. 2) occupy a position on the very top of a hill composed of disintegrated lava and gneiss soil, with a graduated fall on all sides. The prevailing winds are westerly, the elevation being about 200 feet above sea level. All the buildings, &c., are stayed with bamboos in case of tornadoes coming on. Water here is obtained from the Castle and carefully stored in large galvanised metal tanks capable of holding 10,000 gallons. On all sides aloes, pines, and oleander trees are seen growing to perfection. There are three separate, well-built, very carefully cleaned latrines situated just under the brow on the leeward side of the hill. These latrines were regularly filled in with earth when necessity arose for their abandonment. The officers' sick quarters were models of comfort and neatness. The rooms, as shown on the right side of the illustration, were about 20 ft. long and 15 ft. wide, floored with wood. Each room possesses a nice iron bedstead with excellent bedding and protected by mosquito curtains. From the windows can be obtained a charming view of the sea. In each apartment there are a table, two easy-chairs, and chest of drawers. Just off the room is the bath place as well as an earth-closet. I should also say there are fireplaces in each apartment. The ventilation throughout is all that could be desired; the temperature of the rooms during the heat of the day seldom exceeded 88° F. during my stay on Connor's-hill. The men's wards were, of course, much longer and slightly wider, and offered splendid accommodation for the sick and wounded. They were kept scrupulously clean by the hospital attendants. Connor's-hill Hospital is equipped for 75 beds, including five for officers. To Surgeon-Major Wilson's careful supervision the excellent arrangements at this hospital must be attributed. The admissions up to Jan. 28th, 1896, were as follows: 130 white troops, 12 white officers, 89 coloured troops, and no coloured officers. There had been one death due to remittent fever. The temperature in this case rose to 109·2° and the patient died after being under treatment for one week. I learnt that the late Prince Henry of Battenberg was in this hospital two days prior to his embarkation. In closing my report on the hospitals and their accommodation I can only add my very humble testimony to the general efficiency observable throughout, as well as speak of the great care and attention I have seen bestowed by the Military Medical Staff on all who have unfortunately been compelled to solicit its assistance.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Ladies' Charity and Lying-in Hospital.

THE dispute at this charity is now practically settled. At the special meeting of the subscribers held to-day alterations were made in the laws in accordance with the terms laid down by the late staff and the profession. Two points were insisted on by the latter: firstly, that the medical officer on duty should have sole and entire charge of all patients in the hospital, without any ambiguity whatever; and, secondly, that three representatives of the medical board should have seats on the board of management. These points have been conceded in their entirety by the general body of subscribers, thus rendering the victory of the late staff complete. It had been rumoured that some members of the board of management had stated that they would resist the re-election of some members of the late staff, but after the intimation from Mr. Mitchell Banks at the special meeting to-day, that if that were the case the hospital will be left for a further indefinite period without a staff, it became certain that the board of management would not care to try another fall with the profession. The late staff have all been asked to resume their offices. It is a pity that the decision arrived at to-day was not attained months since, whereby would have been avoided all the unpleasant issues which have had the effect not only of impairing the good name but also the usefulness of

Digitized by Google

the charity. Not only have the admissions to the hospital been reduced in number owing to the non-existence of a medical staff, but also the classes of instruction to the candidates for the post of midwife have had to be suspended, which has proved a great hardship to them. They have to thank the board of management for the position in which they now find themselves, as the fault has certainly not rested with the members of the late staff. The medical profession here are to be congratulated on the firm attitude they have all along maintained in so loyally supporting the late staff in their uphill fight with this autocratic board of management.

Supply of Hot Water in Public Streets.

The Watch Committee have granted permission to the Hot-water Supply Syndicate of London to construct experimentally three columns, connected with the gas lamps in the streets, by means of which it is proposed to supply the public with hot water on the penny-in-the-slot principle. The syndicate have a patent contrivance for utilising the waste heat from the gas of public lamps for the purpose of instantaneously heating water. During the hours of street lighting water is heated by means of a coil of metal pipe with the flame of the gas. An annular tank is also fixed above the flame and provides a store of warm water ready to be transferred through the hot coil. In the day time, when the street lamps are not lighted, only a small flash light is continuously maintained in the lamp. It is proposed to supply the hot water at a halfpenny per gallon, and when the coin is put into the slot in the daytime the flash light is turned on at full force for a sufficiently long period to heat one gallon of water, which is discharged from a cock at the base of the column. The water can be instantaneously heated in these columns up to 194°, which is hot enough for all domestic purposes other than making tea and such like. If the water could be delivered at the boiling heat it would prove a boon to those desirous of making tea or coffee when the domestic fires were allowed to go out in hot weather.

New School of Pharmacy.

A school of pharmacy has now been added to the other departments of University College. From the names of the college professors and other lecturers appearing on its prospectus there is every prospect of it proving a success. Instruction will be given adapted to the requirements of candidates preparing for the minor and major examinations of the Pharmaceutical Society of Great Britain. A student before entering the classes must have passed the first examination of the Pharmaceutical Society, or an examination accepted in lieu of the same by the society. During the academic year (October to July) there will be a junior and a senior course of instruction in each subject of the curriculum. The first or junior courses include the subject-matter of the schedule for the minor or qualifying examination. A student who enters the school in October may present himself for the minor examination in April. The second or senior courses include the subject matter of the schedule for the Major Examination of the Pharmaceutical Society. A student who enters the school in October and passes the minor examination in April may pass the major examination in July. All students are strongly advised to enter the school at the beginning of the winter session in October. All registered students are allowed to use the College library and reading-room. There are also well-equipped museums of chemistry, botany, and materia medica, which contain a fine herbarium and a collection of drugs from the Pharmaceutical Society. Students are enrolled by the Dean of the Medical Faculty, University College, Liverpool.

June 23rd.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The First Hospital Saturday in Bristol.

BRISTOL Hospital Saturday was inaugurated on June 13th, although there is no doubt that for the future it will be an annual event. Everything fortunately contributed to its success. The weather was fine all day. The arrangements for the street collections were excellent. Stations were selected all over the city for placing a chair and a table at which a lady should sit, and offers were made of the use of rooms and offices had the weather been unfavourable. The house-to-house collections by the ladies' auxiliary amounted to over £400 and the street collections have up to the present totalled £460, but a few other boxes have yet to be returned. As the honorary secretary of this fund has recently stated it is useless to compare the Bristol Hospital Saturday with that at London or Birmingham, for at these two places the employers of manufacturing industries, &c., make collections from week to week all the year round for the Hospital Saturday Fund, and the sum obtained is thrown into the street collections on the day that may be appointed for Hospital Saturday. In Bristol this is not done, so comparisons cannot be made. The Bristol factories make collections during the year and forward the sum to the institutions. In 1895 the working men of Bristol contributed £4000 to the medical charities of that city.

The Recent Outbreak of Small-pox in Glamorganshire.

Dr. Williams, the medical officer of health for Glamorganshire, reports that 160 cases of small-pox have occurred in Glamorganshire during the current year, but at present the disease is on the wane. He adds that in districts which had provided isolation accommodation the disease did not spread to any extent. At Bridgend no accommodation whatever had been provided by the sanitary authority, with the consequence that 18 cases occurred. The expense accruing to the Bridgend authority by the prevalence of small-pox in their district would have been sufficient to defray the cost of providing the permanent isolation hospital which is about to be erected by order of the county council. Dr. Williams, in concluding his report, says that isolation and re-vaccination were rigidly exercised wherever possible, but that the threatened prevalence of small-pox in the county, which was the means of providing two additional small-pox hospitals, clearly proved that it is safer and far more economical to have every means and appliances always in readiness.

Crime in Gloucestershire in 1895—a Decrease.

At a meeting of the Gloucestershire Joint Committee to be held at Gloucester on June 23rd, the Chief Constable (Admiral Christian) will furnish a return as to the crime in the county during 1895. Under the head of indictable offences the crimes reported to the police numbered 629, a decrease of 116 as compared with the return for the preceding year. The number of persons apprehended and summoned for these offences was 597 (a decrease of 186); and of these 159 were tried summarily and discharged, 264 were convicted, 86 were committed for trial and sent to prison, 23 were bailed for trial, and 65 were otherwise disposed of. For non-indictable offences, 1253 persons were apprehended, and 5038 summoned, a decrease of 18 compared with 1894. The increase in the number of cases of drunkenness was 13.

A Curious Vaccination Case from Gloucester.

On June 13th at Gloucester Mrs. J. Bryant of Tuffley Court, was summoned for neglecting to have three children vaccinated. Defendant said she objected to the present system of performing the operation, which she said was inoculation not vaccination. She wrote to Mr. W. Washbourn, M.R.C.S., to come and vaccinate her children from cow-lymph. She showed him a cow that had cow-pox, but he would not undertake to draw lymph from the teats and vaccinate the children. She added that she would not consent to her children being inoculated with calf lymph, as calves never had cow-pox, that she could perform the operation and that all the men on her farm had been vaccinated in the process of milking from the lymph of the cow getting into cracks in their hands. The clerk to the magistrate pointed out that the law called the system to which defendant objected "vaccination." Defendant asked if the requirements of the law would be fulfilled if she performed the operation herself, and the chairman of the magistrates said that if she obtained a medical certificate to the effect that it was properly done that would doubtless be sufficient. The usual order to have the children vaccinated was made, with costs.

The Sanitary Condition of Glamorganshire.

At the quarterly meeting of the sanitary committee of the Glamorganshire County Council, Dr. Williams, the medical officer of health, gave an exhaustive report upon the sanitary condition of the county; he stated that the river Ogmore, which he had recently inspected, was the main sewer for Maesteg, Garw, Ogmore, Bridgend, etc., and until these authorities were compelled to provide for the disposal of the sewage, the foul condition of the river would not be materially improved. The condition of the river was foul, the stench unbearable and conducive to ill-health and fever among the inhabitants. He also added that on the occasion of his first inspection of the district three years ago he heard just the same tales

Digitized by Google

as on the present occasion: Caerphilly and Pwllypant were to be provided with a better water-supply, Nantgarw, Glanllyn, Taff's Well, &c., were to be connected with the main sewer, the pollution of rivers was to be stopped, and a host of other promises were made, but not kept. When complaints were made by the committee the answer was that the district council was doing its best. Dr. Williams is of opinion that the district council has not fulfilled its promises, and he instances a communication received in March, 1895, from the Llandaff and Dinas Powis authority in respect to connecting Tongwynlais with their sewer. Since that time Tongwynlais has been a hot-bed of fever, and twenty out of the twenty-three cases of typhoid fever notified in the whole district in 1895 occurred there. Dr. Williams adds that this is not to be wondered at, as there is everything ready for the spread of disease.

The Nursing Arrangements at the Cardiff Infirmary.

There has recently been a considerable falling off in the receipts from the private nursing department of the Cardiff Infirmary, for in 1893 the gross earnings of the nurses was £1060 and the profit £574; in 1894 the earnings were £841 and profits £333; and in 1895 £696 was taken and the profits were only £200. With a view to encouraging the nurses to remain for a longer period at the infirmary it was decided at a meeting of the Cardiff Infirmary general committee, held on June 11th, that from July 1st next a trial for six months should be given to the following scheme—viz., that during the second year nurses should receive a salary of £16, the third year £20, the fourth year £25 and 5 per cent. of their earnings if sent out for private nursing, the fifth year £25 and 10 per cent. of the private nursing fees, the sixth year £28 and 15 per cent. of the private nursing fees, and during the seventh year £30 and 15 per cent. of these fees. This seems to be a good plan, and it will doubtless have the desired effect upon the nursing staff of this institution.

Estate of the late Mr. Charles Highett.

The will of the late Mr. Charles Highett, M.R.C.P. Edin., L.S.A. Lond., formerly of Field House, Montpelier, Bristol, who died on April 20th, has been proved in the Bristol District Registry of the Court of Probate. The gross value of the personal estate is £63,737 15*s.* 9*d.* and the net value £63,650 14*s.* 3*d.*

June 24th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Complimentary Dinner to Dr. G. H. Philipson.

A DINNER was given last week to Dr. G. H. Philipson by the honorary physicians and surgeons of the Royal Infirmary, Newcastle-upon-Tyne, upon his retirement from the position of physician to the infirmary. All the staff attended. In replying to the toast of the evening—"The Health of Dr. Philipson"—which was proposed by Dr. Arnison, the senior surgeon to the infirmary and the oldest member of the staff—Dr. Philipson returned thanks in very feeling terms, the wrench he was experiencing in terminating his long services being painfully apparent to his colleagues. The rule under which an honorary officer is compelled to retire at the age of sixty years may be of advantage to those seeking promotion—it obviously is so, but it is difficult to understand why a physician should be called upon to retire at the age of sixty, whilst statesmen, soldiers, bishops and judges are allowed to hold office till they are ten years and, indeed, often more than ten years older. The present Master of the Rolls is more than sixty, and there is no more capable or astute judge upon the bench.

Election of Physician to the Royal Infirmary, Newcastle-upon-Tyne.

The selection committee met in the infirmary on Thursday last and appointed Dr. George Redmayne Murray an honorary physician. A few months ago Dr. T. Beattie was appointed pathologist, so that two new officers are now upon the staff. The charity is open to congratulation upon its having secured the services of two such excellent officials and the medical side of the house is materially strengthened by the addition of another member to the teaching staff. Formerly the pathologist was a full physician; under the present arrangement the duties of the pathologist will be discharged by one who is not otherwise engaged at the hospital. Before the selection committee separated the chairman announced that he had received notice of a motion to the effect that it was desirable that two assistant physicians should be added to the staff. At present there are no assistant physicians, although there are four assistant surgeons.

Lieutenant-Colonel Gowans, M.D.

By the resignation of this officer, who has been connected with the 3rd Durham Volunteer Artillery for eleven years, the service has sustained a loss which will be felt for long. Dr. Gowans has been a most active and useful volunteer and leaves a regiment of 400 men in a very flourishing condition. When he was appointed commanding officer there were only 250 men in the corps and it is owing to Dr. Gowans' energy that the number has been increased to 400.

Report of the Medical Officer of Health for Newcastle-upon-Tyne.

In his twenty-third annual report, Dr. H. E. Armstrong, the energetic and able medical officer of health for Newcastle-upon-Tyne, states that the death-rate of the city, for the past year, has been at the rate of 20 per 1000, slightly below that of the average rate in 33 large towns of the United Kingdom. There has been an increase in the number of marriages, and in the deaths from zymotic disease. Scarlet fever, diphtheria, and typhoid fever have been more fatal than in 1894, but there have been no deaths from typhus or from small-pox. The deaths of infants under one year of age, show an increase of 216 over those of 1894, and 44 uncertified deaths were registered against 37 in the preceding year. 27,628 inspections of tenement property were made during the year and 197 cases of nuisance were heard before the magistrates. The work under the Food and Drugs Act has been more than double that of 1894.

Newcastle Lifeboat Saturday.

A very successful demonstration in connexion with the Lifeboat Fund was held in Newcastle on June 13th. The day was fine and the streets through which the procession passed could hardly have been more crowded. The mayor and mayoress, the sheriff, and other city dignitaries took part in the demonstrations, and among the carriages were three filled with infirmary nurses in their uniforms, who begged persistently and successfully. Mr. John Burdon is chairman of the Saturday Lifeboat Committee, and much of the success of the movement here is due to his zeal. As the result of Saturday's proceedings a goodly sum of money has been added to the funds of the Royal Lifeboat Institution. Mr. John Burdon is a busy medical man in Newcastle, not too busy however to identify himself with this and many other similarly useful movements having for their object the safety and well-being of the people.

Newcastle upon-Tyne, June 22nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University Court.

AT the last meeting of the Edinburgh University Court it was intimated that a new Vans Dunlop scholarship had been instituted in Pathology and Medical Jurisprudence, and that a Pattison bursary had been assigned to Clinical Surgery.

The Sanitary Inspectors' Congress.

The Sanitary Inspectors' Association of Scotland held its annual congress in Oban on Friday of last week. The Association was welcomed by the Provost and various papers of interest were contributed by members.

The Death of Dr. C. M. Campbell.

Dr. C. M. Campbell, formerly medical superintendent of Murthly Lunatic Asylum, died in Edinburgh on Saturday. He was a young man, having graduated in medicine at Edinburgh in 1878. Before his appointment to Murthly he had served in the Durham County Asylum, the Friends' Retreat in York, and the West Riding Asylum. He had to resign his position at Murthly owing to ill-health. One of the features of his tenure of office at Murthly was the establishment of an evening school of which the Commissioners in Lunacy spoke highly in their reports.

British Medical Association.

It is understood that steps are being taken in Edinburgh

Digitized by Google

with a view to invite the British Medical Association to hold its annual meeting there in 1898.

Glasgow University.

The University Court has decided to recognise Dr. R. M. Buchanan and Dr. J. Edgar as extra-academical lecturers, whose courses at Anderson's College Medical School on medical jurisprudence and midwifery respectively qualify for graduation in medicine in the University. Mr. Jno. C. Willis, M.A., has resigned his appointment as Demonstrator of Botany in the University, and he is to be succeeded by Mr. Wm. H. Lang, B.Sc. The lecturers in the faculties of Arts and Medicine at Queen Margaret College have been re-appointed for another year. The final examinations for graduation in medicine and surgery commenced last week, and the clinical portion of the examination will be continued until July 3rd. On that date the written examinations will commence and those in turn will be followed by the oral and practical lists. The results will be published about July 21st and the graduation ceremony is announced for the 23rd. The number of candidates who have entered for the examination is 132, including nine women candidates from Queen Margaret College. The session which is just concluding will be memorable by reason of the Kelvin jubilee celebrations. The entire functions were altogether successful, the arrangements in every respect being admirable. At the banquet given in honour of Lord Kelvin on the 16th inst. a telegram of congratulation from the Queen was read, and amongst the speakers were the Italian Ambassador, Lord Rayleigh, Sir Joseph Lister, and Professor Gairdner. On the following day the excursions on the Firth of Clyde were somewhat interfered with by broken weather, but a determination to make the best of things was everywhere manifest. These festive proceedings, however enjoyable in themselves, do not create an atmosphere favourable to the steady pursuit of work, and both professors and students to some extent feel their disturbing influence. The present week is to see a further academical function—not, however, of a very thrilling type—as the principal and professors have issued invitations to a reception in the Bute Hall for the 26th inst. in connexion with the Pan-Presbyterian Council at present holding its meetings in the city.

Memorial to a Medical Man.

A handsome memorial has recently been erected in the Howard Park, Kilmarnock, to the memory of the late Dr. Marshall, who was in practice in Kilmarnock for forty-two years and died in 1894. The memorial, which consists of a marble statue of Dr. Marshall placed on a carved granite pedestal, was unveiled on the 21st inst. by Professor Gairdner, who delivered an appreciation of the services which for so many years Dr. Marshall had rendered to the town and district. Though unknown in the great world he had lived up to the ideal of a medical man and had made his influence felt on many lives.

The Health of Aberdeen.

Owing to the prevalence chiefly of measles and scarlet fever there were on Friday night of last week 220 patients in the City Hospital, by far the largest number on record. The cases of zymotic diseases reported for week ended Saturday, 20th inst., however, showed a decline in whooping-cough. Measles numbered 14; scarlet fever, 70; diphtheria, 2; typhoid fever, 1; whooping-cough, 22; and erysipelas, 4; total, 113, of whom 53 were removed to City Hospital.

June 23rd, 1896.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The University of Dublin.

A MEETING of the Senate was held on the 19th inst. for the purpose of considering graces sent down by the committee for confirming degrees. The Rev. Dr. Haughton, Senior Proctor, said that he was instructed to inform the Senate that the Provost and Senior Fellows had passed a grace of the house to confer the degree of Doctor of Medicine *honoris causâ* on Sir Willoughby Francis Wade, a distinguished graduate of the University, who occupied a leading position among the medical men of Birmingham and who had made his name famous by his writings on medical subjects. A similar honour in the shape of the degree of Doctor of Science *honoris causâ* was, on the same occasion, conferred on Dr. John Batty Tuke, the distinguished neurologist and the President of the Royal College of Physicians of Edinburgh.

The Transfer of Lunatics from the Belfast Asylum to the Workhouse.

A discussion in reference to this vexed question has taken place between committees of the Belfast Asylum and the board of guardians, and it would seem that Dr. Cuming, who occupied the chair, and other members of the asylum board, when they were considering the claim to have terms agreed upon pursuant to Section 9 of the Lunatic Asylums (Ireland) Act, 1875, for the support of lunatics sent to the workhouse by the asylum authorities, suggested that before making any arrangement the guardians should be able to present to the governors a statement that the inspector of lunatics was satisfied with the accommodation which the guardians provided for the lunatics and that they could not recommend the payment of any money to the guardians until this was done. Dr. Cuming also suggested that their medical officer should have complete control or supervision over the lunatics who were sent from the asylum to the workhouse. The guardians' committee would not concede the latter terms, but agreed that the parties so sent should receive all the care that was rendered necessary by the Acts of Parliament upon the subject. The guardians' committee stated they would be satisfied with the capitation grant made by the Government for the support of lunatics in the asylum, which was stated to be 4*s.* per head per week. The entire subject will be considered at the next meeting of the asylum governors. It would seem that seventy-seven lunatics are in the workhouse who have been sent down from time to time from the asylum, and they have cost the ratepayers on the lowest calculation £6000. It would also appear there are forty-seven lunatics in the workhouse sent down to that place illegally as they did not belong to the Belfast Union, but came from other districts. If this statement, which was made at the last meeting of the Belfast board of guardians (June 16th), be confirmed then all these forty-seven lunatics should not have been sent from the asylum to the Belfast workhouse, but to the original unions from whence they came.

Belfast: the Coroner's Salary.

At an adjourned meeting of the City Corporation of Belfast in committee on June 22nd it was decided by a majority that the salary attached to the office of coroner of Belfast as it is at present, and as it may be extended, shall be fixed at £650 a year, which shall cover everything except an office to be provided by the council in the new town hall for the transaction of the official business of the coroner.

Poisoning by Carbolic Acid.

An unfortunate case of death from carbolic acid poisoning took place on June 21st in Belfast. It seems that a man, a painter by trade, went to his home on Sunday night after eleven o'clock under the influence of drink, and going upstairs to a bedroom swallowed the contents of a bottle (which he probably thought had whisky or other spirits in it) containing carbolic acid which his mother had bought for sprinkling about the room as a vermin destroyer and had placed on the corner of the mantel-piece. The man died before the medical man, who came at once when summoned, had time to reach the house. The verdict of the jury was death from carbolic acid poison, self-administered by misadventure.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Proceedings at the Académie de Médecine.

THE proceedings at the last meeting of the members of the above-named corporation included the following communications. M. Péan stated that a careful study of the cranial vault has led him to the conclusion that the bones composing the left half are thicker than those of the right, this being in direct opposition to the rule applying to the rest of the skeleton. He also noticed that all the bones of the vault were frequently thickest at the sutures. The thickness of the cranial bones in the healthy differs according to the age, the sex, and the development of the

Digitized by Google

skeleton in general, these variations being also found in the following pathological conditions: rickets, hereditary syphilis, hydrocephalus, idiocy, epilepsy, mental degeneration, &c. It is important to bear the preceding facts in mind in view of a possible trephining operation. M. Lejars reported the case of a woman aged twenty-nine years who, having swallowed half a tumblerful of commercial hydrochloric acid on Jan. 11th, 1896, suffered immediately from intense pain and repeated vomiting of dark blood. Feeding became impossible, all food being rejected as soon as swallowed. Milk in quite small quantities was the only nourishment tolerated. Pyloric stenosis rapidly developed, the stomach being considerably dilated, while any food the patient had taken the previous day, together with a large quantity of black fluid, was got rid of by daily washing out the stomach. Emaciation, however, made great progress and the general condition being highly disquieting supra-umbilical laparotomy was practised on March 12th. The greatly distended stomach presented on its anterior surface yellow cicatricial striæ, the pyloric region being occupied by a dense mass. Gastro-enterostomy was performed, a medium-sized Murphy's button being used. The operation, which was quickly over, was well supported. For the first three days nutritive enemata only were given; on the fourth day an egg, bouillon, and milk were swallowed. The patient was discharged in capital condition at the end of April, having gained 5½ kilogrammes in weight. Since her discharge the appetite has returned and she has eaten abundantly. At present she weighs 58 kilogrammes as against 38 kilogrammes, her weight before the operation. M. Lejars called attention to the following points—viz., the limitation of the burns to the stomach, the œsophagus having curiously enough escaped, and the rapidity of the development of the pyloric stenosis. M. Mouchet of Sens reported a case of double ovariotomy in a young woman three months advanced in pregnancy, the course of which was not interrupted, a healthy child being born at term. M. Marc Sée called attention to a mode of exploration of the abominal viscera, which he terms *exploration hydrostatique*. He stated that when this examination is conducted while the patient is immersed in a warm bath palpation is greatly facilitated, the abdominal parietes offering no resistance even in the obese.

The Health of Paris.

I deem it well from time to time to supply information concerning the sanitary condition of this beautiful city, which is just now looking its best. In a population of 2,424,705 (census of 1891) there died in the twenty-fourth week of the current year 844 persons, a diminution of 72 on the figures of the preceding week and of 80 on the average for the time of year. Epidemic diseases are rare. A noteworthy circumstance is the occurrence of only one death from typhoid fever, as was also the case during the preceding week. Measles caused 16 deaths (average equal 32). Scarlet fever is fairly prevalent (120 cases during the week), but it is of a mild type, having caused only 6 deaths. Small-pox is responsible for one death only (one also for the previous week). Phthisis caused 160 deaths and cancer 57. There were 19 suicides and 17 deaths from violence.

The Rôle of the Spleen in the Defence of the System.

M. Courmont and M. Duffan of Lyons communicated to the Société de Biologie (June 13th) the result of their experimental researches on the part taken by the spleen in defending the economy against the attacks of divers microbes. The animal chosen was the rabbit which supports splenectomy without losing flesh. Injections of the streptococcus pyogenes, staphylococcus pyogenes, and the bacillus pyocyanicus were practised on these splenectomised animals and on normal rabbits. Rabbits splenectomised from two to twenty-five days beforehand were found to be much more sensitive to the bacillus pyocyanicus than their normal companions, the animal dying in a few hours, whereas normal rabbits survived longer or altogether. The staphylococcus kills the prepared animal in ten hours in a dose insufficient to bring about a like result in the normal rabbit or which kills only in a week. When an attenuated sample of a very virulent culture of streptococcus was injected into the splenectomised rabbit, the animal splenectomised only a few days or hours previously resisted always better than the normal rabbit. The splenectomised rabbit may even survive altogether when the culture is still further weakened. It would thus appear that the spleen whilst useful in defending the system against the inroads of the bacillus pyocyanicus and the staphylococcus, is positively mischievous in the struggle against the very virulent or attenuated streptococcus. In both cases a focus of production of phagocytes is suppressed.

The tenth session of the French Surgical Association will meet at the Paris Faculty of Medicine on Monday, Oct. 19th, 1896, under the presidency of M. Terrier. The two undermentioned subjects will be discussed: "Surgical Therapeutics of Club-foot," "Treatment of Genital Prolapsus."

The Prefect of the Seine has recently addressed a circular to medical inspectors of schools calling upon them to supply in addition to the usual certificate of recovery of scholars from diphtheria, another issued by the Bacteriological Service of the City of Paris affirming the absence from the mouths and throats of those same children of Loeffler's bacillus previously to their re-admission to school.

The death is announced at an early age of Dr. Girode, médecin des hôpitaux de Paris. He collaborated with Professor Brouardel and Dr. Gilbert in the publication of an important work on Medicine (Traité de Médecine et de Thérapeutique, 1895), the first chapter of the first volume on Maladies Microbiennes en Général being from his pen.

June 23rd.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The New Manicomio.

THE celebrated lunatic asylum (*manicomio*) in the Trastevere overlooking the Tiber is shortly to be pulled down and a new edifice worthy of the capital and of the progress of medico-psychology is in contemplation. Already the leading alienists of the kingdom are suggesting the lines on which the rehabilitated establishment should be laid, and the Commendatore Azzurri's monograph on the subject is attracting the attention due to his high reputation in hygienic architecture. He is very severe on the present condition of Italian hospitals for the insane. So defective are they in all respects that their reform has passed into the first line of the country's needs. Any "stamberga" (ramshackle building), according to the Commendatore, has hitherto been thought good enough for a madhouse; and if the great Roman one, with its successive improvements and its fine "succursali" (dependent quarters), in the Janiculan, is now inadequate, the fact simply throws into stronger relief the imperfections of those which still retain their mediæval character. "Our poverty, but not our will, consents," is the invariable answer of Italians to such criticisms, and I fear the "money consideration" will make itself felt even in the reconstruction of our Manicomio. The pavilion system has many advocates, but the Commendatore Azzurri, fortifying his own opinion with that of more than one authoritative alienist, is almost vehement in his recommendation of the "manicomio-villaggio" (asylum village). Mainly on the lines of Gheel, it must assume, he urges, features of its own in harmony with local and national conditions. Rome, or rather the Agro Romano, should, he thinks, set the example now as formerly, and, with her splendid choice of healthy sites on the Alban or Sabine uplands, might in a few years furnish Italy with an object-lesson which other provinces would gladly be proud to imitate. It is too much the fashion to think the Gheel precedent as *sui generis* owing its success to circumstances not to be commanded elsewhere. The Commendatore Azzurri indicates how it might (as far as Italy is concerned) be improved upon; and in any case he puts it overwhelmingly *en évidence* that almost any system would be better than that now prevailing in the peninsula and islands.

A Soudanese Fortress in Midsummer.

One of the medical inmates of the stronghold at Kassala writes, under date May 30th, that the heat, continuous and well-nigh insupportable, averages from 50° to 52° C. To secure a consecutive sleep of two or three hours it is necessary to lie under a sheet wrung out of cold water. One day, after a violent *kamseen* (wind of the desert), there was nothing to eat because the dinner tables, served in the open air, remained covered with sand, necessitating the prompt removal of all the viands. The wind was followed by a torrential shower which certainly cooled the air; but then, by way of compensation, an hour

Digitized by Google

or two afterwards there ensued a regular invasion of toads, snakes, frogs of abnormal bulk, and other specimens of the like *fauna* which consumed the rest of the evening in hunting them back to their haunts. Life in midsummer at Kassala is not (as Albert Smith's surgeon has it) "a bed of *tol. ros. !*"

June 22nd.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Cholera Bulletins.

DURING the past fortnight cholera has been very satisfactorily diminishing in Alexandria, and the average daily number of new cases is now only six, and on two days fell to three. In Cairo the new cases per day have fallen from more than 50 to an average of 28, with a minimum of 20. It is fair to say that the disease is being well kept under in Cairo by the Englishmen employed in sanitary, police, and scavenging work. In one of the quarters a Coptic family was caught burying a corpse without a death certificate, but there is no evidence of burials in the houses and gardens as took place in Cairo in 1883. I regret to have to report a general lighting up of the epidemic in Lower Egypt and in the provinces of Upper Egypt immediately south of Cairo. Excluding Cairo and Alexandria there are now every day from 47 to 106 cases reported from a total of thirty-eight towns and villages. The distribution in the provinces is as follows:—Ghizeh, two districts; Benisouef, three; Gharbiyeh, twelve villages, Behera seven, Da Kahlieh three, Charkieh four, Menoufieh one, and Galioubiyeh, two. But it must be remembered that in addition to these the disease is probably lurking in many country villages where the ignorance or laziness of the local officials has not yet discovered it. Dr. Wilson has now been sent to control the infected districts of Charkieh province, and the three English sanitary inspectors are all very hard at work fighting the disease.

Disinfection Difficulties.

Given a hopelessly ignorant public, a virulent epidemic, and a Government not habitually accustomed to repressive acts at variance with the habits of the people, and we have all the elements necessary to hamper the work of sanitary officials. I have already mentioned an attack in Alexandria upon a cholera ambulance waggon, and a free fight at old Cairo between an Italian disinfector and a hostile mob. Fortunately the native court of justice sentenced six men to prison for periods varying from two to six months for this attack. Then came nine days ago the revolution of about 500 Syrian students in the crowded and very sacred University of El Azhar with its 12,000 graduates of all ages from early manhood to grey old age. A Syrian from this turbulent section was attacked by cholera and removed to hospital where he shortly died. The old myth was at once started that the doctors had poisoned him, and when a second case occurred the doctor was not allowed to remove him. The Sheikhs of the Mosque were all absent and refused to come when invited by the police to quell the riot. Both doctors and police seem to have behaved with the greatest moderation, and fortunately they were all Mussulmans; but when they found that the governor who very pluckily went alone to expostulate with the rioters was severely stoned it was obviously time to put an end to the disturbance. Coles Pasha arrived with twenty picked men with loaded rifles and vainly essayed to open the mosque door, exposed to a storm of paving-stones from the windows of the precincts. He got the door slightly ajar and then fired into the mosque over the heads of the crowd. This was answered by yells and stones, and reluctantly the order was given to fire at the crowd. This produced an immediate disperal and the Syrians flew to their bedrooms to hide. The police dragged them out, arrested about 500, and marched them at once to prison. The next day the bulk of them were released, sixty-five are now being exiled, and fifteen are going to be brought to justice. The Khedive has, moreover, decided to close the Syrian section of the University for one year. The greatest credit is due to both Coles Pasha and the governor for a successful ending of a very dangerous episode, and they have both been publicly thanked by the Egyptian Government. Since that day there has been no interference with sanitary officers in Cairo. But in order to make thoroughly understood the serious and regrettable side of this incident I must remind readers that the theological University of El Azhar is the most renowned in all the East—for the pious a Rome and Jerusalem combined. A hundred years ago no Christian was allowed even to pass before its door, and one of the most hated incidents of the hated French occupation of this country was that Bonaparte converted the mosque into a temporary stable. It is difficult to believe that we shall not hear of this incident again. A very widespread belief is, unfortunately, current both in Cairo and the provinces that low-class Europeans are going about with sweatmeats to poison the faithful, and that this instead of cholera is the real cause of the epidemic. One despairs of finding any method to counteract an unfounded belief of this kind. With the exception of the English workers nearly all sanitary officers are Mohammedans, and the greatest care is being taken to avoid offending any religious feelings.

The Nile Flood.

There is no sign as yet of any rising of the Nile at Akasheh, south of Wady Halfa, and there can be no improvement in the water-supply of Cairo and the Delta for another six weeks. The Sanitary Department still has a very anxious time before it, but the most hostile foreigners and the most ignorant natives all agree in comparing the results of this year as favourably as possible with the supine inaction of the Egyptian "Conseil de Santé" during the cholera of 1883.

The Abbassiyeh Lunatic Asylum.

Although cholera pervades the conversation and demoralises the work of several departments, it is satisfactory to note that in spite of all drawbacks the steady reform of the Abbassiyeh Asylum is continuing. It is really wonderful to witness the peaceful revolution which Dr. Warnock has brought about during the last fifteen months. More than 200 new windows have been opened in the wards, and no longer is there any animal smell, though the wards are more crowded than ever, chiefly because by caring for the sick in a well appointed infirmary the death-rate has been diminished by about half. New baths have been built, the garden has been furnished with verandahs, and new cells have been constructed for excited patients. Best of all, instead of all the men sitting idly upon their beds all day, some 200 out of a total 500 are working every day, mostly as masons and carpenters. I have the authority of the Public Works Department for stating that the work turned out is extraordinarily good, and all the improvements so far have only cost £2000. Work for another £2000 is planned for the present year, and then—what then? Will His Highness the Khedive still insist that Dr. Warnock's appointment must be for only two years?

Cairo, June 10th, 1896.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen were at the ordinary meeting of the Council on Thursday, the 11th inst., elected examiners for the ensuing collegiate year in the subjects indicated, viz:—

First Examination—Membership:

Elementary Biology.—Peyton Todd Bowman Beale, F.R.C.S. Eng., L.R.C.P. Lond., of King's College Hospital; George Alfred Buckmaster, M.R.C.S. Eng., M.D., B.Ch. M.A. Oxford, of St. George's Hospital; Thomas William Shore, M.R.C.S. Eng., M.D., B.Sc. Lond., L.R.C.P. Lond., of St. Bartholomew's Hospital; and Thomas George Stevens, F.R.C.S. Eng., M.D., B.S. Lond., M.R.C.P. Lond., of Guy's Hospital.

Elementary Physiology.—John Rose Bradford, M.R.C.S. Eng., M.D., D.Sc. Lond., F.R.S., of University College Hospital.

Second Examination—Membership:

Anatomy.—Richard Clement Lucas, F.R.C.S. Eng, M.B. and B.S. Lond., of Guy's Hospital; George Henry Makins, F.R.C.S. Eng., L.R.C.P. Lond., of St. Thomas's Hospital; William Johnson Walsham, F.R.C.S. Eng., M.B. and C.M. Aberd., of St. Bartholomew's Hospital; and Alfred Harry Young, F.R.C.S. Eng., M.B. and C.M. Edin., of Owens College, Manchester.

Physiology.—John Rose Bradford, M.R.C.S. Eng., M.D. & D.Sc. Lond., F.R.S., University College Hospital; D'Arcy Power, F.R.C.S. Eng., M.A., M.B. Oxford, St. Bartholomew's Hospital; and Walter George Spencer, F.R.C.S. Eng., M.B. & M.S. Lond., Westminster Hospital.

Final Examination—Membership:

Midwifery.—William Duncan, F.R.C.S. Eng., M.R.C.P. Lond., M.D. Brux., Middlesex Hospital; Montagu Handfield-Jones, M.R.C.S. Eng., M.D. Lond., M.R.C.P. Lond., St. Mary's Hospital; Arthur

Digitized by Google

Hamilton Nicholson Lewers, M.R.C.S. Eng., M.D. Lond., M.R.C.P. Lond., London Hospital; and Amand Jules McConnell Routh, M.R.C.S. Eng., M.D. & B.S. Lond., M.R.C.P. Lond., Charing-cross Hospital.

First Professional Examination—Fellowship:

Anatomy.—William Frederick Haslam, F.R.C.S. Eng., L.S.A. Lond., Mason College and General Hospital, Birmingham; Walter Hamilton Acland Jacobson, F.R.C.S. Eng., M.B., B.Ch., M.A., Oxford, Guy's Hospital; Charles Barrett Lockwood, F.R.C.S. Eng., St. Bartholomew's Hospital; and John Bland Sutton, F.R.C.S. Eng., L.R.C.P. Lond., Middlesex Hospital.

Physiology.—Benjamin Thompson Lowne, F.R.C.S. Eng., L.S.A. Lond., Middlesex Hospital; Edward Albert Schäfer, M.R.C.S. Eng., F.R.S., University College, London; Ernest Henry Starling, M.R.C.S. Eng., M.B., B.S. Lond., M.R.C.P. Lond., Guy's Hospital; and William Stirling, M.D., C.M., D.Sc., F.R.S. Edin., Owens College, Manchester.

Diploma in Public Health—Part I.:

Arthur Pearson Luff, M.R.C.S. Eng., M.D., B.Sc. Lond., M.R.C.P. Lond., D.P.H. and F.P. & S. Glasg., St. Mary's Hospital.

Part II.:

Edward Seaton, M.R.C.S. Eng., M.D. Lond., F.R.C.P. Lond., F.C.S., F.I.C., St. Thomas's Hospital.

The following gentlemen having passed the necessary examinations and having conformed to the by-laws and regulations were admitted Members of the College, viz.:—

Carvell, John Maclean, L.S.A. Lond., London Hospital.
Lefevre, John Matthew, M.D. McGill, McGill College, Montreal, and University College Hospital.

The following gentlemen, whose names are arranged in order of seniority as Members in accordance with the by-laws, were admitted Fellows of the College, viz.:—

Tomlinson, William Henry, L.S.A. Lond., Owens College and Royal Infirmary, Manchester; date of membership, Oct. 21st, 1886.
Macnab, Allan James, L.R.C.P. Lond. (Surgeon-Captain I.M.S.), King's College Hospital; Jan. 27th, 1887.
Wood, John Forrester, L.R.C.P. Lond., St. Bartholomew's Hospital; May 9th, 1889.
Waddelow, John Joseph, L.R.C.P. Lond., L.S.A. Lond., King's College Hospital; July 30th, 1891.
Paling, Albert, M.B., B.S. Lond., L.R.C.P. Lond., Middlesex Hospital; May 12th, 1892.
Rayner, David Charles, L.R.C.P. Lond., University College and General Hospital, Bristol, and London Hospital; May 12th, 1892.
Smith, William Robert, M.B. Lond., L.R.C.P. Lond., L.S.A. Lond., King's College Hospital; Aug. 1st, 1892.
Coaker, Francis William John, L.R.C.P. Lond., London Hospital; Feb. 9th, 1893.
Baldwin, Aslett, L.R.C.P. Lond., Middlesex Hospital; July 27th, 1893.
Scrase, Frank Edward, L.R.C.P. Lond., University College and Royal Infirmary, Bristol, and St. Bartholomew's Hospital; July 27th, 1893.
Sharp, Arthur John, M.D. Lond., L.R.C.P. Lond., Guy's Hospital; July 27th, 1893.
Campbell, Robert, M.B. R.U. Irel., L.R.C.P. Lond., Queen's College and Royal Hospital, Belfast; Nov. 9th, 1893.
Maingay, Henry Bertram, L.R.C.P. Lond., St. Bartholomew's Hospital; Nov. 9th, 1893.
Taylor, Edwin Claude, M.D. Lond., L.R.C.P. Lond., Cambridge University and Guy's Hospital; Feb. 8th, 1894.
Adams, Evelyn George Beadon, L.R.C.P., Lond., St. Bartholomew's Hospital; May 10th, 1894.
Dick, John Lawson, M.B., C.M. Ed., L.R.C.P. Lond., Edinburgh University and St. Bartholomew's Hospital; May 10th, 1894.
Parry, Leonard Arthur, M.B. Lond., L.R.C.P. Lond., Guy's Hospital; May 10th, 1894.
White, Charles Powell, B.A. Cantab., L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital; May 10th, 1894.
Lockyer, Cuthbert Henry Jones, L.R.C.P. Lond., Charing-cross Hospital; July 30th, 1894.
Ray, John Howson, M.B., Ch.B. Vict., L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester; July 30th, 1894.
Stone, William Gream, M.B., B.Ch. Oxford, L.R.C.P. Lond., St. Thomas's Hospital; Nov. 8th, 1894.
Bryant, Charles Hilary, M.B. B.S. Durh., L.R.C.P. Lond., Durham University and Guy's Hospital; Feb. 7th, 1895.
Moffat, Henry Alford, L.R.C.P. Lond., Guy's Hospital; May 9th, 1895.
O'Hea, James Patrick, M.B. Lond., L.R.C.P. Lond., St. George's and St. Bartholomew's Hospital; July 29th, 1895.
Cavenagh-Mainwaring, Wentworth Roland, M.B. Adel., L.R.C.P. Lond., Adelaide University and London Hospital; Feb. 13th, 1896.
Woods, William James, M.B., R.U. Irel., L.R.C.P. Lond., Queen's College and Royal Hospital, Belfast, and London Hospital; May 14th, 1896.
Hamilton, George Gibson, M.B. Edin., Edinburgh Royal Infirmary and University, and Royal Infirmary, Liverpool; not previously a member.
Mahon, Ralph Bodkin, M.D., R.U. Irel., Queen's College, Galway, and Royal University of Ireland, Dublin; not previously a member.

One other candidate passed the examination, but not having attained the legal age of twenty-five years will receive his diploma at a future meeting of the Council. Fourteen candidates were referred back to their professional studies.

The following gentlemen having passed the necessary examinations were admitted Licentiates in Dental Surgery:—

Ashby, Edgar, Guy's Hospital.
Barnard, Walter Burrows, L.R.C.P. Lond., Charing-cross Hospital and the Dental Hospital of London.
Bascombe, Ernest Dare, Guy's Hospital.
Beyer, Ernest Fritz Bertram, Owens College and Royal Infirmary, and Victoria Dental Hospital, Manchester.
Bidlake, Luther, Guy's Hospital.
Blomfield, Edgar Athelstan, Charing-cross Hospital and the Dental Hospital of London.
Briant, Wallace Watson, Guy's Hospital.
Byrne, Thomas Wafer, University College, Royal Infirmary and Dental Hospital, Liverpool.
Carter, Stuart, Mason College, Queen's and General Hospitals, and Dental Hospital, Birmingham.
Coltman, Ernest, Guy's Hospital.
Conder, Harold, Charing-cross Hospital and Dental Hospital of London.
Connor, George Washington, M.R.C.S. Eng., Middlesex Hospital and Dental Hospital of London.
Cowles, Hector Charles, Guy's Hospital.
Crapper, Harold Sugden, Guy's Hospital.
Crosby, Alfred Edward Binnington, Guy's Hospital.
Day, Kendrew James, Charing-cross Hospital and Dental Hospital of London.
De Mierra, Albert, Guy's Hospital.
Dunlop, Harry, Charing-cross Hospital and Dental Hospital of London.
Dupigny, Joseph Elford, Guy's Hospital.
Edey, George Russell, Guy's Hospital.
Fisher, Sydney Bailey, Mason College, Queen's and General Hospitals, and Dental Hospital, Birmingham.
Harris, Harold Octavius Whitfield, Guy's Hospital.
Heeson, Edwin Ernest Darley, Guy's Hospital.
Hemsted, Frederick, Charing-cross Hospital and Dental Hospital of London.
Hill, William Edmund, Middlesex and National Dental Hospitals.
Hinchliff, Charles John, Guy's Hospital.
Howe, Albert Frederick Alonzo, Guy's Hospital.
Knaggs, Sydney Angelo, Charing-cross Hospital and Dental Hospital of London.
Lacey, William John Mark, Guy's Hospital.
Mardon, Frederick William, Charing-cross Hospital and Dental Hospital of London.
Moore, Hubert William, Glasgow University, Middlesex and National Dental Hospitals.
Mordaunt, Osbert, Charing-cross Hospital and Dental Hospital of London.
Mudie, Walter, Charing-cross Hospital and Dental Hospital of London.
Mullord, Charles, London and National Dental Hospitals.
Newbery, Ernest Arthur, Charing-cross Hospital and Dental Hospital of London.
Nixon, Arthur Percival, University College, Royal Infirmary, and Dental Hospital, Liverpool.
Oliver, Norman Henry, Guy's Hospital.
Orridge, Alfred Edward Horton, Charing-cross Hospital and Dental Hospital of London.
Padgett, Frank Joseph, Charing-cross Hospital and Dental Hospital of London.
Plumley, Arthur George Grant, Guy's Hospital.
Read, Arthur, Guy's Hospital.
Riches, Charles John Hurry, Middlesex and National Dental Hospitals.
Robey, Arthur Malcolm, Mason College, Queen's and General Hospitals, and Dental Hospital, Birmingham.
Sexton, Walter, Middlesex Hospital and Dental Hospital of London.
Skae, John Walker, University College, Royal Infirmary and Dental Hospital, Liverpool.
Snell, Norris, Guy's Hospital.
Staton, Harry Hamilton, Charing-cross Hospital and Dental Hospital of London.
Stevens, Richard Henry, Guy's Hospital.
Ta'Bois, Leopold, Guy's Hospital.
Tasker, Benjamin George, Guy's Hospital.
Tebbitt, Ernest Reginald, Guy's Hospital.

Sixteen candidates were referred back to their professional studies.

SOCIETY OF APOTHECARIES OF LONDON, JUNE, 1896.—The following candidates passed in the undermentioned subjects:—

Surgery.—C. H. Dearden, Leeds; G. C. Jackson, Cambridge and St. Mary's Hospital; P. R. Lowe, Cambridge and Guy's Hospital; W. McCall, Charing-cross Hospital; G. H. Ormsby, Westminster Hospital; D. F. Roberts, Guy's Hospital; M. Sharp, Royal Free Hospital; E. M. Vernon (Intermediate), Royal Free Hospital; and H. A. Walker, Manchester.

Medicine, Forensic Medicine, and Midwifery.—A. P. B. Ellis, Glasgow and St. Mary's Hospital; P. R. Lowe, Cambridge and Guy's Hospital; W. J. Lubeck, Madras and University College Hospital; B. R. Turner, King's College Hospital; E. M. Vernon (Intermediate), Royal Free Hospital; and W. J. Woodman, St. Mary's Hospital.

Medicine and Midwifery.—J. C. R. Curtis, University College Hospital; and M. K. S. Holst, Royal Free Hospital.

Medicine.—E. R. Bowen, Bristol; and H. Clapham, Sheffield.

Forensic Medicine and Midwifery.—T. S. Biggs, Guy's Hospital.

Forensic Medicine.—J. C. McWalter, Dublin.

Midwifery.—F. L. Angior, Liverpool; and C. H. Dearden, Leeds.

To Messrs. Angior, Bowen, Clapham, Dearden, Lowe, Lubeck, McCall, Ormsby, Roberts, Walker, Woodman, and Miss Holst the diploma of the society was granted entitling them to practise Medicine, Surgery, and Midwifery.

PRESENTATION TO A MEDICAL PRACTITIONER.—Dr. Samuel Lawrence of Montrose, the medical officer of the burgh, on his retiring, after a period covering fifty-four years of active professional service, has been presented by his friends in that town and district with a portrait of himself. It is painted in oils and described as a faithful, striking

portrait. At the bottom of the frame the following words are inscribed: "Samuel Lawrence, M.D. Presented by friends.—Montrose, June, 1896."

THE FREE HOME FOR THE DYING.—The concert on behalf of this national charity, given at Stafford House on June 9th, by permission of the Duchess of Sutherland, and under the patronage of the Princess of Wales and the Duke and Duchess of York, realised £237 5*s.* 6*d.*, in addition to which a lady sent a cheque for £500 to the honorary treasurer, Mr. William Hoare.

MEDICAL MAGISTRATE.—On the recommendation of the Earl of Cork and Orrery, K.T., lord lieutenant of the county of Somerset, the name of Mr. Edward England Phillips, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A. Lond. (retired), of Sydney House, Bath, J.P. for the county of Essex, has been inserted in the Commission of the Peace for the county of Somerset.

DIPHTHERIA IN LONDON.—The week ended June 13th witnessed a slight fall in the number of deaths registered from diphtheria in London, as compared with the week immediately preceding. The deaths in the three weeks ended June 6th had been respectively 56, 40, and 52; and the number in the week ended the 13th, while having a total 16 in excess of the corrected decennial average for the twenty-fourth week of the year, showed a fall to 49 deaths. Of these 5 were of persons belonging to Camberwell, and 3 of persons belonging to Bethnal-green, whilst several other parishes had 2 deaths each. All but one of the deaths were in young persons aged under twenty years, and 35 were of children under five years of age. The admissions to hospital in the week were 109, as against 132 in the previous week, and the Saturday found 753 cases under treatment, against 710 on the corresponding Saturday of May. In Greater London the deaths in the week from diphtheria were only 3 in number. Last week there was a further fall in the registered deaths from the disease in London, 40 being the total, or 7 in excess of the corrected decennial average for the twenty-fifth week. But the localisation of the disease in a fatal form was more pronounced, Poplar and Camberwell being each credited with 6, and 5 deaths being of residents of Islington. The admissions to hospital were 91, but the total of patients under treatment on Saturday last showed an increase of 2 on the previous week. The same disposition as to ages was witnessed, and the registered deaths from the malady in Greater London rose to 10. In this way the saving of life from this disease in the county of London was almost counterbalanced by the increase of fatal diphtheria in the suburbs.

THE DIFFUSION OF SMALL-POX.—The cases of small-pox arising in the metropolis have in the past two or three weeks shown some evidence of spread of the disease in certain parts of London. In the fortnight ended May 30th the cases removed to the hospital ships down the river numbered 8, and in the next week the same total was reached, followed in the week ended June 13th by 9 admissions. The total for last week was 18, or double that of the previous week. Much of this increase seems to be due to a localised outbreak of the disease in the parish of St. Mary, Islington. In one street in a poor and crowded district close to Finsbury Park there were 5 cases removed on Sunday of last week and several additional cases later in the week from the same street. A case has also been reported at Highgate. The number of patients remaining under treatment on the ships has risen from 19 at the close of May to 41 last Saturday. Figures from Gloucester show a continued decline in the amount of small-pox occurring in that city, the returns for the week ended on Thursday, June 18th, giving 16 fresh cases as the total of fresh notifications. The admissions to hospital were 12, the discharges 15, and the deaths 6 in number. Up to the date in question the aggregate of cases during the epidemic was 1952, and whilst it is locally looked upon as certain that the prevalence will now soon die out, it will probably be only after 2000 cases have been chronicled. Some interesting figures as to vaccination have appeared in the local press. It would seem that there have been performed, as a result of the small-pox prevalence, no fewer than 8400 primary vaccinations and 26,317 re-vaccinations, giving unitedly a total of 34,717 operations. Much credit is undoubtedly due to the vaccination committee of the guardians and—this being especially the case—also to the staff under them, including in the first place Dr. Bond. The task achieved has been an admittedly difficult one, and its accomplishment is matter for congratulation to all concerned. We trust that the amount of work has been equalled by the excellence of the quality. Occasion for further congratulation lies in the fact that the return of the Registrar-General for Ireland for the week ended June 13th contained an intimation that the end of the week found no patient suffering from small-pox in the hospitals of the city of Dublin, the last patient having been discharged that week. This is the first time that the hospitals have been free from cases of the disease since the week ended May 26th, 1894.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, JUNE 18TH.

The Dog Muzzling Order.

SIR LEWIS M'IVER asked the President of the Board of Agriculture whether, having regard to the facts that the muzzling order had now been in operation in London for four months, that during that time all the stray and ownerless dogs had been destroyed, and that the muzzle caused great torment and discomfort to dogs in this hot weather, he could now recommend a relaxation of the order.—Mr. Walter Long replied that during the last four weeks twenty-two cases of rabies in dogs had been reported in London and the Home counties and 2982 stray dogs had been seized in London, only 899 of which were claimed. These circumstances seemed to him to clearly point to the necessity for the continuance in force of muzzling regulations, and he regretted therefore that he could not accede to the suggestion of his hon. friend

Prevention of Cruelty to Children.

Mr. M'Cartan asked the Secretary of State for the Home Department whether his attention had been called to the published summary of the annual report of the National Society for the Prevention of Cruelty to Children, wherein it was stated that, on the year's revenue, as compared with expenditure, there was a deficit of £8500; and whether he was aware that a large proportion of the deficit arose through the society bearing the expenses of prosecutions of cases transferred to them by the metropolitan police and county constabulary, which, under ordinary circumstances, would be paid for out of public funds; and, if so, whether he was prepared to take such steps as would relieve the society from such expenses now and in the future.—Sir Matthew White Ridley replied that he saw from the society's report that the ordinary income for the year was less by nearly £6000 than the income of the previous year; but he was informed by the director and the report also showed that the decrease was almost entirely due to the fact that a reserve fund was raised by the society during the year. He was not sure that he understood what was the meaning of the hon. member in the second paragraph of his question, but costs of prosecutions, so far as they were provided for by law, fell upon the same fund whether the prosecutions were instituted by the police or by any other persons. He might add that the society informed him that they did not desire any such relief as that suggested, and that few things had been so valuable to their work as the cordial union which exists throughout the country between them and the police.

Street Accidents.

Questions were addressed to the Home Secretary with regard to the frequency of accidents in the streets arising from the practice of driving covered vans from which the driver is unable to see the traffic on either side of him, and Sir Matthew White Ridley, in reply, said that the number of accidents caused by covered vans was unhappily on the increase. Except, however, in the case of cabs and omnibuses the powers of the police extended only to the manner in which vehicles were driven and not to regulating the position of the driver in the vehicle. Special warnings were issued from time to time and distributed widely, but more than that he was afraid the police could not do.

FRIDAY, JUNE 19TH.

The Case of Surgeon-Captain Fowler.

Sir Walter Foster and Dr. Farquharson at this sitting of the House, and when the House was in Committee of Supply on the Army Estimates, brought forward the case of Surgeon-Captain Fowler, who was gazetted out of the Army because of certain proceedings in the officers' quarters of a militia regiment in training at Sheerness. These two members claimed that Surgeon-Captain Fowler had been unfairly treated by the War Office and that a court-martial should be held upon the proceedings in question.—Mr. Brodrick, Under-Secretary of State for War, resisted the claim, and defended the action of his Department, and nothing came of the matter.

MONDAY, JUNE 22ND.

River Pollution.

Mr. Bartley asked the President of the Local Government Board whether his attention had been drawn to a resolution of the General Purposes Committee of the County Council of Middlesex of the 9th inst., on the subject of the state of the River Brent owing to its pollution by sewage, and what steps were to be taken to remove this danger to the health of the western suburbs of London, especially during this hot weather.—Mr. Chaplin replied that he had received a copy of the resolution. Some time ago he undertook to communicate again with the Thames Conservancy Board and the Middlesex County Council as to preventing the pollution of the Brent, and this he had done. He was informed that in several of the cases of pollution of the river by sewage to which attention was drawn in the report on the subject made last year by one of the inspectors of the Local Government Board, either the pollution had now been

Digitized by Google

diverted from the stream or steps had been taken to abate it, while in two instances samples taken periodically since October last had been analysed and were reported to give good effluents He understood that writs had been issued asking for injunctions against two of the district councils referred to in the inspector's report. One of these councils had applied to the Board for sanction to a loan for works of sewage disposal, and he was informed that proposals were to be made to the other by their surveyor as to the execution of some additional works with a view of preventing the pollution.

The Preserved Peas Question.

Mr. George Whiteley asked the President of the Local Government Board whether his attention had been called to a decision given by the Deputy Chairman of the County of London Sessions condemning preserved peas as injurious in the preparation of which sulphate of copper was used; whether he was aware that in France the Government after an exhaustive inquiry permitted the unrestricted sale of such peas as quite harmless, and the same was the case in the United States, Denmark, and other countries; whether, as the Justices of Glasgow and Bristol had held that such peas were harmless, he would consider what steps could be taken to prevent the retail grocer being subjected to such prosecutions; and whether, if satisfied that such peas were harmless, he would issue a recommendation to the local authorities to discontinue such prosecutions?—Mr. Chaplin said that his attention had been drawn to this decision, but he was not in possession of any reports which had been made in France or other countries and which had led to the unrestricted sale of peas coloured with sulphate of copper at the rate of three grains of copper salt to one pound of peas, on the ground that peas thus coloured were quite harmless; nor had he seen the decisions of the justices of Glasgow and Bristol to which his hon. friend referred. Indeed he was not in possession of any evidence which proved that peas coloured as described might be habitually consumed without injury to health, and under these circumstances he was unable to make the recommendation which his hon. friend suggested.

Factory Legislation.

Sir Charles Dilke asked the Secretary of State for the Home Department, with regard to the statement of Her Majesty's Chief Inspector of Factories that the power of the Secretary of State to issue orders applicable to particular classes of work in specified areas where outwork was carried on under insanitary conditions would enable the sweating districts to be dealt with, to what extent steps had been taken to deal with the sweating districts under the provisions of Section 5 of the Factory Act of 1895.—Sir Matthew White Ridley replied that immediately after the Act of last year came into force he made very full inquiries with a view to determining the districts in which the section should be put into operation. The qualifications, however, introduced into the section in the House of Commons were so stringent that he found no case existed in which he had power to make the order. The right hon. gentleman would remember that before such an order could be made it must be proved that the number and distribution of the population, and the conditions under which work was carried on, were such as to involve special risks of injury or dangers to the health, not only of the persons employed, but also of the whole district. He did not know of any case in which those conditions would be complied with except when a district was suffering from, or was threatened with, a special outbreak of infectious disease originating among the sweated workpeople. If that state of things should arise, or if in any other way the conditions which the Act imposed were fulfilled, he should be ready to make the necessary order.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BARBER, P. E., L.R.C.P. Lond., M.R.C.S., has been re-appointed a District Medical Officer, Wortley.

BISSHOPP, FRANCIS R. B. M.A., M.D. Camb., has been appointed Honorary Consulting Physician to the Tonbridge Union and Infirmary.

BLAKISTON, A. A., M.R.C.S., has been re-appointed Medical Officer of Health for the Borough of Glastonbury.

BRADSHAW, W. L., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Third Sanitary District of the Wycombe Union.

BROWN, WILLIAM, F.R.C.S. Edin., has been appointed Honorary Assistant Surgeon to the Cumberland Infirmary, Carlisle.

BURMAN, F. J., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer of Health for the Wath Urban Sanitary District.

BUTTERS, GEO., M.B., C.M. Edin., has been appointed Medical Officer by the Kempston Urban District Council.

CAREY, ARTHUR JAMES, L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the No. 4 Sanitary District of the Axbridge Union.

CARGYLL, L. VERNON, F.R.C.S., has been appointed Assistant Surgeon to the Royal Eye Hospital, Southwark.

CHRISTIE, MARGARET M. T., M.B. Lond., has been appointed Assistant Medical Officer for the Workhouse of the Greenwich Union, vice J. H. Griffiths, resigned.

COLLINS, W. J., M.D., F.R.C.S., B.Sc., Cert. Pub. Health, has been appointed Surgeon to the Royal Eye Hospital at Southwark.

COLWELL, J. R., has been appointed Public Analyst by the Clerkenwell Vestry and the St. Giles's District Board of Works.

CROWE, DANIEL, M.B., B.Ch. Dub., has been appointed Medical Officer for the Molvey Sanitary District of the Nuneaton Union.

CUNNINGHAM, A., M.B., C.M. Glasg., has been re-appointed Medical Officer of Health for Oldbury.

DAVIS, HENRY, M.R.C.S. Eng., has been appointed Anæsthetist to the Dental Hospital of London, Leicester-square.

EGLINTON, G. W., L.R.C.P. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer of Health for Street, Somerset.

FAWCETT, WM. H., M.D. Brux., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Wimborne and Cranbourne Union.

FLETCHER, F. J., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer for the Burton Coggles Sanitary District of the Grantham Out-Relief Union.

FRASER, P., M.D. Edin., B.Sc. (Pub. Health), has been appointed Medical Officer of Health for the Menai Bridge Urban Sanitary District, vice H. Rees, resigned.

GILBERT, J. K. MARTYN, B.A., M.B., B.C. Cantab., has been appointed Assistant Resident Medical Officer to Queen Charlotte's Lying-in Hospital.

HARDMAN, F. H., M.B., M.S. Edin., has been appointed Medical Officer of Health for the Kingston Rural Sanitary District, and also Medical Officer for the Teme Rural Sanitary District.

HOSEGOOD, S., M.R.C.S., has been re-appointed Medical Officer of Health for the Swinton and Pendlebury Urban Districts.

MACQUEEN, A., M.D., C.M. Edin., has been appointed Medical Officer of Health for the Drayton Rural Sanitary District.

MURRAY, GEORGE R., M.A., M.D. Camb., M.R.C.P. Lond., has been appointed Physician to the Royal Infirmary, Newcastle-upon-Tyne.

PARKINSON, J. PORTER, M.D., M.R.C.P. Lond., F.R.C.S. Eng., has been appointed Physician to Out-patients at the North-Eastern Hospital for Children, Hackney road.

PEARSON, H. CARDEN, M.B., C.M. Edin., has been appointed Junior House Surgeon to the Borough Hospital, Birkenhead.

PHILLIPS, SIDNEY, M.D. Lond., F.R.C.P., has been appointed Physician to In-patients, St. Mary's Hospital.

PHILIPSON, G. H., M.D. Cantab., F.R.C.P. Lond., has been appointed Consulting Physician to the Royal Infirmary, Newcastle-upon-Tyne.

RICHARDS, H. M., M.D. Lond., B.S., L.R.C.P., M.R.C.S., has been appointed Medical Officer of Health for the Borough of Chesterfield.

ROSCOE, HENRY, L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer for the Crumpsalls Workhouse and the New Bridge-street Workhouse of the Manchester Township.

ROWLANDS, WM. H., M.R.C.S., L.R.C.P., has been appointed Assistant House Surgeon to the General Hospital, Birmingham.

SEYLER, C. A., has been appointed Public Analyst for the County of Pembroke, vice Morgan, deceased.

SNOWDEN, G. H., M.R.C.S., has been re-appointed Medical Officer for Halford Sanitary District of the Shipton Union.

SOPER, R. W., M.R.C.S., has been appointed Medical Officer of Health for Dartmouth Borough and Port.

SPOWART, T., L.R.C.P., L.R.C.S. Edin., D.P.H., has been re-appointed Medical Officer of Health for the Second District of the Wortley Rural Sanitary District.

STURGE, MARY D., has been appointed Anæsthetist to the Birmingham and Midland Hospital for Women.

TATE, WALTER W. H., M.D. Lond., M.R.C.P., has been appointed Assistant Obstetric Physician to St. Thomas's Hospital.

THURSFIELD, W. N., M.D. Edin., M.R.C.S., D.P.H. Camb., has been re-appointed Medical Officer for Ludlow.

WAINMAN, BENJAMIN, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Workhouse of the Hunslet Union.

WIGHTMAN, J. P., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Rawdon Urban Sanitary District, vice C. Dawson, resigned.

WILLIAMS, W. T., M.R.C.S., has been appointed Medical Officer for the Casual Wards and Test House of the Manchester Township.

WESTERN GENERAL DISPENSARY, Marylebone-road, London.—House Surgeon, unmarried. Salary £80 a year, with board and residence.

Births, Marriages, and Deaths.

BIRTHS.

BATTLE.—On June 21st, at Mansfield-street, Cavendish-square, W., the wife of W. H. Battle, F.R.C.S., of a daughter.

DIXEY.—On June 20th, at Woodgate, Great Malvern, the wife of Harry E. Dixey, M.D., of a daughter.

MANN.—On June 19th, at Newgate-street, Chester, the wife of Alfred Mann, M.D., of a son.

MCCONNELL.—On June 16th, at Manor House, Ryburgh, Norfolk, the wife of Dr. Henry McConnell, of a daughter.

MONRO.—On May 23rd, at Rhanaghat, Bengal, the wife of Charles G. Monro, M.B., B.C., Rhanaghat Medical Mission, of a daughter.

POWELL.—On June 21st, at Brighton, the wife of Walter Powell, M.R.C.S., L.R.C.P. Lond., of a son.

SANDBERG.—On June 19th, at Liverpool Lodge, Brixton-hill, S.W., the wife of Arthur G. Sandberg, M.D., of a daughter.

STURROCK.—On June 15th, at Arima, Broughty Ferry, the wife of J. F. Sturrock, M.B., of a son.

MARRIAGES.

CROSS—OWTRAM.—On June 18th, at the Parish Church, Beckenham, Geoffrey Cross, M.R.C.S., son of the late James Cross, Esq., of Gringley, Notts, to Mary Constance, second daughter of C. H. Owtram, Esq., of Rylston, Croydon-road, Beckenham.

JONES—ATKINS.—On June 24th, at Christ Church, Banbury, by the Rev. Canon J. Herbert Jones, vicar of St. John's, Waterloo, Liverpool, father of the bridegroom, and the Rev. C. E. Graham Jones, vicar, Clement Royds Jones, M.B., of Calveley, Cheshire, to Ellen, youngest daughter of Edward Atkins, of Banbury.

KIRKPATRICK—KING.—On June 17th, at St. Mary's Church, Old Swinford, Stourbridge, William Kirkpatrick, M.D., eldest son of the Rev. G. Kirkpatrick, of St. Catherine's, Rathfarnham, to Agnes Helen, eldest daughter of Charles King, of Oakleigh, Stourbridge.

MEGGISON—AUSTIN.—On June 16th, at St. John's Church, Lewisham High-road, Thomas Cockburn Meggison, M.D., son of the late John Mill Meggison, of Berwick-on-Tweed, to Mabel, youngest daughter of the late Charles William Austin, of Lee, Kent.

MOLE—CLARKE.—On June 17th, at St. Mark's Church, New Ferry, by the Rev. Herbert E. Willson, Alfred Ernest Mole, M.B. Edin., of Adlington, eldest son of the Rev. R. Hopkins Mole, to Margaret Louisa, only daughter of the late John Clarke, Esq., of Buckley.

MOBERLEY—RYLEY.—On May 14th, at All Saints', Ladysmith, Natal, George Keble Moberly, L.R.C.S., L.R.C.P. Edin., elder son of the late Canon Moberly, of Cintra House, Winchester, to Florence Ryley, second daughter of — Ryle, Esq., M.L.A., of Moortown House, Ladysmith.

PORTER—HONEYMAN.—On June 23rd, at St. George's, Hanover-square, Bruce Porter, Army Medical Staff, son of Captain Porter, late R.A., to Essie, widow of the late J. H. Honeyman, M.D., of Auckland, New Zealand.

SMYTH—TEUSH-HECKER.—On June 16th, at St. James's, Norlands, Surgeon-Captain William Johnson Smyth, M.D., M.S., attached to the Grenadier Guards, to Amy Fanny White, younger daughter of the late H. C. Teush-Hecker, of Misterton, Leicestershire.

DEATHS.

CHOLMELEY.—On June 18th, at Clarendon-road, W., William Cholmeley, M.D., F.R.C.P., aged 73.

GAYLEARD.—On May 28th, at Kingston, Jamaica, Christopher Gayleard, M.R.C.S. Eng., grandson of the late Hon. James Gayleard, aged 59.

QUALTROUGH.—On June 12th, at 2, St. John's-road, Upper Holloway, W. J. Qualtrough, L.R.C.P., L.R.C.S., aged 51 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the current half-year is given in this week's issue, which completes the first volume of the year 1896. The practice of supplying loose copies of the Index has been discontinued, and it is now placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1896 will be ready shortly. Bound in cloth, gilt lettered, price 18*s*.

Cases for binding the half-year's numbers will also be ready in a few days. Cloth, gilt lettered, price 2*s*.

To be obtained on application to the Manager, accompanied by remittance.

"SAFETY PARAFFIN LAMPS."

MR. R. P. BEATTIE, of 16, Arcadia, Gt. Dover-street, Borough, S.E., sends us a description of a safety lamp of which he is the inventor. Its chief merit is simplicity of construction, while there is little doubt that it would burn ordinary illuminating oil quite safely. It answers to the description of a safe lamp as laid down by THE LANCET Commission. The wick is contained loosely in a wick chamber, except at the bottom where it passes tightly through a plug into the oil reservoir. Thus while the wick absorbs enough oil to feed the flame the wick chamber itself is always empty; leakage, therefore, through the wick tube of oil is prevented. The inventor states that he demonstrates the safety of this burner by throwing a burning lamp into a bed to convince his audience that no disaster can happen, and he adds that "many of the more nervous spectators make for the door and appear relieved when the experiment is over."

A very ingenious invention is the "Equipose Lamp" of Mr. A. H. Thompson, of 18, Garford-street, Poplar, E., which was referred to in our notice of safety lamps in THE LANCET of May 16th. We have since had an opportunity of inspecting the mechanism of this lamp. As its name indicates, the device upon which its safe working depends is a delicate universal joint, by means of which, no matter what position the body of the lamp may take, the reservoir and chimney are always vertical. When the lamp is upset it is immediately extinguished, since the ingress of air is at once stopped. Indeed, when required, the lamp may be conveniently extinguished in this way. It is obvious that this principle can be applied to various grades of lamps. Lamps of this safe construction are particularly well adapted for use in warehouses containing inflammable goods, when, colza oil being used, they give a brilliant light and for this purpose have, further, the advantage of being easily extinguished without unlocking the lantern.

M.D.—The medical man's first duty is undoubtedly towards his patient. As she would be so much better off if she took her parents into her confidence his advice to her to do so would be sound. But the moral point is one for her to decide, while it is his first business to attend to her physical condition.

"DOES ILLNESS HAVE ANY BENEFICIAL EFFECT ON ITS SUBJECT?"

To the Editors of THE LANCET.

SIRS,—I am afraid it is rather late in the day to answer Dr. Harry Campbell's request in THE LANCET of Sept. 28th, 1895. I well remember a case which somewhat applies. During an epidemic of enteric fever a man came to hospital with gonorrhœa; in three or four days he developed enteric fever, the gonorrhœa disappeared, and I well recollect some four weeks later, on the first day of normal temperature, my ward orderly (male nurse) saying, "His gonorrhœa has come back." The statement I was easily able to verify; there was no gonorrhœa during the active process of the enterica. I made an entry in the case book to that effect at the time. I regret that as the case occurred abroad some three years ago I have not access to the record of the case so that I could give accurate dates, &c., but the incident has not faded from my memory. I think such an occurrence is not very uncommon, though at present I can give no others.

I am, Sirs, yours truly,

Sheerness, June 17th, 1895. M. P. HOLT, Surgeon-Captain A.M.S.

M.D. Ed., &c.—Our correspondent had better apply to the School of Languages, 161, Fulham-road. Arabic is not a difficult language to learn to speak fairly fluently; to read or write it is a different thing

C. G. H.—The work done by the unqualified assistant, as described by our correspondent, falls within the proper scope which has been defined by the General Medical Council.

WRIGHT AND WRONG.

The *Jarrow Guardian* of June 19th publishes the following:—

"Mr. and Mrs. Wright and Family wish to thank the large circle of kind friends for their warmest sympathy, and are thankful to say their son George is progressing favourably under the skilful treatment of Dr. J——.

"June 18th, 1896. "9, Park-road, Jarrow."

We omit Dr. J——'s name, and recommend him to insist that the grateful patients shall do so also in their advertisement to their friends.

M.R.C.S.—The objections to such a scheme for payment are innumerable. Has our correspondent any idea of the difficulty the country rector experiences in collecting his tithe?

THE VACCINATION ACTS AND BOARDS OF GUARDIANS.

A CORRESPONDENT calls our attention to an anti-vivisection leaflet which professes to show how the Vaccination Acts may be legally repealed by boards of guardians. Under the heading of "Suggestions" it is stated that it is not obligatory on boards of guardians to prosecute defaulters under the Vaccination Acts, and our correspondent asks for reference to the law on this point. The 27th Clause of 30 and 31 Victoria, Chapter 84 (1867) states positively and clearly that the guardians shall make inquiry, and "if they find the provisions of the Act have been neglected shall cause proceedings to be taken against the persons in default." There is no mistaking this language, but, unfortunately, by the Vaccination Amendment Act 34 and 35 Victoria, Chapter 98, the above Clause (Section 27 of the 1867 Act) is repealed. It is clear, however, that according to the principal Act any parent or person having the custody of a child, &c., who shall neglect "shall *be guilty of an offence* and be liable to be proceeded against summarily, and, upon conviction, to pay a penalty not exceeding 20*s*." We take it, therefore, that any one can prosecute—the guardians may, of course, if they like, and certainly, if any "Registrar" (Clause 31 of the Act of 1867) "shall give information to a Justice of the Peace, the Justice may summon the Parent or Person." It seems a great pity that Section 27 of the 1867 Act should have been repealed, as it has evidently left the matter somewhat in a state of uncertainty.

A. T.—We do not recommend individual practitioners. The matter is one upon which the family medical man is fully competent to advise.

THE WRIGHT DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—This fund is now closed and the balance (after expenses) has been handed over to Mr. Wright, who is grateful to the subscribers. Will you kindly allow me to add the following to the previous lists:—

	£	*s.*	*d.*
Mr. T. Brayton, Hindley, (additional)	1	1	0
Mr. Bradbury, Wigan ...	1	1	0
Dr. J. Ellis Jones, Chorley	0	10	0
Mr. Hannah, Ashton-in-Makerfield	0	10	6
Dr. Prebble, Blackburn ...	0	5	0
Mr. R. Price, Crewe ...	0	5	0
Previous amount	52	16	6

The Committee desire me to express their thanks to the Editors for their kindness in inserting the appeal in THE LANCET free of cost.

I am, Sirs, yours truly,

Wigan, June 22nd, 1896. WM. BERRY.

Shenly.—A piece of pressed yeast, about one-third of an inch cube, should suffice. By taking a small portion of the washed yeast and adding a drop of diluted tincture of iodine, a blue colour will result if starch is present.

"A DOCTORLESS HOSPITAL."

THE following very amusing if rather unkind skit on the recent position of affairs at the Liverpool Ladies' Charity and Lying-in Hospital is extracted from the *Liverpool Review* of June 6th. We regret to be unable to find room for a larger quotation, but refer our readers to the original:—

A DOCTORLESS HOSPITAL.

PROSPECTUS.

The List opens to-morrow and will close on the 1st of April next. No promotion money. No underwriting. No humbug. No preference will be shewn except to midvives. Doctors (sixpenny included), rigidly excluded.

A strong feeling having existed from time immemorial among midwives and old women that doctors should be abolished on the ground that those who superintend the arrival of passengers on this planet are quite capable of superintending the exit as well, it is proposed to start a new parent company to acquire and work, free from medical and surgical control, a number of Lying-in Hospitals throughout the country.

* * * * * * *

GENERAL MANAGER: THE MATRON MIDWIFE.
CONSULTING ENGINEER: THE MATRON MIDWIFE.
SECRETARY, PRO TEM.: THE MATRON MIDWIFE.

In order to ensure absolute freedom to the patients and the matron-midwife from the inhumanity of the medical profession, and the continuous annoyance arising from new and improved methods of treatment, the directors and the matron midwife have decided to open a Marine Lying-in or Laying-out Hospital and Sanatorium, on the most insalubrious portion of the Manchester Ship Canal. Any temporary rise in the death-rate will be compensated for by the certain absence of the medical profession.

* * * * * * *

Any qualified man found prowling within five miles of the doctorless hospitals of the company will be arrested and dealt with as the Matron-Midwife Commanding-in-Chief shall direct. Medical students caught poaching in the grounds will be summarily executed on the spot.

Any newsagent, porter, messenger, street arab, or other person found introducing THE LANCET, or any other medical paper, periodical, or book containing up-to-date professional literature, into the company's doctorless hospitals, either on land or water, will be carried before the Matron-Midwife Commanding-in-Chief and incontinently birched or lashed at her discretion.

Any director presuming to differ from the matron-midwife upon any point will be permitted to resign upon getting a written order from the matron-midwife.

* * * * * * * *

Intending patients must give notice at least twelve months in advance to the matron-midwife, of their intention to avail themselves of the place. In order to prevent mistakes in delivery of parcels, husbands are advised to have their wives photographed prior to despatching them to the company's doctorless hospitals, as the hospital will not hold itself responsible for errors in packing and transit.

Patients who have been seen by qualified doctors during the five years immediately preceding admission into the company's doctorless hospitals must sign a renunciation in the presence of the matron-midwife.

Patients who presume to expedite matters with undue precipitancy without consulting the matron-midwife will be expelled.

* * * * * * *

Each matron-midwife appointed by the directors of this company shall assume the courtesy title of doctor, and as many other titles as appeareth good in her sight. Each director may assume the style and title of matron-midwife if so inclined, and strive to live up to it.

* * * * * * *

Dying is strictly prohibited in all the doctorless hospitals of this company, and any patient suspected of a tendency to bring the hospital into disrepute by so mean an act will be summarily ejected.

Although dying on the company's premises is rigorously discountenanced, the directors do not wish to be harsh, and on application to the Matron-Midwife Commanding-in-Chief, printed application for leave to die at home or in the gutter may be obtained by delicate or perverse patients.

It must be understood that the decision of the matron-midwife is final and irrevocable in all things, and that the directors only act as her mouthpiece.

Country Practitioner must consult a solicitor. The answer to his question depends upon the reading of the Medical Act (1886), and as we cannot refer him to any previous decision the matter is one for legal advice.

"THE REMUNERATION OF MEDICAL MEN."

WE have had many letters on this subject, as the outcome of "M.D.'s" communication to us last week, for which we have been unable to find room. One correspondent, who draws a fairly apt parallel between the positions of the medical man and the barrister, has clearly no idea of the pecuniary position of the metropolitan hospitals.

THE HISTORY OF VACCINATION.

To the Editors of THE LANCET.

SIRS,—As the epidemic of small-pox is still raging at Gloucester, evidently from the neglect of vaccination, I venture to add my testimony to the many proofs of prevention, or at least palliation, of this loathsome and fatal disease. To Dr. Jenner we shall always feel a debt of gratitude, not only in this country but all over the world; but the operation was practised long anterior to Jenner's time, for it appears that a Benjamin Jesty of Downshay, as inscribed on his tombstone, was said to have performed the operation in 1774, whereas Jenner's first vaccination experiment was in 1796. It appears also that the county of Dorset lays claim to having originated vaccination, a farmer named Nash having performed the operation on himself with success. But I have every reason to believe that vaccination was practised for a long period anterior to either Jenner's or Nash's time. In the Sanscrit language there is a book written by Hauvantori, which states that the Hindoos at a very remote period practised vaccination, and I have in my possession some interesting and valuable remarks written by Colonel Ellis, which I believe were published in THE LANCET some years ago, respecting a description of vaccination taken from an ancient medical work, which informs us that the "Sakteya Grantham" a work in which very precise rules for vaccination are laid down. Colonel Ellis, who was many years resident in India and was an accomplished Oriental scholar, informs us that Emanuel Timoni and Jacyes Pylanini, two Italian doctors, are said to have introduced the operation from Circassia into Europe in the sixteenth century, and a comparison of their travels and writings with those of the Dhauwantari would tend to show whether either had borrowed from the other, and which of them had first practised this important discovery but none questioned benefit. I do not wish to detract from, or lessen, the reputation of the illustrious Jenner, but simply to show that vaccination was popular from a remote period. I would also mention that in the years 1839–40, when serving on board H.M.S. *Crocodile* engaged in suppressing the slave trade, slavers used to arrive from the coast of Africa to ports in the island of Cuba laden with slaves suffering from small-pox in its most virulent form, many of the dead being thrown overboard to make room for the living sufferers. This was a great loss to slave owners and speculation in slaves, and I was told that a doctor was sent out to vaccinate them previously to embarkation, the consequence being that they arrived free from disease. So this affords a convincing proof of vaccination even from a commercial point of view.

Alas, poor Jenner, his memory deserves a better fate; his statue still remains in a conspicuous part of the nave in the beautiful cathedral of Gloucester, also a painted window given by the local medical practitioners, whilst the city where he originated this beneficent boon o vaccination has found enemies to it. Trusting that when the Royal Commission comes out it will urge on both Houses of Parliament *compulsory* vaccination,

I am, Sirs, yours truly,
HENRY PEACOCK, M.R.C.P.Lond., F.R.C.S.Eng.
Bath, June 19th, 1896. Retired Surgeon R.N.

THE LATE DR. CHARLES RUMNEY ILLINGWORTH.

The following subscriptions have been received in addition to those announced in THE LANCET of June 20th:—

SOUTHALL'S ORGANIC MATERIA MEDICA. A Handbook of some of the more important of the Animal and Vegetable Drugs used in Medicine, including the whole of those contained in the B.P. Edited by John Barclay, B.Sc. Lond., some time Lecturer on Materia Medica and Pharmacy in Mason College, Birmingham. Fifth and Enlarged Edition, 8vo, 6s.

London: J. & A. Churchill, 7, Great Marlborough-street.

Price 6d., post free.

DIFFICULTIES under the INFECTIOUS DISEASE (NOTIFICATION) ACT, 1889.

*** The series of articles on "Difficulties under the Infectious Disease (Notification) Act," which recently appeared in the columns of The Lancet, have been reprinted in pamphlet form, it being thought that many would care to possess, in a convenient shape, an elucidation of the principal points on which doubts and difficulties have arisen, and the various decisions and official interpretations which have been given with regard to them.

The Lancet Offices, 423, Strand, W.C., and 1 & 2, Bedford-street (adjoining).

Fourth Edition, price 2s. 6d.

ON NEURASTHENIA, or BRAIN and NERVE EXHAUSTION, and the NERVOUS SEQUELÆ of INFLUENZA.

By Thomas Stretch Dowse, M.D. Abd., F.R.C.P. Edin.

Baillière, Tindall, & Cox, King William-street, Strand.

ON BRONCHIAL ASTHMA; its Pathology and TREATMENT.

By J. B. Berkart, M.D., late Physician to the City of London Hospital for Diseases of the Chest. Second Edition, entirely Rewritten, with 7 Plates, 8vo, 10s. 6d.

London: J. & A. Churchill, 7, Great Marlborough-street.

BY FREDERICK TREVES, F.R.C.S., Surgeon to, and Lecturer on Surgery at, the London Hospital; Examiner in Surgery at the University of Cambridge.

THE SURGICAL TREATMENT of PERITYPHLITIS: Anatomy, Characteristics, and Treatment. Price 2s. 6d.

By the same Author.

PERITONITIS: its Causes, Symptoms, and Treatment. (The Lettsomian Lectures, 1894.) Price 2s. 6d.

Bale & Sons, Great Tichfield-street, W.

By the same Author.

INTESTINAL OBSTRUCTION: its Varieties, with their Pathology, Diagnosis, and Treatment. (Jacksonian Prize Essay.) With 60 Illustrations. Price 8s. 6d.

Cassell & Co., London.

THE LANCET.—PUBLISHED EVERY FRIDAY. Price 7d., by Post 7½d.

"The most modern methods of treatment."—The Lancet.

"All deformities are carefully described and illustrated."—Medical Journal.

Baillière, Tindall, & Cox, London, Paris, and Madrid.

Now ready, price 1s.

APPLICATION of TRUSSES to HERNIÆ.

Clinical Lecture delivered at King's College Hospital. By the late John Wood, F.R.S., F.R.C.S., Professor of Clinical Surgery at King's College, Senior Surgeon to King's College Hospital. Reprinted from "Medical Examiner," and Illustrated by Matthews Brothers. Surgical Instrument Makers, 10, New Oxford-street, W.C.

London: Henry Renshaw, 356, Strand.

PUBLISHED 1894.

Sixteenth Edition, much Enlarged, and revised up to date, price 12s. 6d.

SQUIRE'S COMPANION to the BRITISH PHARMACOPŒIA.

"No man who has the faintest aspiration to be in the van of pharmaceutical progress can afford to ignore the claims this exact and comprehensive epitome of pharmaceutical information has to a place at his elbow."—Chemist and Druggist.

"It is considerably ahead of the average text-books, and affords a valuable standard of reference to those who are anxious to keep pace with pharmaceutical advances, the allusions relating in many instances to current literature bearing the date of the present year."—The Lancet.

"The present edition has evidently been revised with the greatest care, of which evidences are to be found almost on every page. Altogether, the improvements are so great that many of those who already possess the work will find it worth while to have the new issue."—Practitioner.

London: J. & A. Churchill, 7, Great Marlborough-street.

TO the MEDICAL PROFESSION.—The "CERES" LETTER FILES.

The Proprietors have removed this business to *16, Brook-street, W.*

The Lancet says:—'For simplicity in use and ready adaptability to varying needs and requirements of work, Mr. Vernon has devised a plan which will be difficult to rival."

Medical Men should call and inspect these time-saving appliances which are being so largely used by the profession.

Newly Revised Explanatory Pamphlet, 56 pp., 30 Illustrations, now Ready. Post free.

Note New Address — "CERES" DEPOT, 16, BROOK STREET, W. (Bond-street corner.)

MÖLLER'S COD-LIVER OIL.

THE LANCET, June 8th, 1895:

"It is now known that Cod-Liver Oil can be prepared not only free from objectionable taste, *but also from the tendency to cause unpleasant eructations.* ..... The first improvement was effected on the introduction of **PETER MÖLLER'S PROCESS,** which, when properly carried out, produces an oil free from repulsive taste, *but still not from the tendency to set up irritation in the stomach, with eructation as a sequel.* ..... The latter very disagreeable property has been removed by **MÖLLER'S NEW PROCESS.**"

We shall be glad to forward specimens of the new oil to any member of the Medical Profession or to send a presentation copy of Dr. Peckel Möller's recently issued work, which contains a full account of everything bearing upon the subject.

PETER MÖLLER, 43, Snow Hill, E.C.

THE HISTOPATHOLOGY OF THE

DISEASES OF THE SKIN.

By Dr. P. G. UNNA,

Translated from the German with the assistance of the author.

By NORMAN WALKER, M.D., F.R.C.P. Ed.,

Assistant Physician in Dermatology to the Royal Infirmary, Edinburgh.

"An important and valuable work. ... Should be read carefully by every dermatologist who wishes to keep abreast of his subject, and every practitioner who is interested in diseases of the skin."—THE LANCET.

"In the literature of the speciality there is *nil simile aut secundum*."—THE PRACTITIONER.

"Unna's book is a work which stands conspicuously alone in the annals of dermatology. ..... To this volume constant reference must be made by every dermatologist. ..... It will be long before a work can appear which will equal, much less excel, that of the Hamburg dermatologist."—DUBLIN JOURNAL OF MEDICAL SCIENCE, June, 1896.

"Unna's work will be read not only by dermatologists and pathologists. ... It may be recommended to every surgeon. ... In future no one will be able to write on any skin subject without having previously consulted 'Unna.'"—CENT. F. CHIR., 1895.

"To the dermatologist it is simply essential."—ZEITS. F. DERMATOLOGIE.

Edinburgh: William F. Clay, 18, Teviot-place.

SYPHILIS.

By ALFRED COOPER, F.R.C.S., Senior Surgeon to St. Mark's Hospital for Fistula; late Surgeon to the London Lock Hospital.

Second Edition, Edited by EDWARD COTTERELL, F.R.C.S., Surgeon (Out-patients), London Lock Hospital.

Enlarged and Illustrated with 20 full-page plates, 12 of which are coloured. 8vo, 18s.

"A very satisfactory exposition of the present state of our knowledge with regard to syphilis. ..... All the illustrations are of a high order of excellence."—THE LANCET.

London: J. & A. Churchill, 7, Great Marlborough-street.

NOW READY, profusely Illustrated, price 10s. 6d.

A GUIDE TO THE SELECTION AND ADAPTATION OF

ORTHOPÆDIC APPARATUS.

With a Detailed Description of their Salient Points.

By F. GUSTAV ERNST,

Orthopædic Mechanician.

"The illustrations of this work are excellent. The descriptions of the instruments are also good."—THE LANCET.

"..... We cannot but admire the ingenuity and skill shown in the instruments illustrated. Gentlemen who make a speciality of correcting deformities of the limbs or trunk will find the book a useful one for reference on the subject of apparatus."—MEDICAL PRESS.

"..... It is manifest, from the cleverly-designed apparatus illustrated and explained in this book, that Mr. Ernst is a thorough master of his vocation; and surgeons who may require mechanical support for their patients might consult Mr. Ernst's 'Guide' with great profit."—THE HOSPITAL GAZETTE.

SMRAGUE & Co., 22, Martin's-lane, Cannon-street, E.C.

8vo, pp. xvi.-374, with 63 Engravings. Price 14s. net.

TUBERCULOUS DISEASE OF THE BONES AND JOINTS.

By W. WATSON CHEYNE, M.B., F.R.S.,

Professor of Surgery, King's College, London.

Crown 8vo, cloth, pp. xvi.-196. Price 3s. 6d.

THE TREATMENT OF WOUNDS, ABSCESSES, AND ULCERS.

By W. WATSON CHEYNE, M.B., F.R.S.,

Professor of Surgery, King's College, London.

Young J. Pentland,

Edinburgh: Teviot-place. London: 38, West Smithfield, E.C

Fifth Edition, with Coloured Plates, price 12s. 6d.

DISEASES OF THE EAR.

By GEORGE P. FIELD, M.R.C.S.,

Aural Surgeon to St. Mary's Hospital and Dean of the Medical School.

"Very practical and helpful."—THE LANCET.

"It contains a novel feature. A number of plates are given on thick cardboard, the spot where the membrana tympani ought to be seen is perforated, and a coloured representation of the drum is pasted on behind. If the membrana be looked at through a speculum a more correct idea than any heretofore given will be the result."—MEDICAL TIMES AND GAZETTE.

London: Baillière, Tindall, & Cox, King William-street, Strand.

The Edinburgh Medical Journal

for JULY, price 2s.

Teratogenesis: an Inquiry into the Causes of Monstrosities, by Dr. J. W. Ballantyne.—Short Notes of Two Cases of Opium Poisoning, by Dr. James Ritchie.—On the Use of Plaster Moulds as a Basis for Models in Gynæcology and Obstetrics, by Dr. Berry Hart.—Autoscopy of the Larynx and Trachea, or Direct Examination without the Aid of the Laryngeal Mirror, introduced by Dr. A. Kirstein of Berlin, by Dr. Logan Turner.—Puerperal Pulmonary Thrombosis, with illustrative case, by Dr. Lamond Laskie.—Notes of Seventeen Consecutive Cases of Diphtheria treated with Antitoxin, by Dr. J. DISEASES OF THE SKIN.

AN OUTLINE OF THE PRINCIPLES AND PRACTICE OF DERMATOLOGY.

By MALCOLM MORRIS,

Surgeon to the Skin Department, St. Mary's Hospital, London, &c. &c.

With 8 Chromo-Lithographs and 17 Woodcuts.

"Notwithstanding the number of excellent works on dermatology that have been recently published, Mr. Morris's book, from its compactness and the completeness with which it epitomises the latest suggestions in therapeutics of the skin, giving full references, will doubtless find a large field of usefulness."—BRITISH MEDICAL JOURNAL.

"We think the manual before us fully equal in reliability, and far superior in convenience of portability and reference, to any treatise that we knew of already existing in the English, or, indeed, in any other language."—DUBLIN JOURNAL OF MEDICAL SCIENCE.

"It is a reliable and impartial exposition of the subject, written from a strictly practical standpoint, and we commend it heartily to the profession. The volume is small and compact, but contains a great deal in a condensed form."—THE AMERICAN JOURNAL OF MEDICAL SCIENCES.

Cassell and Company, Limited, Ludgate-hill, London.

The only preparation of Iodine which is uninjurious to the digestion because of the slow, measured absorption of Iodine in the form of Iodalbumine.

AN EXCELLENT SUBSTITUTE for COD LIVER OIL and IODIDES.

THE LANCET of January 6th, 1894, publishes a full analysis of the Wine, and after explaining the difficulty of extracting all the Iodine, THE LANCET analysis proved that the Wine contains no free Iodine, and yielded **2·5 gr. of Iodine per 1000 c.c.** "In view of these results, we regard this wine as an introduction of distinct importance in therapeutics, since it appears to place the use and administration of a valuable medicament on a more satisfactory basis than heretofore. Iodine has been sparingly employed hitherto on account of its irritant and other disagreeable properties. The above preparation, therefore, which contains **no free Iodine,** but which yields it in full quantity on the slightest provocation, is calculated to lead to more extended application. It certainly deserves trial." And

The MEDICAL TIMES AND HOSPITAL GAZETTE of April 28th, 1894, states that "It therefore contains a **large proportion of Iodine** in a **very palatable** and easily assimilated condition, and seems to be an excellent form of administration when that drug is indicated."

The BRITISH MEDICAL JOURNAL of January 12th, 1895, describes the Gibert Dispensary for Children at Havre, and says:—"Scrofulous, tuberculous, and syphilitic patients are abundant here, as in other poor districts. More than 3000 new patients have to be treated in the course of the year, and the constitutional treatment carried out has resulted in much experience of the action of many drugs. Thus Dr. Gibert, after a long period of administering Iodine, found **no form agreeable to children**, and suggested to Mr. Nourry, a chemist of great reputation in Havre, the advisability of preparing Iodine with Malaga Wine, which is agreeable to children. Iodine is therefore administered in this pleasant and effective form, and **the children willingly come to get it.**"

The MEDICAL PRESS AND CIRCULAR of March 27th, 1895 says:—"M. Nourry hit upon the happy expedient of combining Iodine with Tanin in Malaga Wine, the result being a **complete disguising of its objectionable taste,** rendering it more palatable to both children and invalids generally; and we consider, after trials extending over several months that its value in this connexion is not so well known to the Profession in this country as its merits deserve."

CLINICAL SKETCHES of January, 1896, adds to a previous notice published June, 1895:—"We think that this Wine is an excellent method of giving Iodine in a pleasant form, and a medicine which is pleasant is generally more beneficial than one which is nasty. The metallic taste of Iodine is not only liable to create revulsion but is very apt to interfere with the digestion of the patients, sometimes doing a great deal of harm in this way. In Iodinated Wine, the taste is not only agreeable, but the influence of the Iodine is satisfactory. We have used it in **rheumatoid arthritis** with marked benefit, and we would urge an extended trial of this remedy **in all cases where Iodine is indicated.**

NOURRY'S IODINATED WINE is not advertised to the public. It owes its success entirely to the Medical Profession.

Price 3/6 per Bottle—Containing twenty doses or enough for ten days' treatment. Special Terms for Physicians.

SAMPLE BOTTLES FREE TO MEDICAL MEN ON APPLICATION.

HOW IT DIFFERS.

PEPTENZYME

Is not like or similar to Pepsin and its compound products in use, and, in brief, this is the exact difference:—

1st.—**PEPTENZYME** contains the Enzyme Principles of Seven Digestive Organs or Glands, all of which are essential or Nature would not have supplied them. (*No other preparation contains the enzyme secretions of more than two glands—viz., Peptic and Pancreatic.*

2nd.—**PEPTENZYME** contains the Enzyme Secretions just as they exist in nature, isolated mechanically. (*In all other preparations the secretions are obtained by using chemical salts, mineral acids, or strong alkali, which injure their physiological functions.*)

3rd.—**PEPTENZYME** contains the Active Ferments of the Seven Organs or Glands as found in nature, and, what is of far more value and importance in restoring normal digestion, it contains the Mother Enzymes, which, when brought to maturity by growth and development, produce the active ferments in the organism by Nature's methods. (*No other digestive product contains the mother enzymes, as nothing but active ferments can be retained in preparations of a chemical instead of a physiological method of extraction.*)

4th.—**PEPTENZYME** digests food in an Alkaline, Acid, or Neutral menstruum. (*Pepsin and pepsin compounds have very slight action upon food except in an acid menstruum*).

5th.—**PEPTENZYME** digests all kinds of food. (*Other digestive compound products act only upon nitrogenous food, and perform that function imperfectly.*)

THE LANCET of August 17th, 1895, confirms the claims of PEPTENZYME.

PEPTENZYME has been introduced a year and a half. Since then nearly 5000 letters from physicians have been received commending it in the highest terms. The names and addresses will be given if desired.

PEPTENZYME is the most important, far-reaching advancement ever made in the production of Digestive Ferments for the treatment of Dyspepsia, Indigestion, Cholera Infantum, Vomiting of Pregnancy, &c.

PREPARED IN FORMS OF POWDER, TABLETS, & ELIXIR. SAMPLES AND PAMPHLETS, DESCRIBING PEPTENZYME AND WHAT THE SPLEEN DOES, FREE AND CARRIAGE PAID TO MEDICAL MEN.

EVERY PHYSICIAN

Has a certain class of patients who worry him a good deal, for while not being exactly ill or confined to their beds, they are always complaining of a feeling of depression, loss of energy, restlessness, insomnia and a general feeling of "je ne sais quoi;" and while these symptoms may indicate a certain form of neurosis or nervous debility, he is at a loss as to what to prescribe, for while there are numerous remedies for nervous diseases, he is often puzzled as to which to use. It is in this class of cases that CELERINA, a combination of Celery, Coca, Kola and Viburnum, is indicated, for while not acting as an unnatural stimulus, it soon restores the tired and jaded nervous system to its normal condition, and brings about a feeling of buoyancy and energy that will be pleasing and surprising to both physician and patient, and will induce him to confirm the verdict of his brethren all over the world as to the virtues of this preparation. It is put up in elegant and palatable form, and being made of the best material in large quantities, it is always uniform and certain in its results.

RIO CHEMICAL CO., St. Louis, Mo., U.S.A.

The above Preparation is prepared exclusively for the Prescriptions of Medical Men. A Sample will be sent free to any Medical Man who desires to test it, on application to

RIO CHEMICAL CO., 36, Basinghall St., London, E.C.

"Does not depress the Heart."

ANTIKAMNIA (C_NH_{2N-6}).

OPPOSED . . . . . TO PAIN.

PROF. HUGO ENGEL, A.M., M.D., *Fellow of the American Academy of Medicine, points out one or two important facts in regard to ANTIKAMNIA. He says:—*

"Antikamnia possesses no merit as a preventive of pain; its action is *nil* until the pain begins.

"Antikamnia, when given in five-grain doses every ten minutes until grs. xxx. have been taken, produces no effect whatever in a *healthy* person. As my investigation concerned its action under pathological conditions, I did not inquire further into the question how much more than thirty grains might be administered to a healthy person without any deleterious effect.

"The action of Antikamnia as an analgesic begins the moment an individual is attacked by pain; and here a great number of observations has established with me the following rule for its administration to adults:—

"As early as possible after the pain has developed—if possible, immediately after—Antikamnia grs. v. are taken; from three to four minutes later, if the first dose has no, or but little, effect, the same dose is repeated; and again three or four minutes later, provided again the effect is *nil* or not sufficient, this dose is administered the third time. Then I let the patient wait ten minutes; if by the end of that time the pain be greatly ameliorated but a trace of it still present, a fourth dose of gr. v. then (i.e., ten minutes after the third) given will generally stop the pain completely."

Prof. Engel's observations have been confirmed and reinforced in England by Mr. ACHESON WILKIN, L.R.C.P. & S., &c., and Mr. R. J. BLACKHAM, L.R.C.P. & S. &c. *See* MEDICAL REPRINTS, *Jan., 1896.*

EDINBURGH MEDICAL JOURNAL says:

"This is one of the many Coal-Tar products which have lately been introduced into medicine. . . . In doses of three to ten grains it appears to act as a speedy and effective antipyretic and analgesic.

The American antipyretic, anodyne, and analgesic, is a combination of Coal-Tar derivatives of the series CnH2n-6, into which the amines have entered, forming the various amido-compounds.

It has, in contradistinction to other coal-tar products, a stimulating action on the nerve centres and the vital functions, especially the cardiac system.

It occurs in microcrystalline powder, and is perfectly white in colour; of a slight pungently bitter taste and alkaline reaction. It is moderately soluble in water, more freely with glycerine sparingly added, and freely soluble in brandy, whisky, or wines, according to their alcoholic percentage. In liquid prescriptions, however, simple elixirs offer the best vehicles.

ANTIKAMNIA should not be dispensed, however, in any vehicle of acid reaction. It can be readily given in tablets, as well as in powder (dry on the tongue) followed by a swallow of water or wine.

DOSE for Adults—5 to 15 grains; for Children in proportion. As a pain reliever in Neuralgia, Rheumatism, &c., ANTIKAMNIA acts with safety, certainty, and celerity.

PRICE OF ANTIKAMNIA TO THE MEDICAL PROFESSION.—In three-grain or five-grain Tablets, or in Powder, 3s. 9d. per ounce. One-ounce packages only. Price to the public (on prescription only), 4s. 6d. per ounce.

Eminent Medical Men,

Officers of Health, and Trained Nurses, recommend Lifebuoy Soap for use during Epidemics. Read what Dr. Karl Enoch, Chemisch Hygienisches Institut, Hamburg, says in his report of Experiments made with Lifebuoy Soap:—

"The examination of the sample of LIFEBUOY ROYAL DISINFECTANT "SOAP furnished to me by the Hamburg Agents of Messrs. Lever Brothers, "Limited, of Port Sunlight, England, gives the following results as to its "action as a disinfectant.

"Solutions of one, two, and five per cent. of LIFEBUOY ROYAL DISIN-"FECTANT SOAP in water were made. These solutions were brought to bear "on a variety of clean cultivated germs or microbes (*Bacillus*), in each case a "certain exact time being allowed for the operation; and thus the capacity of "this soap for destroying the various live and growing germs was proved. To "carry out this the following species of germs or microbes, amongst others, "were used:—

"1. Typhoid Microbe. 2. Cholera Microbe, taken from Hamburg water. "3. Diphtheria Microbe. 4. Carbuncle or Boil Microbe.

The results were as follows:—

"1. The obstinate Typhoid Microbes, with the five per cent. solution, were dead "within two hours.

"The operation of this soap on the Cholera Microbes was very remarkable, and "showed this soap to be in the highest degree a disinfectant. These were taken "from Hamburg water, and showed a result as follows:—

"With the two per cent. mixture, Cholera Microbes were dead within fifteen "minutes.

"With the five per cent. same were dead within five minutes.

"3. The Diphtheria Microbes were killed after two hours, with the five per "cent. solution.

"4. The five per cent. solution was tried on fresh Carbuncle germs, and the "result showed that the Microbe life was entirely extinct after four hours."

GUARANTEED PERFECTLY PURE, and FREE FROM ANY INJURIOUS CHEMICALS.

LIFEBUOY ROYAL DISINFECTANT **SOAP.**

MEDICATED SOAPS,

Prepared under the direction of the Staff of the

LONDON SKIN HOSPITAL, FITZROY SQUARE, W.,

FOR USE IN THAT INSTITUTION.

	Price per Tablet.	s.	d.
Superfatted ICHTHYOL SOAP (containing 5 per cent. Ichth. Ammon.)		1	0
Superfatted BENZOIN SOAP (5 per cent. Tinct. Benz.)		0	8
Superfatted ICHTHYOL & TAR SOAP (5 per cent. Ichth. Ammon. and 2½ per cent. Ol. Cadini.)		1	0
HYGIENIC SOAP		0	8
Superfatted ICHTHYOL and PERUVIAN BALSAM SOAP (3 per cent. Ichth. Amm., 2 per cent. Bals. Peru, with Sapo moll. P.B.)		1	0
Superfatted CAMPHOR, SULPHUR, & PERUVIAN BALSAM SOAP (5 per cent. Camph., 5 per cent. Sulph. Precip., 3 per cent. Bals. Peru.)		1	0
Superfatted SALICYLIC SULPHUR SOAP (3 per cent. Salicylic Acid and 10 per cent. Sulph. precip.)		0	8

Messrs. Yardley & Co. assure the Medical Profession of the purity of the base of these soaps and of their careful manipulation.

With a knowledge of these facts, it is to be hoped that there will be no further necessity for obtaining supplies from the Continent.

TO BE HAD OF ALL CHEMISTS, OR OF THE MANUFACTURERS,

YARDLEY & CO., LIMITED,

RIDGEMOUNT STREET, LONDON, W.C.

An absolutely non-poisonous, non-corrosive, and most powerful

ANTISEPTIC, DEODORIZER, & DISINFECTANT,

(CHEM. FORMULA $C_6H_9.N.KSO_4$),

Possessing a germicidal action forty times stronger than Carbolic Acid and ten times stronger than Corrosive Sublimate.

CHINOSOL is, moreover, readily soluble in any proportion of cold water; the solutions do not coagulate albumen, and are therefore enabled to penetrate the tissues to an extent that no albumen-coagulating antiseptic can possibly do. As a deodorizer **CHINOSOL** is very efficient, possessing itself a characteristic, agreeable, and slightly aromatic odour. A further and most valuable feature of **CHINOSOL** is its **extreme portability.**

ONE OUNCE of CHINOSOL dissolved in 10 gallons of cold water provides a most efficient Deodorizer.
ONE OUNCE of CHINOSOL ,, 30 ,, ,, ,, a powerful Disinfectant.
ONE OUNCE of CHINOSOL ,, 60 ,, ,, ,, an efficient general Disinfectant.

GUY'S HOSPITAL GAZETTE, 9th May, 1896:—"The report which we have of its use at Guy's, where it has been used to a limited extent, is decidedly in its favour, and bears out what has already been stated as to its superiority over other antiseptics."

The JOURNAL OF STATE MEDICINE, May, 1896:—"Chinosol, from the experiments we have made, appears to be a most valuable disinfectant. Experiments on recent broth-cultures of *Staphylococcus Pyogenes Aureus* showed that a solution of 1:25,000 *was fatal in ten minutes.* These results should cause this substance to prove of *great value in antiseptic surgery.*"

CHINOSOL FLUID is **indispensable** in all cases where a prompt and effective germicide and deodoriser is required; it can be employed in the Sick Room as a spray, or for washing floors and walls of Hospitals, Public Institutions, Schools, Barracks, Ships' Decks, &c. Chinosol Fluid does not contain soapy or resinous matter, it consequently does not leave a slippery surface.

Literature, Bacteriological Report, and Samples of CHINOSOL in various forms sent free to the Medical Profession.

Chinosol is sold by all Wholesale and Retail Chemists, or where not obtainable, please apply direct to

B. KÜHN, 36, ST. MARY-AT-HILL, LONDON.

MEDICINAL PREPARATIONS.

NAME.	PROPERTIES.	DOSE.
ANTINOSINE	Iodoform substitute, being the sodium salt of Nosophen, a blue powder soluble in water.	As gargle and for irrigation in 0·1 to 0·25 per cent. solution, or undiluted in powder form like iodoform.
CARNIFERRINE	Iron salt of phospho-carnic acid, containing 30 per cent. iron in an active and easily assimilable form.	8 grains daily for adults, 3 to 5 grains for children, as a powder or in tablets or pills.
CREOLIN	A refined preparation of JEYES' FLUID for medicinal purposes, forming an emulsion with water, used as a powerful non-irritating antiseptic.	In ½ to 2 per cent. solution.
EUDOXINE	A reddish-brown tasteless powder, insoluble in water, combining the properties of Nosophen and Bismuth. Used as an internal antiseptic.	5 to 8 grains thrice daily; children ¾ to 3 grains thrice daily according to age; infants ⅛th to ¾ grains thrice daily. Best given in powder or pills.
JEYES' FLUID	A coal-tar disinfectant of uniform, constant, and active composition, used as a general disinfectant.	In 2 to 5 per cent. solutions, and in soaps, disinfectant powders, &c.
JEYES' SOLUBLE FLUID	A refined preparation of JEYES' FLUID, forming a clear solution with water; for sterilisation of surgical instruments and as a general antiseptic.	For sterilisation purposes, in 2 to 3 per cent. solution; for irrigations, in ½ to 1 per cent. solution.
LYSIDINE	A colourless liquid and uric acid solvent in gouty disorders.	30 to 150 minims in a pint of aërated water, given daily.
MIGRAININE	A powder easily soluble in water, combining the action of antipyrine and caffeine. Used in neuralgia, migraine, and sick headaches.	16½ grains, best given in water and taken on an empty stomach, after which two hours' rest should be enjoyed. A second dose should only be given in exceptional cases, and not before the lapse of two hours after taking the first dose.
NOSOPHEN	Tetra-iodo-phenolphtalein, a greenish-yellow powder, insoluble in water, tasteless, and odourless, containing 61·7 per cent. iodine. A powerful substitute for iodoform, free from poisonous and irritant properties.	Used undiluted, and also diluted in the form of powder, ointments, paste, gauze, &c. Internally in doses of 5 to 8 grains.
SYMPHOROL N	The sodium, lithium, and strontium salts of caffeine-sulphonic acid. A white powder soluble in water, used as a powerful diuretic.	15 grains four times a day, given in water.

Angier's Petroleum Emulsion.

WITH HYPOPHOSPHITES LIME AND SODA

IN

WASTING DISEASES OF CHILDREN.

ANGIER'S PETROLEUM EMULSION is peculiarly suited to the treatment of Children suffering from diseases of malnutrition and wasting and bowel disorders.

It is almost tasteless and children take it readily either alone or in milk or water, with which it mixes perfectly. It can be administered in the hottest weather without fear of disturbing digestion; while its antiseptic action in the intestines, together with its peculiar soothing effect, makes it of special value in the many forms of intestinal disorders so prevalent with children during the hot summer months.

In 6 & 12 ounce bottles; of any Chemist. Free Sample on application.

ANGIER CHEMICAL CO., 32, SNOW HILL, LONDON, E.C.

ICHTHYOL.

MANUFACTURED BY

THE ICHTHYOL COMPANY, CORDES, HERMANNI & CO., HAMBURG.

ICHTHYOL is employed with advantage in—

Diseases of Women.	Diseases of the Throat. Influenza.
Gonorrhœa. Erysipelas.	Skin Affections.
Deranged Conditions of the Digestive and Circulatory Organs.	Inflammatory and Rheumatic Affections of all Kinds.

ICHTHYOL—*Its extensive employment is indicated by the Reducing, Sedative, and Antiparasitic properties revealed by experimental and clinical observations, as well as by its Stimulating and Regulating effects upon the system.*

ICHTHYOL *is warmly recommended by Medical Men, both connected with Hospitals and in Private Practice, and is in regular use in University and Public Hospitals.*

PEPTONIZED MILK

(PATENT CONCENTRATED).

The remarkable value of Peptonized (*predigested*) Milk has now been completely established. Without calling for any digestive effort, it can, in the absence of all other food, supply the system for an indefinite period with the nutriment which it requires. The great drawback to the more extended use of Peptonized Milk has been the trouble, care, and even skill required to be daily expended to prepare a fairly palatable and uniformly peptonized product. These disadvantages are entirely obviated by the use of this Concentrated Preparation, as by mere dilution with water a **deliciously-sweetened Peptonized Milk, of uniform composition, can be instantly prepared by the most inexperienced person.**

In Tins, 2s. 6d.; in Half-Tins (Samples), 1s. 6d.

PEPTONIZED COCOA AND MILK

(PATENT CONCENTRATED).

In this preparation the Cocoa as well as the Milk is peptonized and rendered soluble, and **is therefore more readily assimilable than any other preparation of Cocoa extant,** and can be digested by even the most confirmed dyspeptic. Besides its **extreme digestibility,** its perfect palatableness renders it a **most delicious** as well as wholesome **beverage,** which can be taken alike by the invalid and by those who, although otherwise healthy and robust, frequently experience a difficulty in digesting any form of Cocoa. For **general convenience in use** it is unrivalled, as no addition of milk or sugar is needed, but only mixture with hot water.

Tins, 2s. 6d., to make fifteen breakfast cups of Cocoa, or ten or more breakfast cups of rich Chocolate. Also in Half-Tins (Samples), 1s. 6d. each.

N.B.—The milk used in these preparations is secured from farms under our control, and where the sanitary arrangements have been made perfect, and, in addition to this, sterilisation after the most approved modern methods is provided for, thus ensuring complete immunity from communication of the infectious diseases which are unhappily so often spread by means of milk.

OPINIONS OF THE MEDICAL PRESS.

THE LANCET, June 15th, 1889:—

"Peptonized Milk (Patent Concentrated) is an excellent article. In consistence it is like a thick cream, agreeable in flavour, and yet so well peptonized that it gives no coagulation with dilute hydrochloric acid, even after heating. It will be of great value. The Peptonized Cocoa and Milk (Patent Concentrated) is clearly founded on the above. In appearance it resembles chocolate cream, and it is delicate in flavour, and yet peptonized. It is almost needless to say of Messrs. Savory & Moore's novelties that they are well prepared."

The PRACTITIONER, July, 1889:—

"We have carefully examined and tested Savory & Moore's Peptonized Cocoa and Milk and Peptonized Milk, and have used them ourselves and for patients of fastidious appetite. We find them well peptonized, capable of keeping even when the tins are opened for a considerable time, and very palatable. The Cocoa and Milk forms a thin and inviting beverage of a pleasant nutty flavour, and is retained well even in cases of chronic neurotic vomiting. The Peptonized Milk mixes well with tea or coffee, and improves the taste of both. These properties render Messrs. Savory & Moore's latest preparations a valuable addition to the sick-room dietary, and we can recommend them to the profession."

The MEDICAL PRESS AND CIRCULAR, Sept. 4th, 1889:—

"The Peptonized Cocoa and Milk and Peptonized Milk introduced to our notice by Messrs. Savory & Moore, like everything emanating from their laboratory, are most carefully prepared and of the highest quality. There is, moreover, a delicacy in flavour and aroma with the Peptonized Cocoa which shows at once that the products of selected growths only obtain a place here. It is, therefore, one we can unhesitatingly recommend."

N.B.—THESE PREPARATIONS KEEP WELL AFTER THE TINS ARE OPENED.

SAVORY & MOORE,

Chemists to the Queen, H.R.H. the Prince of Wales, H.H. the Khedive of Egypt, &c.,

143, NEW BOND STREET, LONDON.

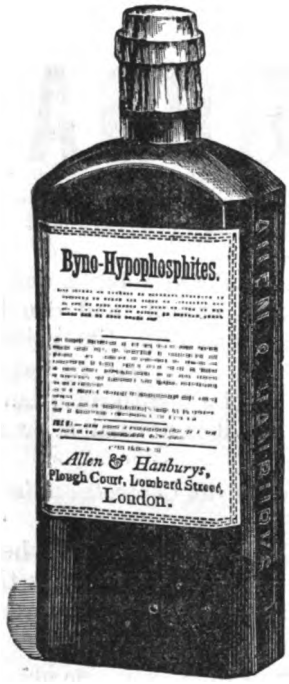
☞ "One of the most popular Tonics of the day."—*The British Medical Journal.*

Byno-Hypophosphites.

A great advance on the ordinary (Sugar) Syrups of the Hypophosphites.



Composition.

The **Vehicle** is **Bynin,** our Liquid Extract of Malt, so prepared that the entire activity of the digestive diastatic ferment is preserved.

The **active ingredients** consist of a **neutral** solution of the **Hypophosphites of Iron, Manganese, Calcium and Potassium,** together with the **Alkaloids of Nux Vomica** and **Cinchona.**

These latter are present in the form in which they occur in the natural state, combined with vegetable acids. Unlike many galenical preparations, however, the quantity of each alkaloid present is a fixed one—that of Strychnine being $\frac{1}{20}$ grain to each ounce of the mixture.

Therapeutic Advantages of Byno-Hypophosphites are briefly:

(a) The employment of sugar, usual in most preparations of Hypophosphites, is avoided, and a potent cause of dyspepsia eliminated by the substitution of **Malt Extract.** This is capable of digesting and aiding the digestion of a considerable amount of starchy food.

(b) The Alkaloids of **Nux Vomica,** especially Strychnine, are perhaps the most valuable gastric tonic in common use, while those of Cinchona possess properties essential in the treatment of functional nervous disorders and febrile conditions. Given in combination with their natural acids, experience has long shown that they are not only more easily tolerated, but more readily assimilated.

(c) The presence especially of Iron and Calcium in this preparation indicates its value as a direct hæmopoietic agent.

The **Hypophosphites,** taken as a group, are invaluable restoratives in cases of brain fatigue and nervous exhaustion. It is a matter of clinical observation that **Phosphorous,** essential in the production of the lecithin compounds of the nervous system, is **far more readily assimilated** in the form of **Hypophosphites** than as Phosphates, Phosphoric Acid, or even free Phosphorus.

In Phthisis, Hypophosphites are indicated for the following reasons:—
"They increase appetite and digestion, promote the formation of the blood, lessen cough and expectoration; they "appear to be more useful in the earlier stages of the disease, and are said to be more successful with young than "with old people. They are recommended in nervous and general debility, teething, spermatorrhœa, chlorosis, "and anæmia."—(RINGER.)

BYNO-HYPOPHOSPHITES is a clear amber coloured liquid of a slightly bitter but agreeable taste. It unites readily with water, and may be administered with safety to children.

DOSE.—For YOUNG CHILDREN, a tea-spoonful twice a day. For ADULTS, a table-spoonful three times a day. If given before meals it promotes appetite. If given after meals it accelerates digestion according to the physiological principles indicated above.

REPORTS FROM MEDICAL JOURNALS:—

The Lancet writes:—
"This is an excellent preparation, in which are ingeniously combined the hypophosphites of iron, lime, potash and manganese with the alkaloids of cinchona and nux vomica in combination with the well known active Malt essence—Bynin. We have proved its efficacy as regards digestive powers, while the tonic salts already indicated and the alkaloids of nux vomica were readily detected."

Medical Magazine writes:
"A distinct pharmacological success."

The Hospital Gazette writes:
"The value of such a preparation must be obvious."

The Chemist and Druggist writes:
"May be said to fill a blank in the well-occupied field devoted to hypophosphite remedies."

The British Medical Journal writes:
"One of the most popular tonics of the day."

Byno-Hypophosphites is put up in capsuled bottles at 2/6 and 4/6, and sold by Chemists everywhere. Price to the Medical Profession, 24/- and 41/- per dozen. SAMPLES SUPPLIED ON REQUEST.

Allen & Hanburys'

"Malted" (or No. 3) Food

FOR

Infants and Invalids.

THIS preparation is a perfectly assimilable farinaceous food. It is prepared on Baron von Liebig's principle of malting, but by greatly improved methods. It differs from other forms of Malted Food in that the malt is present in a soluble, concentrated, and most active form, rendering this Food not only most nutritious but self-digesting.

The basis of the Food is fine wheaten flour, rich in nitrogen, with this advantage, that a large proportion, but not all, of the starch is converted by the action of Malt Extract. The proportions are so arranged that the infant economy does not sink into an atonic condition, by having no work to do, as in the case of so many wholly digested foods, while care is taken that the child is not given too much starch to assimilate.

The Food is rich in soluble phosphates and albumenoids, constituents especially adapted for the formation of firm muscle and solid bone, and, with the addition of the proper proportion of milk and water, or milk only, it forms a perfect diet for young children.

ALLEN & HANBURYS have more recently introduced a "**First**" and "**Second**" **Food for Infants,** which differ in character from the "MALTED" (No. 3) FOOD, in that they are Milk Foods, and do not contain starch. These Foods are so arranged that, if the child be fed by hand from its birth, a series of foods is obtainable which is scientifically adapted to its progressive alimentary requirements.

The "**First Food**" (**No. 1**) is a correct substitute for mother's milk, and should be given for the first three months. It is prepared in the form of a dry powder, and is made from cow's milk, from which the excess of casein is removed, and the deficiency in fat, soluble albumen, and milk-sugar corrected.

The "**Second Food**" (**No. 2**) is the same as No. 1, but with the addition of Maltose, soluble Phosphates, and Albumenoids. There is no unconverted starch present. This should be given for the next three months, until the use of

The "**Malted Food**" (**No. 3**) may be naturally and advantageously commenced.

The experience of many years during which this preparation has been in use all over the world demonstrates how accurately chemico-physiological principles can be brought to bear in formulating a proper dietary.

The following quotation from the *British Medical Journal* will illustrate the practical value of this accurately-adjusted food :—

> "We have taken some trouble to have this Food carefully tested by skilled persons. The result of Dr. W——'s trials was decidedly satisfactory. Delicate children have, in many instances, improved under its use; infants who have thriven under its use fell off when it was discontinued, and it was generally liked by the children to whom it was given. In the same way, Dr. D—— was able to report very favourably of its influence upon the health, nutrition, and digestion of the children to whom it was administered in his hospital practice. In two large *crèches* the Food has been found very successful; in more than one instance the children who had been subject to sickness being freed from it by the use of Messrs. ALLEN & HANBURYS' Food."

The Lancet writes :—

> "An improved form of LIEBIG's well-known Food. It is excellent in quality and flavour."

Samples free to medical men on application.

First Food and Second Food in tins at 1/6 and 3/- Malted Food in tins at 1/-, 2/-, 5/-, & 10/- each.

"Lanoline" TRADE MARK.

Preparations.

"Lanoline" (*Liebreich*).

A preparation of the purified cholesterin fat of lamb's wool. Does not decompose or become rancid, and therefore never irritates the skin. It is the natural fat of the skin, and is therefore instantly absorbed by it. Supplied at 2s. 8d. per lb.

Toilet "Lanoline"

Is similar to the natural fat of the human skin and therefore forms an effective soothing and protective application for roughness, redness, chaps, abrasions, cuts, burns, eruptions and all forms of sensitive skin. Supplied to the medical profession in collapsable tubes at 5d. and 9d. each.

"Lanoline" Toilet Soap

Is super-fatted with "Lanoline," and therefore not only cleanses, but also nourishes, imparts suppleness, and protects the most sensitive skin. Perfectly suited for infants. Supplied to the medical profession at 5d. and 9d. per tablet.

Burroughs Wellcome & Co., Snow Hill Buildings, LONDON.

AWARDS.

GOLD MEDAL, International Health Exhibition, London, 1884.
FIRST ORDER OF MERIT AND MEDAL (Highest Award), Adelaide, 1887.
HIGHEST AWARD, Medical and Sanitary Exhibition, London, 1882.
FIRST ORDER OF MERIT AND MEDAL, Melbourne, 1888.

Liquor Pancreaticus (Benger).

For the preparation of peptonised or partially digested milk and other articles of food.

Simple directions for use enclosed. In 4 oz., 8 oz., and 16 oz. Bottles.

The *British Medical Journal* of April 1st, 1882, in an article on Benger's Preparations, says:—"Time and use have justified the claims put forward for these preparations."

The *London Medical Record* of March 15th, 1882, says:—"These are undoubtedly a great advance on any previous attempt in this direction. . . . The introduction of these preparations is a distinct advance in therapeutics."

The *Medical Times and Gazette* of September 8th, 1883, says:—"Benger's Preparations have deservedly a very high reputation, and are all largely used."

Liquor Pepticus (Benger).

An exceedingly active fluid pepsine, without disagreeable taste.

DOSE.—One or two teaspoonfuls with meals. In 4 oz., 8 oz., and 16 oz. Bottles.

Benger's Peptonised Beef Jelly.

A delicious quick restorative for Invalids and the Aged. In patent glass jars, no metallic contamination possible. Retail, 2s. each.

The Lancet says:—"It is a most valuable form of concentrated food."

The *London Medical Record* says:—"Invaluable for old people; also in convalescence from acute diseases."

A Physician writes:—"I feel I cannot express my gratitude to you sufficiently, as your Beef Jelly is the only thing my niece can retain, and it has certainly kept her alive for the last week."

Benger's Peptonised Chicken Jelly.

In similar glass jars. Retail, 2s. each.

The Lancet says:—"Mr. Benger's Preparations are now so well known that all we need say of the sample before us is—that it is excellent. It has a delicate chicken flavour."

The *Medical Press* says:—"Few modern improvements in pharmacy have done so much as Benger's Preparations to assist the physician in the treatment of the sick."

Benger's Preparations may be obtained through all Retail and Wholesale Houses and Shippers, or of the Manufacturers—

Maltine

A NUTRITIVE FOOD & AN UNEQUALLED STARCH-DIGESTANT.

"MALTINE" offers important advantages to those desirous of utilising the valuable properties of Malt in various lines of treatment. It is rightly characterised as—

I.—AN IMPORTANT NUTRIENT.

Because it has been found to contain the principles required to sustain strength and repair waste. Thus "Maltine" is—

(*a*) A food rich in carbohydrates—dextrine and maltose. These carbohydrates are the most assimilable of their class, and constitute, probably, a form of nourishment that is more easily digested than any other. "Maltine" is, then, a fat-making, force-giving food that is practically pre-digested.

(*b*) "Maltine" also contains a good proportion of the albuminoids and phosphates of the grains. Dr. MILNER FOTHERGILL specially valued this characteristic of "Maltine," pointing out that it was virtually the only means at our disposal for utilising vegetable albumen in a digestible or uncoagulated condition. Both the albuminoids and phosphates, derived from the grain by the process of malting, are in the most assimilable condition, and it is held that these natural phosphates are far more effective in the treatment of deficient bone-formation, than the salts in inorganic combinations.

Briefly, then, "Maltine" is a most easily digested Food, rich in the principles that make fat and build up flesh and bone.

II.—A VALUABLE DIGESTIVE AGENT.

(*a*) Because of its exceptional richness in **Diastase.** This delicate hydrolytic ferment is very susceptible to change and impairment, and only long experience and careful study will make it possible to obtain the fullest amount in the extract. The same process that has ensured the richness of "Maltine" in flesh-forming material is adapted to the preservation of diastase, and "Maltine" contains this useful ferment in unexampled proportions. By its action, "Maltine" has a pronounced effect on all farinaceous food, rapidly converting the starch into maltose and dextrine, and thus, when through debility, the system is unable of itself to properly perform this function, the use of "Maltine" will effect the digestion of food, and both directly and indirectly nourish the system.

(*b*) "Maltine" is not only of service in indigestion by reason of its action on the ingesta; it acts, further, as a digestive stimulant. Dextrin possesses undoubtedly the property of a gastric stimulant, causing an increased secretion of the gastric glands; and "Maltine," by virtue of its dextrin, stimulates and gives tone to these functions.

Among the other features which have won such general appreciation for "Maltine" may be mentioned its **CONVENIENT SEMI-LIQUID CONSISTENCE,** so much preferred by patients to the thick, viscid extracts; its **BRIGHT, CLEAR COLOUR and AGREEABLE FLAVOUR.**

The uses of "Maltine" are so well known that we need scarcely recapitulate them. Whenever it is desired to administer easily digested food containing the essential principles of nutrition, combat waste, improve the appetite, and counteract digestive weakness, "Maltine" is used with the happiest results. Its usefulness in Infant Feeding deserves, perhaps, more attention. By its action on cow's milk, the hard curd is broken up and rendered more easily digestible. Mixed up with warm milk, with or without a little cereal food, it constitutes a most successful aliment for infants.

"'Maltine' contains from three to five times as much diastase as any other extract of malt in the market."—Prof. ATTFIELD.

"Clinical experience enables us to recommend it as a nutritive and digestive agent, in virtue of its albuminoid contents and its richness in phosphates and diastase."—BRITISH MEDICAL JOURNAL.

BOVRIL

IS THE VITAL PRINCIPLE OF PRIME OX BEEF.
FROM CATTLE REARED IN AUSTRALIA AND SOUTH AMERICA.

ANIMAL FOOD offers a means of strength and stimulus not furnished by any other aliment, and the perfect assimilation of nutritious food is an essential condition of perfect health, but the high-pressure life of the present age demands an effective stimulative nourishment, taking little time to prepare or consume, yet not detrimental to the digestive organs, hence the introduction of Meat Extracts, Meat Essences, &c.

But BARON LIEBIG, the great German chemist, discovered and publicly declared on Nov. 11th, 1865, the unsuitableness of these preparations as resuscitating agents or as food in any direct sense. As he truly says :—

> "WERE IT POSSIBLE TO FURNISH THE MARKET AT A REASONABLE PRICE WITH A PREPARATION OF MEAT COMBINING IN ITSELF THE ALBUMINOUS, TOGETHER WITH THE EXTRACTIVE PRINCIPLES, SUCH A PREPARATION WOULD HAVE TO BE PREFERRED TO THE EXTRACTUM CARNIS, FOR IT WOULD CONTAIN *all* THE NUTRITIVE CONSTITUENTS OF MEAT." AGAIN—"I HAVE BEFORE STATED THAT IN PREPARING THE EXTRACT OF MEAT THE ALBUMINOUS PRINCIPLES REMAIN IN THE RESIDUE; THEY ARE LOST TO NUTRITION, AND THIS IS CERTAINLY A GREAT DISADVANTAGE."

The Albumen and Fibrine are the only nourishing portions of the Beef, and they are not present in Meat Extracts, &c., which, therefore, are only stimulants and no more nourish the system than the poker feeds the fire.

Bovril supplies the nourishment so conspicuously absent in these preparations, and this is secured by the introduction of albumen and fibrine (or rather the entire lean of beef) desiccated at a low temperature by special process, and subsequently pulverised to a minute degree of subdivision. By this means the entire nourishment of animal food is adapted to the feeblest and most sensitive system, and perfect assimilation is secured with the least possible expenditure of vital energy.

INVALID BOVRIL

Is specially prepared for use in the sick-room, and is put up in porcelain jars, obtainable from chemists and druggists only.

It contains the entire nutritive and stimulative constituents of Prime Ox Beef, and differs from ordinary Bovril in being more concentrated and quite devoid of seasoning, solving the great difficulty which all medical men recognise of furnishing substantial nourishment to the system through a debilitated stomach, nature being so effectively assisted that perfect digestion and assimilation is certain.

Strength to sustain the patient through the crisis of the illness, and strength to carry the invalid to a speedy convalescence and recovery is all important, and Bovril (which is not merely an Extract of Meat but Meat ITSELF) furnishes the system with renewed strength and increased vitality, being relished and retained when ordinary foods are rejected.

Some Important Products of Modern Pharmacy.

"TABLOIDS" OF ANIMAL REMEDIES.

DURING the present century no more important investigations have been undertaken than those which have established the therapeutic value of various animal substances in the treatment of more or less obscure diseases. Although the definite scientific side of the question still requires laborious research, many important results have already been obtained, and there is little doubt that when investigation has emerged from its at present embryonic stage, there will be opened up for this class of remedy a much wider field of usefulness than is dreamt of by those who are not cognisant of the immense strides that the movement is even now making. One of the most important facts yet established by laboratory trial and clinical test is the unreliability of liquid and solid extracts of the various animal organs now in use. Not only are these preparations liable to decompose shortly after they are made, but, owing to the fact that our knowledge of the ultimate chemistry of these organs is very limited, there has not yet been discovered a solvent or mixture of solvents which will effectually separate all the active principles. To ensure the presence of the *whole* of the substance and *all* the active principles of an animal organ it is necessary to exhibit it in the reliable, scientific, and accurately-dosed form of "tabloids." These are prepared from healthy organs, carefully selected and examined by a medical expert, and afterwards minced, dessicated, and compressed. As they are prepared in large batches a uniform percentage of active principles is secured throughout the whole. Modern medical literature is full of reports showing how active and reliable "tabloids" have proved in the hands of eminent clinicians.

In alphabetical order we subjoin a list of some of the animal substances we are now compressing into the scientific, reliable, convenient, and accurately-dosed form of "tabloids."

SACCHARIN "TABLOIDS."

The absolute harmlessness of saccharin has been conclusively proved by numerous and thorough scientific experiments and researches, and experience has corroborated the results arrived at. It has been shown that saccharin produces no injurious effects whatever upon the body; that it is discharged, unchanged and in its entirety, through the urine and fæces, and that it is absolutely inoperative as a retarding agent on bodily functions. When, therefore, sugar is prohibited as an article of food or as a condiment, saccharin satisfies the palate of the patient without aggravating the existing malady; on the contrary, its antiseptic influence may be for good.

The Editors of THE LANCET, replying to a correspondent in the issue of Jan. 18th, 1896, and referring to the researches of Dr. T. Stevenson and Dr. L. C. Wooldridge, make the following important statements with regard to the use of Saccharin:—

"(1) Saccharin is quite innocuous when taken in quantities largely exceeding what would be taken in any ordinary dietary.

"(2) Saccharin does not interfere with or impede the digestive processes when taken in any practicable quantity.

"(3) Our personal experience is that Saccharin may be taken for an extended period without interfering with the digestive and other bodily functions. Hence there is no reason to think that its continued use is in any way harmful."

Soluble Saccharin Powder is supplied to the Medical Profession in ¼-oz. and 1-oz. bottles with scoop, at 1/2 and 3/10 per bottle. Saccharin 'Tabloids,' containing ½ grain in each, are supplied in bottles of 100 and 200 at -/7 and 1/1 each.

"EMOL-KELEET."

Week by week we are receiving reports from the medical and nursing press and from practising physicians and surgeons regarding the value of "Emol-Keleet" in the treatment of a great variety of skin diseases, and for ordinary dusting purposes in the nursery and sick-room. As a nursery dusting powder, and for application before and after the appearance of bed-sores it is invaluable. For chafing and undue perspiration, and in the treatment of eczema, infantile eczema, intractable urticaria, and nearly every inflammatory or weeping skin disease, it is now largely prescribed.

We quote the following from a recent letter of a distinguished practitioner regarding a case of acute eczema:—"The eruption, though scattered over various parts of the body was most violent about the perineum, between the nates and the region of the pubes. There was the usual weeping discharge, especially in the last-named regions. The constitutional effect was very marked and the nervous symptoms were intense, so much so that the patient almost contemplated bodily destruction." After trying the usual standard remedies without effect, "Emol-Keleet" was applied. The result was excellent. "The intense itching abated, his life became bearable, his spirits rose, and he was able to take suitable nourishment. After a few slight relapses the patient rapidly regained his usual health."

Price to the medical profession at 9d. per tin.

BURROUGHS, WELLCOME & Co.

HOOPER'S ELASTIC WATER OR AIR BEDS AND CUSHIONS.

To be used on any ordinary Bedstead or Couch.

For Paralysis, Fevers, Consumption, Rheumatic Affections.

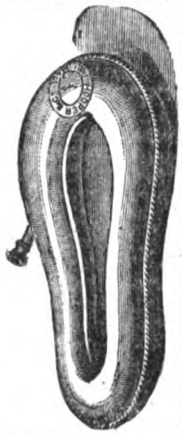
For Sale or on Hire.

For Bedsores, Spinal Affections, and all Bedridden Patients.

HIGHEST AWARD AT THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION, 1881.

☞ Messrs. Hooper & Compy. beg to invite the attention of the Profession to their system of hiring their Water Beds otherwise than in contagious or infectious diseases, and feel assured that where outlay is a consideration the Profession will appreciate and avail themselves of this hiring system.

ELASTIC INFLATING BED PAN.



ELASTIC INFLATING BED SLIPPER.

SANITARY BED PAN.

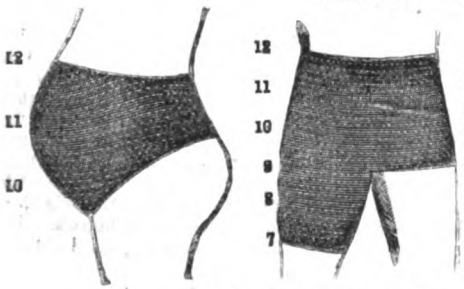
IN WHITE PORCELAIN OR GUTTA PERCHA.

Fitted with lid and stopper to prevent effluvia when removed from the Patient.

The Elastic Bed Slipper and Bed Pan, from their softness and elasticity, are peculiarly adapted to Ladies after confinement, and to Invalids who, from emaciation or other causes, cannot bear the hardness of ordinary utensils.

HOOPER'S SPIRAL ELASTIC BANDAGES.

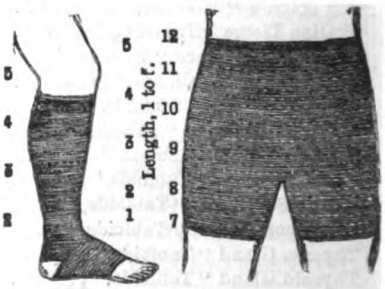
POROUS—ALLOWING FREE VENTILATION.



The measure should be taken next the skin, as follows:—

1, Round thickest part of instep.
2, Round ankle-bone.
3, Round small of leg.
4, Round thickest part of calf.
5, Round leg, just below knee.
6, Round knee-cap.
7, Round leg, just above knee.
8, Round middle of thigh.
9, Round top of thigh.
10, Round body at hips.
11, Round body at umbilicus.
12, Round waist.

The Length should also be given.



Experienced Male always in attendance for fitting Trusses, Belts, and Stockings.

HARTMANN'S

SAMPLES FREE ON APPLICATION.

HYGIENIC WOOD WOOL TOWELETTES.

Put up in the following sizes:—

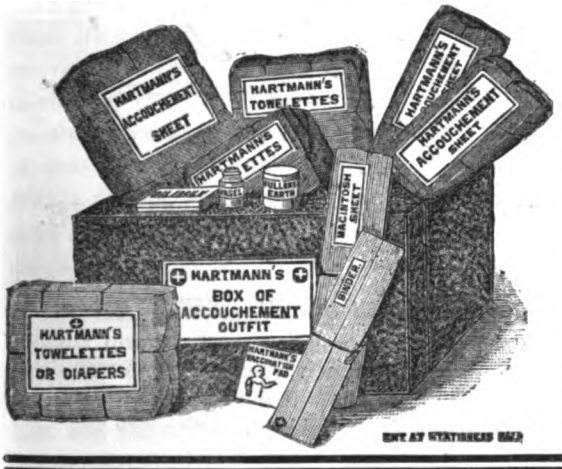
In YELLOW paper, 2/- per doz. size (special make for use after accouchement).
In GOLD paper, 2/- per doz. size.
In BLUE paper, 1/4 per doz. size (new make).
In WHITE paper, 1/- per doz. size.

} Superior to any other make.

FOR HOME USE, DELICATE HEALTH, FOR LADIES' TRAVELLING AND ACCOUCHEMENT THEY ARE INVALUABL AND INDISPENSABLE. THEY ARE SOFT, LIGHT, ANTISEPTIC, AND ARE SUPPLIED AT THE ACTUAL COST OF WASHING. AFTER USE THEY ARE SIMPLY BURNT.

Sample Packets of 1 dozen at 2s., 1s. 4d., and 1s. post free, or 12 Packets at 12s. 6d., 12s. 6d., and 9s. 6d.

Carriage Paid to the Medical Profession only.



HARTMANN'S

COMPLETE

GUINEA OUTFIT FOR ACCOUCHEMENT.

It contains all the necessary Hartmann's Absorbent Wood Wool Sheets, Sanitary Wood Wool Towelettes, Binders, Safety Pins, Carbolised Vaseline, Thread, Pads, Fuller's Earth, Oiled Silk, Mackintosh Sheeting, &c.

It affords great cleanliness and comfort to the patient, and diminishes the risk of puerperal fever.

Too much attention cannot be given in selecting the best articles for use during confinement; and in the interest of their patients we ask physicians to recommend Hartmann's Complete Guinea Accouchement Outfit.

A Smaller Outfit is also put up, price 10/6.

REDUCED PRICES to DOCTORS & NURSES.

The above Boxes will be sent to any Medical Man or Nurse on receipt of 19/- or 9/6.

HARTMANN'S

2d. each. WOOD WOOL 2d. each.

VACCINATION PAD.

Highly recommended by the Public Vaccinators.

Antiseptic and absorbent, soft and not liable to hurt the arm like shields.

It protects the arm from external violence.

It absorbs all discharges.

Most important of all, it reduces the risk of septic absorption and blood-poisoning.

It cannot be used a second time, like ordinary "shields," which it is too often the dangerous practice to use again and again.

Lastly, and not its least advantage, is its extreme cheapness.

Packed in boxes of 1 dozen, at 2/- post free to any Medical Man or Nurse.

Special Quotations to Public Vaccinators for quantity.

HARTMANN'S

SANITARY WOOD WOOL

SHEETS.

For Accouchement, Bedsores, Operations, &c.

PERFECTLY ANTISEPTIC, CLEAN, and COMFORTABLE.

The most comfortable Appliance for Accouchement ever made

"Risk of Puerperal Fever diminished."

A Great Boon for Patient, Nurse, and Physician in attendance.

Used in the Principal Lying-in Hospitals of London, Manchester, Edinburgh, Glasgow, &c.

These Sheets are made of Hartmann's Patent Wood Wool Wadding, the most absorbent substance ever known. They are most comfortable and healthy, are perfectly antiseptic, have not the disagreeable smell so common to indiarubber sheets, and are much cheaper. In Accouchement a large sheet is laid under the patient, it absorbs the discharge completely, and is SIMPLY BURNT after use. No soiled clothes; risk of puerperal fever greatly lessened; and perfect comfort and cleanliness.

Price of the Three Sizes - - 1/-, 1/6, and 2/6.

Sizes: 24 by 18 in., 26 by 20 in., 32 by 32 in.

"APENTA"

A NATURAL HUNGARIAN APERIENT WATER.

Bottled at the **UJ HUNYADI** Springs, Buda Pest, Hungary.

Under the absolute control of the Royal Hungarian Chemical Institute (Ministry of Agriculture), Buda Pest.

"This water is richer in mineral salts than all Continental bitter waters, and its efficacy is so great that even the smallest dose secures the best results."

John. Mobray

Sworn Chemist in Buda Pest.

APPROVED BY THE ACADÉMIE DE MÉDECINE, PARIS.

"THE LANCET" says:—

"A much-esteemed purgative water."—"Its composition is constant. The practitioner is thus enabled to prescribe definite quantities for definite results."—"A Natural Water."

"THE MEDICAL PRESS AND CIRCULAR" says:—

"Belongs to that large class of aperient waters which come from the neighbourhood of Buda Pest, commonly known under the generic name of Hunyadi."—"Contains a large amount of lithia. Specially marked out for the treatment of gouty patients."

"THE EDINBURGH MEDICAL JOURNAL" says:—

"One of the most valuable of aperient waters."—"Agreeable to take."—"Very efficient."—Reliable in its therapeutic effects."

"THE BRITISH MEDICAL JOURNAL" says:—

"Affords those guarantees of uniform strength and composition which have long been wanting in the best-known Hunyadi waters."—"Agreeable to the palate."—"Exceptionally efficacious."

"THE HOSPITAL" says:—

"Must be regarded as the finest amongst natural aperient waters known."—"Should be taken systematically every morning in quantities of about three ounces. A valuable water for those of gouty diathesis, and for those who are afflicted with chronic inflammation or constipation."

"THE BIRMINGHAM MEDICAL JOURNAL" says:—

"Peculiarly rich in mineral salts, containing indeed a larger proportion of sulphate of magnesia than any other mineral water at present in the market, and also a better proportion of that salt to its other chief constituent, sulphate of soda."

The highly favourable reports published by the "Gazette des Hôpitaux," "Presse Médicale," "Progrès Médical," "Médecine Moderne," "Journal de Médecine," Paris, &c., will be forwarded on application.

Full Analysis, Additional Testimony, and Samples will be supplied on application to

"Cyclists will find Malto-Carnis a veritable friend in need on long journeys." —*Health.*

"Dyspeptic persons who have been recommended to eschew tea should try Malto-Carnis." *The Med. Press.*

CAFFYN'S

Malto-Carnis

(Liquor Carnis, Malt, & Cocoa). Sizes: -/9, 1/9, & 4/6.

A NEW FOOD FOR CYCLISTS.

No greater test could be applied to any food than its capacity to sustain Bicyclists who are striving to break records; and we fearlessly challenge the whole world of food makers to find anything that will come near Caffyn's Malto-Carnis for this purpose. With a jar of Malto-Carnis strapped to his machine a man may travel from Land's End to John o'Groats, asking only for hot or cold milk by the way.

"A dessertspoonful mixed with a cup of hot or cold milk produces a breakfast-cup of an exquisite food-beverage containing sustenance sufficient for a light mid-day meal; hence for Cyclists and Professional Men in a hurry its advantages are most obvious. It satisfies the craving for stimulants by being a food and stimulant in non-alcoholic form."

BETTER THAN ALCOHOL.

"It is impossible to find a greater boon to the tired brain-worker and to the exhausted victim of high-pressure than is represented by MALTO-CARNIS, for such a blend represents the three great food-stuffs—the Proteids, Carbohydrates, and Fats—with a Stimulant which is much better than alcohol, because it does not excite and is not succeeded by depression."

☞ *Specimens supplied for test purposes by THE LIQUOR CARNIS CO., LONDON, E.C. Communications: ASTON CLINTON.*

NESTLÉ'S CONDENSED SWISS MILK

THE RICHEST IN CREAM.

PERCENTAGE OF BUTTER FAT.

Six Samples of NESTLÉ'S MILK bought at random at six different Shops, and analyzed by Mr. OTTO HEHNER, late President of the Society of Public Analysts, contained AN AVERAGE OF

13·13 PER CENT. OF BUTTER FAT.

Sample Tin sent free to the Medical Profession on application to HENRI NESTLÉ, 48, Cannon Street, London, E.C.

Cadbury's COCOA.

Absolutely Pure, therefore Best.

(NO ALKALIES USED.)

THE LANCET, referring to a thorough recent examination of Cadbury's Cocoa, says :—"The results leave no doubt of its purity and excellence, and show that there has been no treatment with fixed alkalies, or with ammonia. . . It represents therefore the standard of highest purity at present attainable in regard to cocoa."

ARMOUR'S

LACTATED PEPSIN.

Combines all the digestive ferments in approximately their natural proportions. It contains Pepsin, Ptyalin, Chymosin, Trypsin, Steapsin, Lactic Acid, Hydrochloric Acid, and Milk Sugar, and will be found to possess greater digestive strength than any similar preparation. It is well known that the medical profession has long used preparations composed of a mixture of pepsin and pancreatin, and continues to use them, notwithstanding all that has been said against such combinations.

In 1-oz., 4-oz., 8-oz., and 16-oz. Bottles.

A physician of high standing, who had given some attention to laboratory experiments with the digestive ferments, was asked why he prescribed "Armour's Lactated Pepsin"—a mixture of all the principal ferments. His answer was, that though theoretically opposed to its use, he obtained unmistakably good results, and such as he could not attribute to pepsin alone.

NUTRIENT WINE OF BEEF PEPTONE.

An elegant and acceptable form of pre-digested food, with the stimulants of both beef and wine. Peptone made from selected fresh beef, artificially digested by pancreatin, is the basis of Armour's Nutrient Wine. The familiar and largely used preparations known as Beef, Wine, and Iron are of undoubted value as a tonic, but possessing only the stimulating properties of beef in addition to the wine, are therefore devoid of the very essential constituent which Armour's Nutrient Wine possesses — namely, nutrition. Each pint bottle of Armour's Nutrient Wine contains, in a pre-digested form, all the nourishment and stimulant of one pound of lean beef; each fluid ounce, therefore, equals one ounce of uncooked beef free from fat. Epecially serviceable in all cases of Gastric Weakness, Debility, Languor, Failing Strength, and Exhaustion.

In 8-oz. and 16-oz. bottles.

"VIGORAL."

A Fluid Extract prepared from Armour's Solid Extract of Beef, combined with pure Beef in Powdered form, supplying nourishing and muscle forming constituents along with stimulating properties.

It is specially designed as a finely seasoned, nourishing, and stimulating beverage, soluble in hot or cold water.

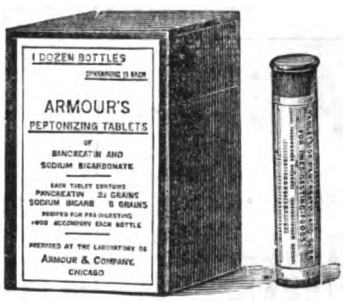
A REAL BEEF FOOD.

PEPTONISING TABLETS.

A convenient quantitative form of Pancreatin for pre-digesting milk and other foods for Infants and Invalids.

Each tablet contains: Pancreatin (U.S.P) 2½ grs., Sodium Bicarb. 8 grs. Put up in tubes of 15 tablets.

Formulæ for various processes of peptonising given with each tube.



ARMOUR & COMPANY, LONDON,

BARFF BORO-GLYCERIDE.

FOR MEDICAL AND SURGICAL PURPOSES.

BY ROYAL LETTERS PATENT.

From THE LANCET:—"Nothing can be better than the action of this compound."

From BRITISH MEDICAL JOURNAL:—"The simplicity of arrangement, the freedom from cumbersome apparatus, render it particularly well adapted for military surgery and for practice in rural districts."

"In Cystitis ..... this compound acts as a charm."—RICHARD BARWELL, Esq., F.R.C.S., Senior Surgeon of Charing-cross Hospital.

At the suggestion of several leading Surgeons, for convenience in carrying and for use at operations, BARFF BORO-GLYCERIDE is put up in Collapsible Tubes, each containing one ounce.

KREOCHYLE (BARFF & WIRE) LIQUID MEAT—Food and Stimulant for Invalids and Infants.

For full particulars and Samples apply to

THE KREOCHYLE CO., VIADUCT HOUSE, FARRINGDON STREET, LONDON, E.C.

Prices—5s. pound Bottles. 2s. 6d. half-pound Bottles. 1s. Bottles, and Tubes 6d.

BULLOCK'S PEPSINA PORCI.

DOSE—2 to 4 GRAINS.

ACID GLYCERINE OF PEPSINE

DOSE—1 to 2 DRMS. **(BULLOCK).**

In this preparation advantage has been taken of the solubility of Pepsine in Glycerine to produce a convenient and desirable *liquid form* of this valuable medicine; whilst the preservative qualities of the menstruum confer upon the Acid Glycerine of Pepsine the property of keeping for any length of time.

May be prescribed with most substances compatible with Acids.

In 4-oz., 8-oz., and 16-oz. Bottles, and in Bulk.

The published experiments of G. F. DOWDESWELL, Esq., M.A. Cantab., F.C.S., F.L.S., &c., Dr. PAVY, Professor TUSON, the late Professor GARROD, Dr. ARNOLD LEES, and others, conclusively demonstrate the excellence, high digestive power, and medicinal value of the above preparations.

J. L. BULLOCK & CO., 3, Hanover St., Hanover Sq., London, W.

LINCTUS TUSSI (Gale's).

A cheap and efficacious preparation, containing Opium and Ipecacuanha in combination with other expectorants.

LINCTUS TUSSI c. MORPHINA (Gale's).

An elegant preparation containing Morphia and Prussic Acid in combination with expectorants, &c.

LINCTUS TUSSI sine OPIO (Gale's).

A transparent, agreeable preparation, readily taken by children, containing dilute Nitric Acid, Ipecacuanha Wine, &c., in combination with demulcents and expectorants.

ELIXIR BORACIS CO. (Gale's).

An excellent application for Ulceration of the Mouth and Throat. One fluid ounce, diluted with half a pint of water, forms a pleasant antiseptic "wash" for cleansing the mouth and gums, &c.

LINIMENTUM ALBUM (Gale's).

Composition:—Linim. Ammoniæ, Linim. Saponis, Ol. Terebinth, &c. An elegant, white, creamy Emulsion.

UNG. CUTICULARIS (Gale's).

This Ointment possesses great advantages in certain Skin Diseases, Eczema, &c. It is pleasant to use, and does not stain the skin.

EMULSIONS of COD LIVER OIL and also of PETROLEUM. For full Particulars see our Current Price List.

ALL NEW CHEMICALS AND PREPARATIONS AS SOON AS INTRODUCED.

PRICE LIST and PILL CATALOGUE on application.

TAMAR INDIEN GRILLON.

A laxative, refreshing, and medicated Fruit Losenge, very agreeable to take, and never causing irritation. Its physiological action assures the immediate relief and effectual cure of

CONSTIPATION,

HÆMORRHOIDS, BILE,
CEREBRAL CONGESTION, HEADACHE,
LOSS OF APPETITE,
INTESTINAL OBSTRUCTIONS, &c.,

By augmenting the peristaltic movement of the intestine without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness; and the same dose always produces the same effect—that is to say, never needs increasing.

It is recommended by the most eminent physicians of Paris, notably Drs. BELIN and TARDIEU, who prescribe it constantly for the above complaints, and with most marked success.

Wholesale—London: E. GRILLON, 47, Southwark Street, London, S.E.

Sold by all Chemists and Druggists, 2s. 6d. a box, stamp included.

FERRATIN

Is *THE* Iron Preparation corresponding exactly with the Iron Compound which is ingested with Food, and which is found stored up in the tissues, especially in the Liver, as a reserve material for the formation of Blood.

THE LANCET writes:—"The constitution of Ferratin is sufficient reason for believing it to be of the greatest service in anæmia and other conditions of blood impoverisment in which iron is indicated, and we are hardly surprised to learn on this score also that excellent clinical results of its use have been recorded."

BRITISH MEDICAL JOURNAL writes:—"Far superior to Blaud's formula, which is considered the best of artificial combinations."

Samples and further particulars sent free to Members of the Medical Profession on application to

Messrs. DOMEIER & CO., 13, St. Mary-at-Hill, London, E.C.

Messrs. PARKE, DAVIS & CO., 21, North Audley Street, London, W.

GOLD MEDAL, INTERNATIONAL EXHIBITION, 1884. SILVER MEDAL, CALCUTTA EXHIBITION, 1883.

MIST. PEPSINÆ CO. c. BISMUTHO (HEWLETT'S).

COMPOSITION—Pepsine, Liq. Bismuthi, Sol. Opii Purif., Hydrocyanic Acid, P.B., Tinct. Nux Vomica, &c.

Highly recommended in various forms of dyspepsia, having a direct action upon the mucous membrane of the stomach and intestines as a sedative. It can be administered with marked and almost instantaneous effect in the irritative form of dyspepsia, more especially when *pyrosis* is a conspicuous symptom and pain occurs an hour or more after food. In simple neuralgic gastric pain following eating, occurring in feeble subjects, it is especially indicated, and even in *carcinoma* it has been used with great success in alleviating pain and vomiting.

In the dyspepsia of patients, dependent upon some organic disease, and where there is a decided loss of nerve power, it is of singular service. Thus, for instance, a person after a meal complains of a peculiar gnawing and emptiness with slight pain at the epigastrium—evident signs of general relaxation and loss of nerve power. Clinical experience has shown that it is of great service as a tonic and stomachic. A portion of its value arises, it may be, from its action upon the spinal motor nerve-centres. Be these things as they may, experience has abundantly demonstrated the value of the compound as a stomachic, antidyspeptic, and tonic. In general functional atony and relaxation, and in the various forms of dyspepsia, constipation, or diarrhœa, connected with atony of the visceral muscular coat, the MIST. PEPSINÆ CO. c. BISMUTHO is a very valuable remedy. In the *exhausting purging of Phthisis* accompanied with night sweats and restlessness Dr. Mathews, of Nantwich, has used it with marked and appreciable effect. **Price 10s. 6d. per lb.** **Dose—Half to one drachm, diluted.**

Physicians will please write "Mist. Pepsinæ Comp. (Hewlett's)."

VIN MARIANI

(ERYTHROXYLON COCA.)

More than 2000 physicians have certified to the immense sustaining, recuperative, and nourishing properties of this wine, which is indicated in cases of

OVER-EXERTION,
NEURASTHENIA,
NERVOUS DEPRESSION,
SLEEPLESSNESS,
NERVOUS DEBILITY,
CONVALESCENCE,
VOCAL FATIGUE.

When prescribing it the Medical Profession are strongly advised to specify "VIN MARIANI" in order to avoid the substitution of imitations often worthless, and consequently disappointing in effect.

Price 4s. per bottle; or 45s. per Dozen. To the Medical Profession any quantity post free, at rate of 42s. dozen, from WILCOX & CO., 83, Mortimer-street, London. Illustrated Treatise on Coca Free.

CIGARES DE JOY

ASTHMA
CHRONIC BRONCHITIS

One of these Cigarettes gives **IMMEDIATE RELIEF** in cases of **ASTHMA, CHRONIC BRONCHITIS, HAY FEVER, COUGH,** and **SHORTNESS OF BREATH,** and their daily use effects a **COMPLETE CURE.** The contraction of the air tubes, which causes tightness of chest and difficulty of breathing, is at once lessened by inhaling the medicated smoke of the Cigarette; a free expectoration ensues, and the breathing organs resume their natural action. Persons who suffer at night with **COUGHING, PHLEGM,** and **SHORT BREATH** find them invaluable, as they instantly check the spasm, promote sleep, and allow the patient to pass a good night.

These Cigarettes are perfectly harmless, and can be smoked by ladies, children, and the most delicate patients, as they are pleasant to use and contain no substance capable of deranging the system.

Price 2s. 6d., from WILCOX & CO., 83, Mortimer-street, London, and all Chemists. To the Medical Profession, 1s. 10d. post free.

CRYSTALLIZED DIGITALINE Nativelle.

The Paris Academy of Medicine awarded a prize of 8000 francs to M. Nativelle for the discovery of **CRYSTALLISED** Digitaline.

CRYSTALLISED DIGITALINE (NATIVELLE) is a definite substance that can always be relied on and administered with exactitude. After a few doses the pulsations of the heart become slower, more regular, and more energetic.

Prepared in Bottles of 60 granules, each granule containing a 240th grain (¼-milligramme). A Sample, with Opinions of the Press and Medical Profession, free by post from WILCOX & CO., 83, Mortimer-street, London. Sold by all Chemists.

WILCOX & Co.'s DESICCATED EXTRACT OF MALT

A Concentrated, Nutritive, and Digestive Food for **INVALIDS** and **CHILDREN.**

This preparation embodies all the beneficial properties of the most carefully prepared semi-fluid extracts, and possesses the additional advantages of greater richness in **DIASTASE** and the impossibility of fermentation. This powder may be eaten between bread-and-butter or dissolved in liquid, and, being a natural solvent of farinaceous material, it is strongly recommended as an adjunct to Children's Food and for ladies whilst nursing.

Prepared only by WILCOX & CO., 83, Mortimer-street, London, and put up in large bottles at 2s. 6d. each. Messrs. W. & Co. will be pleased to forward a sample of the above to any of the Medical Profession.

105, Victoria Street, Westminster, London, S.W.
Also from C. C. O. VAN LENNEP,
42, LONGRIDGE ROAD, EARL'S COURT, LONDON, S.W.

ANALYTICAL NOTICES.
"PURE TURKISH TOBACCO AND CIGARETTES.
"..... on inspection the leaf proved to be a choice variety of Dubec and according to microscopic examination is identical with that present in the cigarettes. The cigarettes yield a smoke possessing the well-known aroma peculiar to the Dubec leaf; but while it is particularly fragrant it is somewhat powerful also. The normal mineral constituent of genuine tobacco—namely, Nitrate of Potassium—was extracted from the leaf in good quantity."—THE LANCET, Jan. 13th, 1894.
"..... It was therefore a fine, well-preserved and highly aromatic specimen of pure manufactured tobacco, and specially adapted for cigarettes "London, Nov. 23rd, 1893.
"(Signed) GEO. BROWNEN, F.C.S."

UNDER ROYAL PATRONAGE.

The UNIVERSAL COOKERY EXHIBITION, held on May 1st, 1896, at the IMPERIAL INSTITUTE, awarded their MEDAL to

AYMARD'S PATENT MILK STERILIZER.

VERY SIMPLE. VERY CHEAP. VERY EFFECTIVE. REQUIRES NO WATCHING. IS READY IN A FEW MINUTES.

THE LANCET, May 23rd, 1896, says:—"This apparatus enables milk to be very quickly sterilised for the use of an infant in small quantities as required; and there is, of course, no separation of the cream, so that the result is better than when a number of small bottles of milk are treated at one time, according to the usual practice, for when these bottles become cold the cream rises and sticks around the narrow necks. An important advantage of sterilisation is that it prevents any risk from the pathogenic organisms so frequently conveyed by milk, such as those of tubercle, scarlet fever, and enteric fever."

The HOSPITAL says:—"Milk can thus be sterilised without that prolonged heating which is largely the cause of the peculiar taste of boiled milk, and also without the cream separating. ..... Is found in practice to be a very great benefit."

COMPLETE WITH SAUCEPAN, IN CARDBOARD BOX:—

Size.	Price.	Size.	Price.
½ Pint, suitable for one or two infants	£0 3 6	1 Gallon, best quality, for small schools	£1 7 6
1 Pint, best quality, for one or two infants	0 5 0	2 Gallon, best quality, for larger schools	1 17 6
1½ Pint, best quality, for small family	0 7 6	6 Gallon, with portable furnace and pan, suitable for [illegible]	[illegible]
3 Pint, best quality, for large family	0 10 6	large institutions	5 5 0

A specially made Thermometer if required, price 3/-. This Sterilizer is highly approved by all the leading Physicians, who are unanimous in their opinion that it is better for general use to dispense with a Thermometer and substitute a time allowance. These Sterilizers can be obtained from the following well-known Surgical Instrument Makers: Messrs. ARNOLD & SON, 31, West Smithfield, London; DOWN BROS., St. Thomas's-street, Borough, London, S.E.; FANNIN & CO., 41, Grafton-st., Dublin; WEISS & SON, 287, Oxford-st., London, and 42, King-st., Manchester.

Wholesale: AYMARD'S PATENT STERILIZER CO., **19a, COLEMAN STREET, LONDON, E.C.**

THE

THRESH "CURRENT STEAM" DISINFECTOR

Is adapted for HOSPITALS, WORKHOUSES, PUBLIC SCHOOLS, &c. Made in several sizes, with one or two doors. Portable Machines for Rural Districts. ***Prices 60 to 140 Guineas.***

"THE LANCET" SPECIAL SANITARY COMMISSION ON DISINFECTION.

Vide **THE LANCET**, Jan. 11th, 1896:—"To sum up, it will be seen that in no single particular have we found the invention of Dr. THRESH to come short of the requirements which we have laid down as essential in a machine intended for practical disinfection, ... and seeing how difficult a task it has hitherto been to satisfactorily comply in every particular with these conditions, the fact that such an appliance is now at the disposal of those responsible for the maintenance of public health will be welcomed by all interested in sanitary advance."

S. BARWISE, Esq., M.D., (State Medicine, London), Medical Officer of Health for the County of Derby, after testing the Machine, reported that: "After comparative trials with it and other steam disinfectors before the public, **both low and high pressure**, I find that penetration is quickest and the articles come out driest in the THRESH'S Machine. It is certainly the simplest and best machine I have yet seen." [illegible]

ENEMA and DOUCHE.

BALL NOZZLE SYRINGE.

THE LANCET, 21st March, 1896:—"Likely to prove of great advantage where thorough irrigation of a cavity is required."

The BRITISH MEDICAL JOURNAL, 29th Feb., 1896, says:—"It throws out a flattened sheet of fluid of almost spherical shape. Therefore the canal into which it is introduced will be uniformly irrigated."

The HOSPITAL, 11th April, 1896:—"..... An ordinary enema provided with a ball nozzle is clearly an ideal instrument for the washing out of canals and passages. The stream is gentle and equable, and an immense improvement on that of the older forms."

TO BE OBTAINED FROM ALL CHEMISTS.

The Trade supplied through Messrs. S. Maw, Son, & Thompson, and all Wholesale Houses.
BRITISH AMERICAN BALL NOZZLE CO. (Sole Manufacturers), 52, Oxford St., London, W.

UNIVERSAL TUBULAR WATER AND AIR BED

Prize Medals Sanitary Congress, 1878. Industrial Exhibition, York, 1879. Certificate of Honour, Sanitary Congress, 1879.

Brighton, 1881. International, 1881. Kensington, 1882.

POCOCK BROTHERS,

Patentees and Sole Manufacturers, 235, SOUTHWARK BRIDGE ROAD, LONDON.

Consists of a series of separate and distinct cylinders, any diameter and suitable length, made of Waterproof material either for Water or Air, fitting into a case which keeps them side by side, but slightly apart.

1. In cost it is less expensive.
2. It is warm and light, and well adapted for a camp or field-bed, being waterproof.
3. It is quickly filled and easily adjusted.
4. It admits of ventilation in the space between the tubes.
5. It can be regulated so as to relieve pressure from any part required.
6. By the addition of tubes it will raise one part of the body higher than the rest.
7. By the temporary removal of one or two tubes it affords room for the introduction of a bedpan.
8. It can be inclined to any angle (even when filled with water) to suit the condition of the patient.
9. It is free from noise and surging, so disagreeable to the invalid on changing his position on a water bed.
10. In case of injury to a tube it can be withdrawn, and a fresh one substituted at a trifling cost, and without loss of time; whereas the ordinary water-bed, if injured in any part (from being in one compartment), is rendered useless.
11. In the treatment of invalids, especially the insane, who are paralysed and have no control over their evacuations, they cannot lie in a pool of wet, the fluid passing away between the tubes.

ITS ADVANTAGES OVER ORDINARY WATER OR AIR BEDS ARE AS ABOVE.

IMPROVED POCKET CASE.

Suggested by T. H. WARD, M.D.

Extract from THE LANCET, April 11th, 1896.—Messrs. ARNOLD & SONS of West Smithfield have made a pocket-case for me which has some advantages over those generally used. The ordinary case is far too bulky to be constantly carried. Most miniature cases consist of at least three thicknesses of stiffened leather with side flaps and a clumsy fastening. They do not fold well and contain instruments so small as to be practically useless. The case shown in the drawing is made of flexible morocco leather. It is 4 inches long, 2 inches wide, and about a third of an inch thick. It contains: (1) scissors, one point sharp and the other blunt; (2) dissecting forceps, with spring catch, so as to act as artery forceps; (3) knife handle, with sharp-pointed scalpel and gum lancet; (4) probe, director, and exploring needle; (5) needles, ligatures, &c.; and (6) thermometer. The instruments are tools, not toys, being 4 inches long. The case can be carried in the watch pocket as constantly and with as little consciousness of its presence as an ordinary card-case.

Price Complete, £1 7s.

Manufactured by **ARNOLD & SONS,**

Barnwood House Hospital for

MENTAL DISEASES, Barnwood, near Gloucester. Exclusively for Private Patients of the Upper and Middle Classes. This Institution is devoted to the Care and Treatment of persons of both sexes at moderate rates of payment. The terms vary according to the requirements of the patients, who can have private rooms and special attendants, or be accommodated in Detached Villas and in the Branch Convalescent Establishment on the hills. Under special circumstances the rates of payment may be greatly reduced by the Committee.—For further information apply to J. G. Soutar, M.B., the Med. Supt.

St. Luke's Hospital, London, E.C.

Established 1751.

This Hospital was established for the Treatment of Mental Diseases of the Upper-middle and Middle Classes, for whom there is no statutory relief. Preference is given to acute cases, and these are admitted either gratuitously or on payment of a weekly sum varying from 14s. to 30s., according to the circumstances of each; and chronic cases can only be admitted at the higher rates. Patients are eligible for admission from any part of the United Kingdom.

Forms of application may be had from, and inquiries addressed to, the Secretary, at the Hospital.

PERCY DE BATHE, M.A., Secretary.

Warneford Asylum, Oxford.—This

Asylum, for the care and treatment of the Insane of both sexes of the Middle and Upper Classes, is pleasantly situated on Headlington-hill, near Oxford, and has been recently enlarged. The grounds are extensive, and cricket, tennis, billiards, dances, and other amusements are amply provided. There are now vacancies for patients at moderate charges. Voluntary patients can also be received.—For particulars apply to the Medical Superintendent, Dr. BYWATER WARD.

SPRINGFIELD HOUSE PRIVATE ASYLUM, BEDFORD.

For forms of admission, address, DAVID BOWER, M.D., as above.

(Dr. B. attends at 5, Duchess-street, Portland-place, W., on Tuesdays, from 3 to 4.)

Terms 2½ guineas per week.

There is a Vacancy for One LADY. Vacancies for Gentlemen will be announced when they arise.

INTEMPERANCE.

Buxton House, Earl's Colne, Essex.—

PRIVATE HOME for SIX LADIES. Nineteen years' experience. Very satisfactory results. Excellent Medical references. Inspection by applicants welcomed. Terms from 2 to 3½ guineas weekly. Medical Attendant, J. TAYLOR, Esq., M.R.C.S. Lond., L.S.A. Address, Mrs. or Miss PUDNEY.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

President: The Right Hon. the Earl MANVERS.

This Institution is for the reception of a limited number of Private Patients of Both Sexes, of the Upper and Middle Classes only, at moderate rates of payment. It is pleasantly situated on an eminence a short distance from Nottingham, and commands an extensive view of the surrounding country; and from its singularly healthy position affords every facility for the relief and cure of those mentally afflicted.

Particulars as to terms, &c., may be obtained from Dr. TATE, the Medical Superintendent.

Private Home for the Treatment of

INSANE LADIES,
ASHBROOK HALL, HOLLINGTON,

within half an hour's walk of St. Leonards-on-Sea, conducted by the Widow of the late Samuel Hitch, M.D., formerly of Sandywell-park, near Cheltenham, for many years Physician to the General Lunatic Asylum for the County of Gloucester.

Station: Warrior-square, St. Leonards. Telegraph Office: Hollington.

For particulars and terms apply to
Mrs. LETITIA A. HITCH or Miss ADAMS, Co-Licensee.

Church Stretton Asylum, Stretton

House, Church Stretton, Salop. Established 1853. (For Gentlemen only.) 600 ft. above sea level. Bracing air, farm, extensive grounds, and every facility for occupation and amusement; 4½ hours from London. Terms moderate. Suites of rooms for first-class cases.

Superintendent, CAMPBELL HYSLOP; Medical Superintendent, Dr. HORATIO BARNETT, B.A., M.B. Cantab., M.R.C.S., &c.

(See Medical Directory for further information.)

Grove House, All Stretton, Church

St. Andrew's Hospital for Mental

DISEASES,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President—The Right Honble. the EARL SPENCER, K.G.
Chairman of the Committee of Management—The Most Honble. the Marquis of NORTHAMPTON, K.G.

The Institution is pleasantly situated in a healthy locality, one mile from the London and North-Western or Midland lines, and one and a half hour only from London.

It is surrounded by more than 100 acres of pleasure grounds.

Great care is exercised in the classification of the Patients according to their habits and different degrees of mental aberration, so that those who are quiet or convalescent may not associate with those whose minds are more affected.

Ample means of occupation and amusement are provided, including Cricket, Croquet, Lawn Tennis, and Archery. There are also Billiard Rooms, and a large Recreation Hall and Theatre.

The terms vary from 25s. to £4 4s. week, according to the requirements of the case.

Patients paying higher rates can have Special Attendants, Horses, and Carriages; and Private Rooms in the hospital; or in detached villas in the grounds of the hospital; or at Moulton Park, a branch establishment, two miles from the hospital.

There is also a Seaside House, to which Patients may be sent.

For further information apply to the Medical Superintendent.

INEBRIETY.

TOWER HOUSE RETREAT & SANATORIUM (Ld.), Westgate-on-Sea, Kent.

Principal and Licensee—ALFRED F. STREET, M.A., M.D., B.C.Cantab.

Licensed under the Inebriates' Acts, 1879-88. The only establishment in the United Kingdom specially erected for the reception and treatment of Ladies and Gentlemen desirous of overcoming habits of Intemperance or of the abuse of Narcotic Drugs.

The house stands in its own grounds of nearly three acres, and is replete with every convenience, containing a large Billiard-room, spacious Drawing-rooms, Smoking-rooms, Bath-rooms, &c.

Patients can be received under the Act or privately.

For prospectus, forms (when required) for signature under the Act, and further particulars, address, Principal, Tower House Westgate-on-Sea.

THE YARROW HOME FOR CONVALESCENT CHILDREN, BROADSTAIRS.

This Home is now open and provision made for 50 Boys and 50 Girls.

It is not intended for the very poor, for whom charitable agencies already exist, but for the children of parents who from reduced circumstances or other causes are not able to give, entirely at their own cost, the advantages of a change of air at the Sea-side to their Convalescent children.

Boys between the ages of 4 and 14, and Girls, 4 and 16 years are admitted, irrespective of nationality and creed, provided their home training has been such as to make them fit companions for other respectable and well-mannered children.

A charge of 5/- per week is made for each child.

This Home is open throughout the year, and under the management of a highly experienced Matron. Medical Officer and Certificated Nurses form a part of the Staff.

Particulars and forms of Application may be obtained on application to the Secretary,

Mr. T. F. MYERS, at the London Office 73, Queen Victoria Street, E.C.

NURSE GOODERHAM,

MONTHLY NURSE

(*City of London Hospital Certificate*),

Address—20, THURLOE PLACE, SOUTH KENSINGTON, S.W.

St. Olave's Union.—Matron of the INFIRMARY.—The Guardians of the Poor of the St. Olave's Union are desirous of receiving applications for the appointment of MATRON of their Infirmary, Lower-road, Rotherhithe, S.E. The salary is £100 per annum, together with rations, furnished apartments, washing, and attendance.

The Infirmary contains 640 beds. An Assistant to the Matron is provided. Candidates must be single or widows, without children dependent upon them, not less than thirty nor more than forty-five years of age, have had training in a General Hospital or a recognised training school for Nurses, and acquired practical experience in the management of large institutions for the sick.

Candidates must submit unquestionable credentials of their ability and experience to undertake the supervision of the Nursing and the training of Probationers and Nurses in accordance with the Nursing scheme in force at the Infirmary, and carry out the orders of the Guardians and the Medical Officer in connexion therewith.

The officer appointed will be required to keep all the books and accounts and perform all the duties prescribed by the orders of the Local Government Board and the Guardians; to obey all lawful orders of the Guardians and the medical officer, and to aid the medical officer and steward in enforcing the due observance of all regulations for the government of the Infirmary by the inmates, officers, and servants.

The appointment will be made subject to the rules, regulations, orders, and approval of the Local Government Board.

Personally canvassing the Guardians is prohibited, and will be deemed a disqualification.

Applications, with copies of not more than five testimonials, to be made upon forms to be obtained on written application to me, inclosing a stamped and addressed envelope of foolscap size. The applications for the appointment must be received not later than Monday, the 6th July, 1896.

Selected candidates will have notice of the day and hour they will be required to attend a meeting of the Guardians.

By order,
E. PITTS FENTON, Clerk to the Guardians.

Clerk's Offices, 30, Tanner-street, Bermondsey, S.E.,

The appointment will be made on July 21st, 1896. Any candidate canvassing will be disqualified.

J. K. STONE, Secretary, Newport, Mon.

County Borough of Huddersfield.—

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.—The Council of the County Borough of Huddersfield are prepared to receive applications for the post of Medical Officer of Health for the Borough and Urban Sanitary District of Huddersfield.

The population of the County Borough is estimated to exceed 100,000, and the area is 12,088 acres.

The gentleman appointed will be required to devote the whole of his time to the duties of the office. Salary £400 per annum, with actual disbursements.

In addition to the ordinary qualifications in Medical Surgery and Midwifery, applicants for the office must be either registered as the holder of a Diploma in Sanitary Science, Public Health, or State Medicine under Section 21 of the Medical Act, 1886, or have been during three consecutive years preceding the year 1892 a Medical Officer of a district or combination of districts with a population according to the last published census of not less than 20,000, or have been before 13th August, 1888, for not less than three years a Medical Officer or Inspector of the Local Government Board.

The duties of the office comprise (*a*) the duties of a Medical Officer of Health as defined by the Public Health Act, 1875, the Orders of the Local Government Board, and the Huddersfield Local Acts; and (*b*) the superintendence of the Infectious Diseases Hospitals of the Borough, including the Sanatorium now in course of construction.

The appointment will be made subject to the approval of the Local Government Board, and in accordance with the Orders of the said Board, and all applications will be considered subject thereto.

Applications, in writing, stating the age of the applicants, endorsed "Medical Officer of Health," with copies of not more than three recent testimonials (which will not be returned), to be sent in to the undersigned not later than the 7th July, 1896, on which day the Council will proceed to appoint such Medical Officer.

By order.

F. C. LLOYD, Town Clerk.

Town Hall, Huddersfield, 12th June, 1896.

Resident Junior House Surgeon.—

Wanted, for the CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY, Chesterfield, a gentleman to fill the office of Junior House Surgeon and Dispenser. He must be fully qualified. Salary £50 per annum, with board, apartments, and laundress.

ASSISTANT in PHYSIOLOGY to be appointed in July. Salary £150, rising by annual increments of £25 to £200.—Applications, with testimonials, to Professor MAC WILLIAM by July 13th.

Taunton and Somerset Hospital.—

HOUSE SURGEON.—The office of House Surgeon at this institution will shortly become vacant. 100 beds. Nursing institute attached. Salary £100 per annum, with board, lodging, and washing in the hospital.

Candidates must be duly registered as possessing both a Medical and surgical qualification.

The candidate elected will be required to enter into an engagement for not less than three years, in case the Governors shall so long require his services, and to commence his duties on July 30th next.

Applications, stating age, certificates of registration, and copies of testimonials, to be sent on or before July 13th to the undersigned.

The election will take place on July 23rd next.

Candidates will not be expected to attend unless they receive notice from the committee.

J. H. BIDDULPH PINCHARD, Secretary.

Dated, 13, Hammet-street, Taunton, 15th June, 1896.

Sheffield General Infirmary.—

Wanted, a JUNIOR ASSISTANT HOUSE SURGEON, who must possess a legal Medical and Surgical qualification from some University, College, or licensing body in the United Kingdom.

Salary £50 per annum, with board, lodging, and washing. Such appointment to continue for three years only, but subject to a three months' notice on either side at any period; nevertheless, such Junior Assistant House Surgeon shall be eligible for re-election.

The offices of HOUSE SURGEON at a salary of £120, HOUSE PHYSICIAN at £80, and SENIOR ASSISTANT HOUSE SURGEON at £60 per annum are also vacant, and the present resident officers will be candidates for these appointments.

Applications and testimonials to be addressed to the "Medical Staff of the Sheffield General Infirmary," to the care of the Secretary, on or before Thursday, July 16th, and a special meeting of the Weekly Board, with whom the election of the before-named medical officers rest, will be held at the Sheffield General Infirmary on Friday, July 31st, at 12 o'clock at noon, when the election will take place.

GEORGE HENRY DAY, Secretary.

Board-room, June 22nd, 1896.

MEDICAL TRANSFER AND PARTNERSHIP

32, Ludgate-hill.

Messrs. Orridge & Co., Medical

Transfer Agents, Referees, and Valuers, in offering their services to the Profession, have pleasure in referring to the fact that for ABOUT HALF A CENTURY the name of Mr. ORRIDGE has been known in the advertising columns of the leading medical journals, and that a very large proportion of the Medical Men throughout the kingdom have confided their interests in the adjustment of PARTNERSHIPS and TRANSFERS to their care.

Purchasers who will communicate (confidentially) the NATURE and EXTENT of their wishes regarding investment can be apprised of appropriate opportunities as they occur.

On occasions where ADVICE is required in forming a correct conclusion as to the worth or eligibility of a Practice, Messrs. ORRIDGE & Co. trust that their familiarity with the various contingencies that govern value will be found of considerable service to those by whom they are employed. N.B.—No charge is made to purchasers.

First-class County Practice, situate

within 100 miles of London. Has been held by vendor nearly twenty years. Receipts average £1500 yearly, including appointments. Very superior house, with garden and tennis lawn. Kitchen, and fruit garden, stabling, &c. Good hunting, &c., in the locality. Introduction about six months. Full particulars on application. About £2500 required.

Apply at Messrs. ORRIDGE & Co.'s Offices, 32, Ludgate-hill.

Lancashire.—Small General Prac-

TICE, situate in close proximity to a large manufacturing town. Present receipts at the rate of £300 yearly, including one or two Club appointments, forming the nucleus of extensive practice. The Practice is worked without horse and well within easy distance. Short introduction only required. Premium £150.

Apply at Messrs. ORRIDGE & Co.'s Offices, 32, Ludgate-hill.

London, near.—Middle-class Prac-

TICE capable of considerable expansion. Present receipts about £340 per annum. Clubs and other appointments have been declined. Premium £450, including the beneficial lease; but if the Practice is taken with a short tenure of the house vendor will accept £300 for the Practice.

Apply at Messrs. ORRIDGE & Co.'s Offices, 32, Ludgate-hill.

THE SCHOLASTIC, CLERICAL, & MEDICAL ASSOCIATION, LTD.

MEDICAL DEPARTMENT.

This Association was established in 1880 as a Limited Liability Company under the direction of professional men, its object being the creation of a RESPONSIBLE and THOROUGHLY TRUSTWORTHY Agency. The Medical Department has met with so great success that it has been found necessary for one of the Managing Directors (Mr. G. B. Stocker) to devote his whole attention thereto; and he has the assistance of an experienced Medical Accountant and a large staff of clerks. Further, a Board composed entirely of gentlemen of high standing in the Medical Profession has been appointed, and to them matters of dispute and complaint are referred.

The Association undertakes the SALE of PRACTICES and PARTNERSHIPS; the Introduction of LOCUM TENENS and ASSISTANTS; MEDICAL ACCOUNTANCY (by a duly qualified Medical Accountant); INVESTIGATION and VALUATION of Practices, &c.; POSTING BOOKS and sending out Bills, &c., &c.

A Pamphlet relating to the Medical Department, with the names of the "Directors" and "The Medical Advising Board," and terms, will sent on application to—MR. G. B. STOCKER,* MANAGING DIRECTOR, 8, LANCASTER PLACE, STRAND, W.C.

Telegraphic Address—"Triform, London."

FOR SALE.

(1) MIDLANDS.—An old-established PRACTICE in a market town of over £900 per annum, including appointments worth £147. Visiting fees 2s. 6d. to 7s. 6d. Very pretty old-fashioned house standing in about three acres of ground, with stabling for five horses, which must be purchased. Price £1200; £800 can remain on mortgage. Premium for goodwill £1300.

(2) HYDROPATHIC ESTABLISHMENT. — PARTNERSHIP and Succession; yielding large net profits; capable of increase. Suitable for retired Army Surgeon or medical man wishing to give up general practice (or non-medical capitalist). Price for lease, furniture, and goodwill, £5000.

(3) FIRST-RATE LONDON SUBURB.—HIGH-CLASS PRACTICE, averaging £2250 per annum. Fees most 7s. and 10s. 6d. Non-dispensing. A year's introduction. Two years' purchase required or offer.

(4) LONDON, W.—Good-class Non-dispensing PRACTICE, established fifteen years. The cash receipts for the last three years average £900 per annum. Visiting fees 7s. 6d. to 10s. 6d. Very little Midwifery. Large, well-appointed house (which need not be taken); rent £175 per annum. Premium £1350.

(5) DEATH VACANCY, London, N. Established sixteen years. Cash receipts for 1895 about £900. One horse required. Small but well-situated house; rent £36. No reasonable offer will be refused.

(6) DEATH VACANCY.—LONDON, S.E.—Old-established PRACTICE. Cash receipts for the last three years average £568 per annum, including appointments of about £220. Visiting fees 2s. 6d. upwards. Very little Midwifery. Good house, situated in main road. Rent £60 per annum. No reasonable offer refused.

(7) DEATH VACANCY.—LONDON, S.E. (main thoroughfare).—Cash receipts for 1895, £553, including club appointments worth £52 per annum. Visiting fees 2s. 6d. upwards. No carriage. The house contains nine rooms. No reasonable offer refused.

(8) DEATH VACANCY.—GOOD RESIDENTIAL LOCALITY. Close to the Thames. Cash receipts for last two years averaged £300, including appointments of £60. Choice of houses.

(9) WEST OF ENGLAND, SEAPORT TOWN.—PRACTICE for immediate Disposal owing to serious illness of vendor. Established sixteen years. The average takings are from £800 to £700 per annum, including vaccination and club appointments. Good house, garden, and stabling. Rent £46.

(10) SOUTH COAST.—Good Residential Town and Watering-place. Non-dispensing PRACTICE. Cash receipts for 1895, £547. Visiting fees mostly 5s. No horse required. Very good house, in the best residential part of the town, with good-sized garden, which would be let for £110 or sold, price £2400 (£1700 of which can be left on mortgage). Premium for goodwill £800.

(11) WEST OF LONDON.—Cash PRACTICE (chiefly working class) of £600 cash receipts for last year. No Midwifery under £1 1s. No horse required; rent £60. Premium £850.

(12) NORTH MIDLANDS.—TOWN PRACTICE of £1600 per annum. Visiting fees 2s. 6d. to 7s. 6d. Two horses. Good house with stabling, rent £70. Premium £1400.

(13) NORTH OF ENGLAND.—Country Town PRACTICE. Cash receipts for 1895 were £1024, including appointments (Union, Colliery, Clubs, &c.) of £400. One horse. Good house, with bathroom and stabling; rent £45. Good society. Educational facilities. Introduction of six or twelve months. Premium £1100.

(14) NORTH OF ENGLAND.—LARGE SEAPORT TOWN.—Good Middle-class PRACTICE of over £500 per annum, including appointments of over £180. Visiting fees mostly 3s. 6d. Good house in a central position, with garden; rent £45. Premium one year's purchase.

(15) WEST RIDING.—Suburb of a large manufacturing town. Old-established PRACTICE of £580 per annum, including appointments worth over £200. Visiting fees, 2s. to 5s. Good twelve-roomed house with stabling, rent £48 per annum. Premium £590.

(16) PARTNERSHIP (one-third or two-fifths share) in a Practice of about £1500 per annum in a good town in the West Riding. Visits 2s. 6d. and upwards. Rent of house to be taken by Partner £50. Premium for one-third £950, to include share of book debts, drugs, &c., or a two-fifths share (without a share of book debts) for £800.

(17) PARTNERSHIP in a good-class outlying Suburban Practice of £875 per annum, with view to succession in two years. Price £930, and a similar sum upon succession.

(18) YORKS.—West Riding, country town PRACTICE of £400 to £450 per annum, including appointments of about £80 per annum. Visiting fees, 2s. 6d. to 5s. No horse required. Good sport, good society. Rent of house with small garden, £20. Premium £450

FOR SALE (*continued*).

(19) NORTH MIDLANDS.—Unopposed country PRACTICE. Cash receipts for 1895, £580, including appointments of over £50 per annum. Visiting fees, 2s. 6d. to 7s. 6d. Good house, with stabling and two gardens, rent £30 per annum. Premium £600.

(20) SOUTH OF ENGLAND.—PARTNERSHIP in a Country Town Practice of about £800 (increasing), including club appointments worth about £200. Visiting fees 2s. 6d. to 10s. 6d. A one-third share would be sold at once for £400.

(21) WESTERN AUSTRALIA. — PRACTICE in an important and rapidly increasing town. The Practice, though only established two years, returned last year £1700, including appointments of £100 per annum. Fees for advice average 7s. 6d. Midwifery fees from £3 3s. One horse required. Premium only £800.

(22) AUSTRALIA.—An old-established unopposed country PRACTICE within easy distance of capital. The cash receipts up to January, 1895, have averaged £1200 per annum, including £250 from appointments. Good fees. Good house, rent £60. Good climate.

(23) LANCS.—Manufacturing town (population over 30,000). Cash receipts for the last three years average £590 per annum, including appointments of about £50. Good house, with stabling and small garden; rent £50. Premium £630, to include book debts, drugs, &c.

(24) WEST RIDING OF YORKSHIRE.—Country PRACTICE of £440 per annum, average cash receipts. Appointments worth over £30 per annum. Visiting fees, 1s. 6d. to 3s. 6d., medicine charged extra. Semi-detached house. Rent £13 per annum. Premium £400.

(25) YORKS.—LARGE MANUFACTURING TOWN.—For Disposal, a CASH PRACTICE (not a Dispensary). Receipts for the last three years average £467 per annum (1895, £510,) including £200 from appointments. Visiting fees 1s. 6d. to 3s. 6d. No horse or assistant required. Good house; rent £50. Premium only £380.

(26) MIDLANDS (in one of the best towns).—Old established PRACTICE of about £400 per annum with great scope for increase. First-rate house, which need not be taken, rent £100. A suitable house could probably be obtained for £42 per annum. Premium £400.

(27) LONDON.—NORTHERN SUBURB.—Cash receipts for 1895 £385. Visiting fees 2s. 6d. to 3s. 6d. Semi-detached villa containing eight rooms &c., with large garden; rent £45 per annum. Premium £425. Vendor is relinquishing to go abroad.

WANTED TO PURCHASE.

(28) WANTED, a PARTNERSHIP in a Practice in Leeds. Purchaser is an M.B. London (Honours), B.S. Age twenty-five, and has ample capital.

(29) WANTED, a PRACTICE or PARTNERSHIP in a Country Town where trout fishing could be obtained. No clubs. Purchaser can invest up to £1500.

(30) WANTED, a Country PRACTICE anywhere South of Nottingham of £700 to £800 per annum. Purchaser is an L.R.C.S., L.R.C.P., Guy's. Experienced, and can invest up to £1000.

N.B.—There are several hundred purchasers on the books of the Association, so that the sale of any good Practice or Partnership within a reasonable time is virtually certain.

MEDICAL PARTNERSHIP AND CONVEYANCING AGENCY.

1, ADAM-STREET, ADELPHI, W.C.

The SALE of PRACTICES and PARTNERSHIPS NEGOTIATED.

Trustworthy LOCUM TENENS and ASSISTANTS can be had at a few hours' notice.

N.B.—No charge made to Purchasers.

Notice.—Mr. J. C. Needes, with an experience of over a quarter of a century, is in an exceptional position to give intending Purchasers independent information concerning most PRACTICES and PARTNERSHIPS. Those investments in the following List marked with an asterisk are well known to him, having been purchased through his Office by the present Incumbents years ago, and in many other cases an introduction can be given to gentlemen who have taken charge of the Practices during the absence of the Incumbents.

UNUSUAL OPPORTUNITY.—COLONIAL.—A gentleman prepared to enter into immediate arrangements can secure for the sum of £250 an old-established PRACTICE, the cash receipts of which last year amounted to £1400. The practice (which has been held by vendor many years) is situated in one of the principal cities in Australia, is non-dispensing, and confined to a comparatively small area. One good horse sufficient. Visiting fees, 10s. 6d., upwards. Midwifery, five guineas. The incumbent (who is the brother of a well-known West-End physician) is now in London, having left the Practice in charge of a locum tenens, who is under a bond not to practise.

*A BARGAIN.—LONDON, S.E.—A well established CASH PRACTICE, returning about £600 a year actual Cash Receipts, for immediate Disposal for the moderate sum of £350. Expenses light. Rent £40. An efficient introduction.

£1000 PER ANNUM.—A good-class Country PRACTICE in a beautiful district about 100 miles from London and within easy reach of a fashionable town can be secured by a suitable Gentleman, who should be at least thirty years of age, married, and of good address. Nearest opponent five miles distant. Fees good, expenses light, and the Practice easily worked. Railway station in place. Moderate-sized house. An efficient introduction given.

JUNIOR PARTNERSHIP.—SOUTH COAST.—A young energetic gentleman required to purchase a small share (yielding £200 to £300 a year at present) of a rapidly-increasing middle-class, situated in favourite watering place. Expenses light. Further particulars on application.

CUMBERLAND.—Totally unopposed, the nearest Medical Man residing eight miles distant. Cash receipts last year over £400, including Appointments £110, certain of transfer. Picturesque district, hunting, fishing, and shooting. Small house, with stabling, greenhouse, and garden attached. Rent low. An introduction given to meet wishes of purchaser.

*SEASIDE.—In a large and fashionable Watering-place, within a few hours' run of London, an old-established PRACTICE, estimated to be worth between £600 and £650 per annum, including Appointments £115. The connexion comprises both residents and visitors. No Midwifery under a guinea. Large family residence facing the sea, containing two reception-rooms, eleven bedrooms, consulting-, waiting-, and dispensing-rooms, &c. Rent moderate. Premium £800. An efficient Partnership. Introduction given.

CASH PRACTICE situated in a large town about 100 miles from London. Residence on the premises is not necessary, the present incumbent residing in a pleasantly situated house in the suburbs of the town. The cash receipts for the past four years average £900 per annum, last year £925. Three months' introduction given. Premium £900.

*SOUTHERN COUNTY.—In a charming and prosperous district an old-established, unopposed PRACTICE worth £650 per annum, inclusive of Union and Club appointments. Average fee for visit and medicine, 5s. Fifty cases of midwifery. One horse sufficient. Detached house, with large garden and stabling. Three months' introduction given. The district possesses many advantages, is increasing, and offers good future prospects.

TWELVE MONTHS' PARTNERSHIP INTRODUCTION will be given to an old-established PRACTICE in a small, pleasant town, containing nearly 2000 inhabitants, forty miles from London. It at present produces between £400 and £500 per annum, and is capable of very considerable increase by a younger and more energetic successor. Appointments (guaranteed) yield about £200. There is a railway station in the place, and the nearest Medical Man resides four miles distant.

Apply to J. C. NEEDES, 1, Adam-street, Adelphi, W.C.

Practice required of £400 to £600 a year (unopposed and with Appointments attached) in the South Midlands or Western Counties. Any gentleman desirous of relinquishing a Practice of the above description can meet with an immediate purchaser prepared with cash on communicating particulars in confidence to J. C. Needes.

Locum Tenens and Temporary ASSISTANTS.—Practitioners requiring the above can immediately obtain thoroughly reliable qualified Gentlemen upon application to 1, Adam-street, Adelphi, W.C. Every Gentleman engaged by the Office in either of the above capacities is personally known to Mr. J. C. Needes. An office fee of half a guinea is payable by the Principal.

Mr. Herbert Needes (son of the late Mrs. Needes, and for more than ten years associated with her in the management of this old Agency) is still carrying on the Business, and will be glad to negotiate the Transfer of PRACTICES and PARTNERSHIPS on the usual terms. No connexion with any other office.

LOCUM TENENS.—Reliable Gentlemen always on the Books.

ASSISTANTS provided free of charge to Principals.

1. MIDLANDS.—Good class PRACTICE situate in a country Town within eighty miles. Receipts average £930 per annum ('95 over £1000), including £150 from appointments. The connexion is the leading one in the locality and no Assistant is required. Old-fashioned family residence standing in three acres of grounds. An efficient introduction given. Premium £1400.
2. £800 PER ANNUM, INCLUDING £250 FROM APPOINTMENTS.—The PRACTICE is situate in a pleasant Country Town about three hours' run from London and is well known to Mr. Needes. Opposition nominal. Patients mainly agricultural with sprinkling of gentry, clergy, &c. Convenient house with garden and stabling. Rent £40. Six months' introduction given.
3. IMMEDIATE.—A gentleman practising in a northern suburb, who is leaving England, wishes to transfer his increasing CONNEXION, which returned last year nearly £500. Good house with large garden, but successor has the option of taking another. Price only £350.
4. CROYDON.—For prompt Sale, a small Private PRACTICE with detached Surgery. Joint rentals £40 per annum. Would suit a young practitioner commencing. About £150 required.
5. COUNTY TOWN WITHIN FORTY MILES OF LONDON.—For Sale, with an introduction to Michaelmas, a well-established PRACTICE held by the Vendor four years and returning under adverse circumstances over £300 a year. Good scope for an active man. Successor can have choice of residences, at moderate rentals. Premium £250.
6. NORTHERN SUBURB.—A good Partnership introduction given to a superior class old-established PRACTICE returning £500 a year, with ample scope for extension. Visiting fees 5s. to 21s. Little midwifery. Good corner family residence in thorough repair. Moderate premium from a prompt purchaser.
7. WITHIN TEN MILES OF LONDON, a small, well-established PRACTICE, held by the vendor over seven years. Receipts last year nearly £300. There is a very good residence built for the incumbent, large garden; rent £60. Premium only £250. An active man would find ample scope for extension.
8. CASH PRACTICE situate in an eastern suburb held by Vendor seven years and realising last year £370. Expenses moderate and radius of work small. Convenient private house well situate, rent £34. Premium, with an efficient introduction, £250.

Telegrams: "CURANDUS," London.

Louth, Lincolnshire. — To be Let with immediate possession, Upgate House, containing nine bedrooms, dressing-room, bath-room, w.c., dining, drawing, and breakfast rooms. Good kitchens, cellars, surgery, stabling for six horses (three loose boxes), carriage house, harness-room, &c. For over thirty years occupied by the late T. James Esq., surgeon, and his successor.—Apply, C. R. Surfleet, Auctioneer, &c., Louth, Lincolnshire.

BOURNEMOUTH.—CANFORD CLIFFS ESTATE, overlooking the English Channel, Solent, and Bournemouth Bay.

Messrs. Philip and George Geen will OFFER by AUCTION, in a Marquee on the Estate, on Thursday, July 2nd, 1896, at 3 P.M., several excellent FREEHOLD BUILDING SITES, ripe for the erection of good Villa Residences and Shops. The Plots vary in extent and possess frontages to excellent roads. The Estate occupies a most healthy position about 120 feet above the sea level, and a fine stretch of sand extending to Bournemouth Pier affords an excellent and easy walk into the town. A natural harbour within a mile forms a well sheltered anchorage for yachts. The property fronts the sea and overlooks pleasure grounds set aside under covenants by the Estate owners. Magnificent pine woods form a valuable protection from the north and east winds, which has caused the Estate to become known as the Mentone of England. Free conveyances. Payments by easy instalments. Luncheon will be served prior to Sale. Cheap railway tickets (not transferable) can be obtained of the Auctioneers.—Printed particulars, plans, and conditions of sale can be had of H. R. Hutchings, Esq., Solicitor, Grosvenor-chambers, Bournemouth; Messrs. Pinder & Fogerty, Architects, 2, St. Peter's-terrace, Bournemouth; or of the Auctioneers, 55, Waterloo-road, London, S.E. Telephone 45,007.

Unique position for a Medical Man in best part of Bournemouth, exactly opposite railway station on main line, and commanding a large and rapidly increasing new neighbourhood. Three reception, eight bedrooms, large hall. In one acre, on the main high road. Freehold £2500, or might let.—Owner, Dolphcot, Parkstone, Dorset.

Consulting-rooms in Grosvenor-street, W., to Let. Large, furnished, and well lighted. Good attendance and share of commodious, well-furnished waiting-room. Immediate occupation. Suitable for Consultant Physician or Surgeon. —Address, Narcotine, THE LANCET Office, 423, Strand, W.C.

To Medical Men.—Capital corner 18-roomed house, facing main road, close to rail and bus, in good neighbourhood, for many years occupied by a doctor, side entrance, surgery, &c. No premium. Rent £70, or could be purchased.—Apply Willmott, 63 and 65, Goldhawk-road, W.

Wanted, Practice or Partnership of about £400 to £600 a year, with appointments. Good house and garden.—Particulars to M. J., THE LANCET Office, 423, Strand, W.C.

City Practice. — A well qualified Gentleman wishes to hear of a genuine City Practice (with Appointments preferred), or a Share in such a one would be entertained.—Address, G. T. C., THE LANCET Office, 423, Strand, W.C.

To Gentlemen Retiring or requiring a Partner.—A successful Practitioner, aged thirty-nine, in large Practice in the South, and wishing to live in London or the Suburbs, is desirous of meeting with one of the above within the next twelve months, or would Exchange his own Practice for a Partnership near Town. Income required £600, and upwards. Advertiser has ample capital. Any replies considered strictly confidential. No agents.—Apply, Messrs. Lanfear, Tanner, and Lanfear, Solicitors, 110, Cannon-street, City, London.

South East of England.—Very old-established PRACTICE of £600 per annum, consisting of middle-class, private, and club, &c., appointments. Share for Disposal, with ultimate Succession to the whole. Suit a practitioner with some private means.—Delta, THE LANCET Office, 423, Strand, W.C.

Partnership, S.W. County (One-third or Two-fifths Share, with larger share in five years).—PRACTICE about £1300 per annum in a small town situate in a lovely country district, with good hunting. House, rent £40. One horse sufficient, supplemented by bicycle. Would suit an energetic well-qualified man about thirty, who should be married. Premium two years' purchase.—Address, Howitt, THE LANCET Office, 423, Strand, W.C.

Working Partnership required near London, by a doubly qualified general practitioner. Many years' experience in hospital, private, and club practice. Accustomed to good-class patients. Well received. Return, without investment, about £200, with option of further share by purchase.—A. B., care of Ellis, Stationer, 32, High-street, Tooting, S.W.

Partnership, pleasant Suburb of London.—The Half-share of a good Middle-class and increasing Practice for immediate Disposal. Receipts over £700. An energetic Gentleman about thirty with some means preferred. Succession to the whole may probably be secured after a time. Premium £700.—Address, with particulars, L. P., THE LANCET Office, 423, Strand, W.C.

A Partner required to help Medical Man in delicate health. Must be a Gentleman who would be well received by ladies, and prepared to pay for half-share, with the option of buying the whole in time.—Apply, M. M. C., 39, Bramley-road, Notting-hill, London, W.

Any reasonable offer.—A cheap Cash PRACTICE in thickly populated neighbourhood in E.C. district, non-resident. Few hours a day only. Transferable club covers expenses. Average receipts this year £2 5s. per week. Have been considerably more. Could be expanded by man who would devote his whole time to the work and take up Midwifery.—J. B., THE LANCET Office, 423, Strand, W.C.

Junior Partner wanted in a West-end Practice between £1000 and £1200 per annum. Must be well qualified and one having some connection in the West-end preferred.—Address, Theta, THE LANCET Office, 423, Strand, W.C.

Dispensary for Sale in large Pro-vincial Town. Cash takings average over £5 per week. No residence, nightwork, or midwifery. Low rent. Scope for increase. Price £50, to include surgery, furniture, and drugs. Genuineness guaranteed.—Address, Omega, THE LANCET Office, 423, Strand, W.C.

For Sale, within 10 miles of Manchester, small but increasing PRACTICE. Last year's receipts over £260, but capable of great increase. Opposition slight. Expenses small. Every investigation allowed.—Address, Lancs, THE LANCET Office, 423, Strand, W.C.

Surgery for Sale in a thickly populated neighbourhood, only opened a few months. Vendor has not time to attend to it, having another practice.—Address, A. K., 4, Church-street, Shoreditch.

Cash Practice for Sale. Open Surgery. Main thoroughfare. Scope for increase. Fees from 1s. Large town in Yorkshire. Income over £200 per annum. Rent £26, Premium £60.—Address, Surgeon, THE LANCET Office, 423, Strand, W.C.

For immediate Disposal, a Country PRACTICE of over £600 a year, inclusive of transferable appointments. Is in a pleasant agricultural district in the West Midlands, and would suit a young man fond of country life.—For further particulars address, Rural, THE LANCET Office, 423, Strand, W.C.

For Disposal, well-established Prac-TICE, about £700 a year, in South-western country town. Charming district, fishing, hunting, &c., pleasant society, and other advantages. Price £1550, to include horses, traps, furniture, &c. No agents.—Address, Veteran, THE LANCET Office, 423, Strand, W.C.

London, W.—For immediate Dis-posal, the owner being unable to give it enough attention by reason of engagements elsewhere, a small Cash NUCLEUS, recently established, yielding about £1 per week but readily capable of immense increase. The house is in good condition and is in a main road in the centre of a large working-class population; rent £35 on agreement, part could be let off. Furniture, fittings, and drugs are worth about £45. Open to offer, or a preliminary Assistantship with view to purchase or Partnership would be entertained.—Address, Calomel, THE LANCET Office, 423, Strand, W.C.

Lancashire.—To be disposed of cheap, a good reliable PRACTICE, doing £350 cash per annum. Satisfactory reasons for leaving.—Address, M., THE LANCET Office, 423, Strand, W.C.

Increasing Nucleus. — Established two and a-half years, S.W. district. Receipts for this year to date over £50. Has not been well looked after, but there is plenty of scope for an energetic man, who would take midwifery and night work.—Apply, Medicus, 162, Ladbroke Grove, W.

Medical Practice in Johannesburg for Sale (office business only). Net profits over £3500 per year. Will stand a thorough investigation. Reason retiring from practice.—Address, Ernest Korne, Esq., P.O. Box 510, Johannesburg, S.A.R. Price £4000.

For immediate Disposal, small PRACTICE, good residential neighbourhood near London; plenty of scope. Easy terms to prompt purchaser.—Address, Nemo, THE LANCET Office, 423, Strand, W.C.

£75 will be accepted for the furni-ture, fittings, drugs, &c., of a good Dispensary PRACTICE, situated in North London. Returns from £250 to £300 per annum (without midwifery, which if taken would easily double the receipts). Established over two years. A death the sole cause of disposal.—Address, Serio, THE LANCET Office, 423, Strand, W.C.

Locum Tenency desired by qualified registered gentleman, experienced. Repeated engagements with the same principals. Total abstainer and non-smoker. Aged thirty. Disengaged.—F. A., 56, Antill-road, Bow, London, E.

A doubly qualified University Graduate, registered, desires engagements as LOCUM TENENS. Advertiser is of considerable experience, and has had charge of several Practices in London and the country. Good testimonials and references.—Address, Zeta, THE LANCET Office, 423, Strand, W.C.

A qualified Man attending hospital would give his mornings and evenings in return for comfortable Home in or near London. Good references.—Address, Hospital, THE LANCET Office, 423, Strand, W.C.

Dentist (registered) having some spare time wishes to arrange with a Surgeon or Chemist, daily or otherwise attendance for mutual advantage. London or district.—Address, Dentist, THE LANCET Office, 423, Strand, W.C.

It is very explicit."—THE LANCET, February 9th, 1895. It contains all the conditions of the usual bond as well as several useful and necessary clauses. Stamped copies, price 11s. Entered at the Stationers' Hall, and can only be obtained from RICHARDSON BROS. & CO., Medical Agents, Liverpool. ASSISTANTS and LOCUM TENENS supplied.

NOTICE.

WITH regard to advertisements affecting unqualified assistants, the Proprietors of THE LANCET think it right to point out that they obviously cannot guarantee that each individual advertiser offers his services under such conditions as would be approved by the General Medical Council. The Proprietors consider that inconvenience to practitioners and hardship to unqualified assistants may be caused by the entire exclusion of these advertisements from the columns of THE LANCET. The General Medical Council do not, it is understood, object to unqualified assistants being employed by practitioners when resident in or near their employers' houses, but the Council will not allow unqualified persons to conduct branch practices, or dispensaries which are situated at a distance from the principal's house and are not under his immediate supervision.

Dispenser.—Wanted, Senior Student to Dispense about one hour in afternoon, and occasionally fill a gap out-door (near Oxford-circus).—Address, Colcum, Willing's Advertising Offices, 162, Piccadilly, W.

Dispenser wanted, out-door, for a firm of Surgeons in a Provincial Town.—Apply, by letter only, to X., care of Wyman & Westwood, 58 & 59, Bunhill-row, E.C.

Wanted, an unqualified Assistant (in-door), for short period, to help a Doctor in an East-end Practice. Must be able to attend Midwifery and a quick and accurate Dispenser. Fourth years' student preferred. Time for reading.—Apply, stating terms &c., to Alpha, THE LANCET Office, 423, Strand, W.C.

Wanted, a Man about 30 as a DISPENSER. Able on an emergency to see patients or Visit. Married preferred, no children. Unfurnished rooms and 25s. a week to begin with.—Address, by letter only, X. Z., care of Mr. Hill, chemist, Well-street, South Hackney.

Medical Student, experienced Dispenser, accustomed to Midwifery and Visiting, requires SITUATION in-doors. Time required for hospital attendance. Highest references.—Address, Permanency, THE LANCET Office, 423, Strand, W.C.

Assistancy.—Gentleman, full curriculum, and reading for final, well up in Midwifery and General Practice, and a neat, accurate, and expert dispenser, wants engagement about 1st August, splendid references.—Address, Medicus, THE LANCET Office, 423, Strand, W.C.

Wanted, by a fourth year's student of London Hospital, with full curriculum, aged thirty-six, an ASSISTANTSHIP. Visiting, midwifery, and dispensing. Several years' experience.—Address Medicus, care of Miss Burne, 130, Edgware-road, London, W.

Out-door Assistancy wanted by a married Gentleman without incumbrance. Several years' experience in Private, Union, Club, and Colliery practice. Good Accoucheur and Dispenser, and accustomed to keep Books. Permanency desired. Now disengaged.—Address, Norfolk, THE LANCET Office, 423, Strand, W.C.

A Swede, fully qualified and licensed in Sweden to practise the Manual or Movement Treatment, asks if there is any Doctor in London who will take up the treatment and give him EMPLOYMENT.—Further particulars by letter to F. W., THE LANCET Office, 423, Strand, W.C.

Translations of Medical Works, &c., from the German or French into English are done by a German, an Undergraduate, London, and qualified in Surgery, Forensic Medicine, and Midwifery. Address, M. N., THE LANCET Office, 423, Strand, W.C.

("INGLUVIN.—A powder from the gizzard of the chicken (*Ventriculus callosus gallinaceus*) prescribed in the same manner, doses, and combinations as Pepsin."

Per oz., 4s. 0d., prepared by W. R. WARNER & Co. Wrapper, design, and word "INGLUVIN" registered under the Trade Marks Act.)

A VERY appropriate name for this remedy is **INGLUVIN.** It is the essential principle of the gizzard, and bears the same relation to poultry that pepsin does to the higher animals. The honour of its discovery and utilisation, in its crude state, remotely dates with the Chinese gastronomer, as well as (in its refined condition) to the Caucasian chemist. From time immemorial the inhabitants of the Celestial Empire have used the gizzard of chickens and ducks in nearly all made dishes. Their writers have recommended the practice as a sovereign treatment of dyspepsia, weak stomach, and vomiting. A favourite prescription of Chinese physicians for chronic indigestion is to cut up and digest chicken gizzards in hot water until they are reduced to a pulp, and then add some spices. A tablespoonful or two of the resulting paste is taken at each meal until the patient has entirely recovered. From China the practice passed to other parts of Asia, and was adopted here and there among the Mediterranean peoples. Strange to say, it was never learned by the great nations of Europe until the latter part of the present century. On the other hand, the organic chemists of Europe discovered, about 1850, a powerful nitrogenous radical in the gizzard. Experiments thereafter showed it to possess many of the qualities of pepsin. These experiments led to its isolation. Numberless experiments have proven it to be a very valuable addition to therapeutics. Where pepsin refuses to act, and where in severe cases it has even been rejected by the stomach, **INGLUVIN** effected relief rapidly and with the greatest ease.

In four cases of poisoning by root beer (Brooklyn, June, 1886), Dr. GEORGE EVERSON, Jr., a well-known physician of that city, reports that after pepsin and all similar compounds had been rejected by the stomachs of his patients **INGLUVIN** stayed the retching and enabled them to retain and digest food.

Dr. LASSING reports a similar experience in several cases of acute dyspepsia.

A priori, it would seem as if **INGLUVIN** should be more efficient and potent than pepsin in many cases of physical disorder.

Our poultry are chiefly granivores, and have no beak or other buccal apparatus for crushing the hard grain and seeds on which they so largely feed. The food is swallowed when apprehended, and passes directly into the crop or gizzard. This seems to act both mechanically and chemically. Its interior walls are covered by a dense, hard membrane, surrounded by muscles of the most powerful type. Along with the food is always a small amount of sand and gravel. The organ acts apparently by bruising and cracking, rather than, as is commonly believed, by trituration. The motion of the ingluvial muscles is accompanied by a slow but continuous exudation, from the walls of the crop, of a strong organic fluid, of which **INGLUVIN** is the chief constituent. The hull of the grain, or the shell of the seed, is broken by the pressure of the walls and the gravel, and their interior is exposed to the chemical action of the **INGLUVIN.** By the time it reaches the stomach it is ready for the gastric juices. From this point on, digestion proceeds as with the higher animals. As the gallinaceæ have very small salivary glands, and as the fluids secreted by these resemble the secretion of the parotid rather than that of the sublingual and submaxillary glands of the human being, it would seem as if **INGLUVIN** played a double part, exercising the functions of the ptyalin of the saliva as well as the pepsin of the stomach. **INGLUVIN** is prepared by WM. R. WARNER & Co., Pharmaceutical Chemists. It is made from selected gizzards, and is so carefully extracted as to be free from all foreign organic bodies. It is already known and appreciated by the Medical Profession. The AMERICAN ANALYST bespeaks for it the same appreciation by its readers. We extract the following:—

"Prof. ROBERTS BARTHOLOW, M.A., M.D., LL.D., in his late work on 'Materia Medica and Therapeutics,' says:—**INGLUVIN:** This is a preparation from the gizzard of the domestic chicken—*ventriculus callosus gallinaceus.* Dose, gr. v.—℈ j.

"**INGLUVIN** has the remarkable property of arresting certain kinds of vomiting—notably the *vomiting of pregnancy.* It is a stomachic tonic, and relieves *indigestion, flatulence*, and *dyspepsia.*

"The author's experience is confirmatory of the statements which have been put forth regarding the exceptional power of this agent to arrest the vomiting of pregnancy. It can be administered in inflammatory conditions of the mucous membrane, as it has no irritant effect. Under ordinary circumstances, and when the object of its administration is to promote the digestive function, it should be administered after meals. When the object is to arrest the vomiting of pregnancy it should be given before meals."—*From the* AMERICAN ANALYST, *August 1st, 1886.*

The PUMP HOUSE, LAKE HOTEL, and BATHS,

LLANGAMMARCH WELLS, CENTRAL WALES.

Telegraphic Address—"BARIUM, LLANGAMMARCH WELLS." [For Terms apply to MANAGERESS.

(CENTRAL WALES.) **BARIUM SPRINGS.** (ALTITUDE 600 ft.)

THE LLANGAMMARCH WELLS, PUMP HOUSE, LAKE HOTEL AND BATHS. This first-class Hotel standing in its own ornamental grounds, is situated on the slope of the Eppynt Hills, looking down one of the most beautiful valleys of Wales. All the rooms have been furnished with every regard to the comfort of visitors; special attention has also been given to the sanitary drainage and water supply, which has been carried out on the most modern principles. There is splendid Salmon and Trout Fishing to be obtained in the River Irfon, over two miles of this charming tributary of the Wye flowing through the hotel grounds and is reserved for visitors, who also have the privilege of shooting over several thousand acres of Mountain and Moorland, while the picturesque lake affords every facility for boating.

It has been stated in a recently published work on Chronic Diseases of the Heart, as the result of experiment, that the Mineral Waters of Llangammarch, employed as baths as well as taken internally, exercise healing effects similar to those of the celebrated springs of Nauheim and Kreuznach in Germany. The Proprietors of the Llangammarch Wells have, therefore, secured the attendance at the Pump Room and Bath House, during the season, 9th March to October, of a Physician, who is practically acquainted with the various methods employed for the relief of Gout, Rheumatism, and Heart Affections, including those advocated by Dr. Schott at Nauheim.

A trained nurse, who administers massage under Medical Supervision, will also be in attendance.

RESULT OF ANALYSIS BY DR. DUPRÉ, August, 1883:—

"A Sample contained in two Winchester quart bottles, stoppered, from Llangammarch Springs. The water is clear, slightly saline taste.

Chloride of Sodium	189·56
Chloride of Calcium	84·56
Chloride of Magnesium	24·31
CHLORIDE OF BARIUM	6·26
Carbonate of Calcium	2·80
Silicia	1·40
	308·89 grains per gallon.

"The characteristic feature of the water is the presence of a notable quantity of BARIUM CHLORIDE and a consequent total absence of sulphates. BARIUM is a rare constituent of Mineral Waters.

"*Westminster Hospital, August 23rd, 1883.*" "A. DUPRÉ.

As a remedial agent **BARIUM** ranks high in cases of Strumous Disease in its protean forms, Glandular Enlargements, Scrofula, Chronic Rheumatism, Epilepsy, and Diseases of the Heart. It is also useful in other Diseases, such as Liver Derangements, &c.

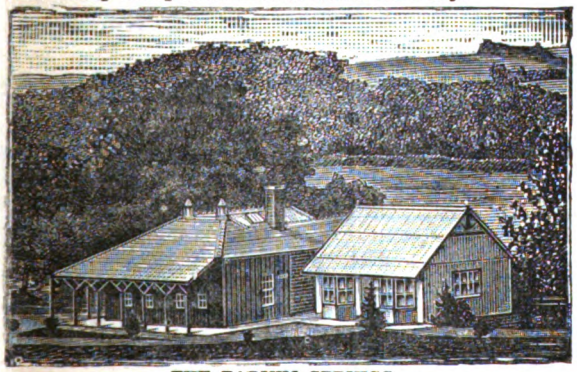
Extract from THE LANCET, Nov. 24th, 1894:—

"A sample of the barium water was obtained, sealed, and despatched to THE LANCET Laboratory for detailed examination, and the results may be compared with the analysis of the sample first submitted. In the following analyses Sample 1 is the sample obtained by ourselves, and Sample 2 the sample first submitted. The results are expressed in grains per gallon (70,000 grains):—

	No. 1.	No. 2.
Chloride of barium	6·749	6·490
Chloride of sodium	186·200	185·900
Chloride of calcium	85·160	85·470
Chloride of magnesium	20·100	20·315
Chloride of lithium	0·847	0·910
Chloride of ammonium	0·262	0·262
Alumina and silica	3·340	3·100
Bromine as bromide	Distinct traces	Distinct traces
Total mineral matters	302·658	302·447

"It is important and interesting to observe that the quantity of barium salt has varied only within very small limits during the last ten years, as in 1883 Dr. Dupré made an analysis, in which he found 6·26 grains of barium chloride per gallon. The amount of chloride of barium may therefore be fairly regarded as constant—a fact which is of especial importance in view of the powerful action of barium salts. ..... The quantity of barium present renders the internal administration of the Llangammarch waters quite safe, and no harm could result from drinking the water in reasonably large amounts. One tumblerful is a sufficient dose in most cases and two tumblerfuls should seldom, if ever, be exceeded though the dose may be repeated three or four times a day."

THE LAKE, LLANGAMMARCH WELLS.



THE BARIUM SPRINGS.

Extract from the MEDICAL ANNUAL, 1890:—

"*Heart—new treatment.*—Continued trial has affirmed the efficacy of **BARIUM CHLORIDE** as a cardiac tonic. It has been found to slacken and regulate the heart-beat and to augment the amplitude of the pulse without producing as much increase in the arterial tension as does digitalis. Da Costa and Hare have both added their experience of the drug to the published statements of Boehm, Kobert, Bacey, Lauder Brunton, and Bartholm on this subject. Da Costa finds that it can be taken for a long time without disordering the stomach, that it has some diuretic action, and that it has the valuable property of lessening cardiac pain—a statement which Hare confirms. The latter has obtained good results from the use of Barium Chloride in both mitral diseases, in acute dilatation of the heart, and in functional derangement of the heart. H. A. Haze (JOURNAL DE MÉDECINE DE PARIS) has obtained good results from its use in all the above diseases, and also in aortic diseases.

"*Glandular Enlargement.*—An eminent London Physician writes:—'My experience in the two cases which I sent to Llangammarch has been eminently satisfactory, and the well-recognised efficacy of the Kreuznach waters in glandular enlargement encourages the hope that the waters of Llangammarch may prove to be of signal and widespread benefit in the future.'"

BARIUM WATER is supplied, both Still and Aerated, by the London Agents—

INGRAM & ROYLE, Ltd., 52, Farringdon St., E.C. [Telegraphic Address "Ingram Royle, London."

SQUIRE'S CHEMICAL FOOD.

Known for 30 years as the best preparation of its kind

FOR DELICATE CHILDREN.

The Profession is cautioned against imitations, which differ in strength both from the original and one another in the most essential ingredients.

SYRUP OF SENNA.

A mild Aperient for Children, pleasant in flavour. Since its introduction, a quarter of a century ago, has been in continuously increasing demand.

CONFECTIO BELÆ RECENTIS.

A valuable remedy in Chronic Diarrhœa and Dysentery. Prepared in this country from Bael Fruits, Imported ripe and fresh in their Natural State.

DOSE—A Tablespoonful.

"It possesses all the aroma of the fruit, and is not only astringent where diarrhœa exists, but possesses the singular property of being aperient if the bowels be irregular or costive."

Messrs. SQUIRE'S preparation is all that can be wished."—THE LANCET.

KASAK ELIXIR.

A Tonic Laxative — reliable, palatable, uniform in strength — without constipating reaction.

DOSE—For a Child, one or two Teaspoonfuls (according to age) at bedtime or in the early morning.

For an Adult, one Tablespoonful.

ALSO

KASAK PILULES. KASAK CAPSULES.

LIQUOR MORPHIÆ BIMECONATIS.

Syn.: LIQUOR MECONII.

A purified Solution of Opium with the Alkaloids in their natural state of combination, and standardised to contain 1 p.c. of Morphia.

NOTE.—The B.P. Solution, made by dissolving Morphia in Meconic Acid, differs very considerably from the above, and is no substitute for it.

LEHLIA.

The New and Admired Toilet Requisites.

LEHLIA Cream. Emollient for Face & Hands. 1s.

LEHLIA Dentifrice. A Perfect Tooth Powder. 1s.

LEHLIA Dusting Powder. For Nursery and Toilet. 1s.

LEHLIA Extract. For Use after Exposure to Sun or Cold Winds. 1s.

LEHLIA Soap. Pure and Refreshing. In boxes, containing 3 cakes, 2s.

SQUIRE & SONS,

HER MAJESTY'S CHEMISTS,

413, OXFORD STREET, LONDON, W.
